A

Abderhalden reaction, the, 830
Abdomen, War Surgery of (Col. C. Wallace) (review), 392
Abdominal evacuation of pregnant uterus before viability (Dr. V. Bonney), 518; surgery (Sir J. Bland-Sutton), 594
"Abdulla" Almanack, 1919, 864
Abel, Dr. E. L., new laryngotome and tracheotome, 746
Aberdeen University, pass lists, 92
Abnormalities, inheritance of (leading article), 751
Abrahams, Maj. A., and Dr. F. N. Hallows, rapid decease in young men, 239
Achard, Prof. C., microbic diversity of the enteric fevers, 393; and M. Léon Binet, migration of metallic bodies in the circulatory current, 463
Acidosis in disease (Dr. E. P. Poulton), 31
Adami, Col. J. G., inheritance and acquirement of disease, a study of the rejected, 744
Adams, Capt. J. E., rôle of the scapula in thoracoplasty, 351
Adams, Mr. J., treatment of ante-natal and post-natal syphilis, 707, 770
Adamson, Dr. H. G., disappointment of vaccine therapy, 172
Adenoids, device for prevention and treatment (Dr. Isabel Ormiston), 240, 245; nasal drill in the treatment of, 370, 405, 434
Aeroplane, a radio-surgical, 532
Aero-urethroscope, new, 110
After-care and colony treatment (Mr. P. C. Varrier-Jones and Col. G. S. Woodhead), 133
Agglutinating properties of antityphoid sera (Mr. T. T. O'Farrell), 626; a correction, 831
Ailments, common, of women, treatment, 849
Albumin reaction in sputum, 96
Alcohol injection, risks of, for trigeminal neuralgia, 56
Alcohol, pharmacology of (Maj. R. B Wild), 623; and glycerine, release of, 789; for influenza patients, 890
Alexander, Maj. G. F., operation for the cure of pterygium, 488
Allan, Capt. N. J., R.A.M.C. (see Obituary of the war)
Allen, Dr. C. W., Local and Regional Anæsthesia, second edition, 1918 (review), 671
Allen, Dr. R. W., influenza and preventive inoculation, 603; treatment of influenza, 644
Allingham, Mr. W., treatment of influenza, 644
Almond, Capt. G. H. H., R.A.M.C. (see Obituary of the war)
Alvarenga prize, 785
Ambrine candles, 672
Ambulance Department of St. John Ambulance Association, 829
Ambulance workers, voluntary, national tribute to, 795, 823
American poison plants, 30; help in French puericulture, 789
American Review of Tuberculosis (review), 48, 109, 330, 886; Addresses (Sir B. Moynihan) (review), 359
Amœbic and bacillary dysentery, macroscopic and microscopic methods of diagnosing (Capt. J. G. Thomson and Capt. L. F. Hirst), 448; types of dysentery bacilli isolated (Capt. J. G. Thomson and Capt. L. F. Hirst), 449; amœbic dysentery (Capt. J. G. Thomson), 451; dysentery infection, examinations for, 724
Anæsthesia and shock (Dr. E. P. Poulton), 31; ether, for face and jaw surgery (Capt. J. C. Clayton), 454; universal, 529
Anæsthesia, lumbar, in treatment of sciatica, 52; general, in facial surgery, 56, 125; Local and Regional (Dr. C. W. Allen), second edition, 1918 (review), 671; local, and twilight sleep in exophthalmic goitre (Mr. S. H. Rouquette), 776; spinal, present position, 819, 861; local, for empyemas (Dr. C. W. Morris and Dr. L. Horsley), 880
Analgesia, spinal, in gynæcology, routine use Dr. N. Mahfouz Bey), 141, 150

ANALYTICAL RECORDS FROM "THE LANCET" LABORATORY—

Ambrine candles, 672
"Clarocit," 210
Coffee perlettes, 16
Collosol cuprum, 16
Dried milk (Ambrosia brand), 210
Evatmine, 672
Fermentose, 672
Fly-quit products, 210
Hay fever outfit, 210
Kinectine, 16
Milk, dried (Ambrosia brand), 210
Morubiline, 672
Névros thénine (Freyssinge), 672
Sotol, 672
Stannoxyl, 16
Quinéine, 672

Anatomy, Descriptive and Applied (Mr. H. Gray) twentieth edition, 1918 (review), 709; Applied (Dr. G. G. Davis), fourth edition, 1918 (review), 746
Anatomy, morbid (Prof. G. F. Still), 193
Ancient physic, 507
Anderson, Capt. J., R.A.M.C. (see Obituary of the war)
Anderson, Dr. W. D., similar treatment for similar employ, 57
Anderson, Maj. G. G., R.A.M.C. (see Obituary of the war)
Andrews, Mr. C. B., psychological aspect of 40 D, 342
Aneurysm, arterio-venous, 651
Angina pectoris (Lieut. G. Bousfield) 457
Anglo-Saxon medical journalism, Italian view, 400
Anomalous disease, 823
Anoxæmia (leading article), 634
Ante-natal and post-natal syphilis, treatment (Mr. J. Adams), 707, 770
Ante-natal care in the U.S.A., 656
Anthrax, prevention of (Py Q), 608
Anthropometry and national health, 542
"Antigens" in diagnosis by the Wassermann reaction, use of (Dr. C. H. Browning and Dr. E. L. Kennaway), 733
Antimony in bilharziosis, use of (Dr. J. B. Christopherson), 325, 371
Antineuritic and antiscorbutic factors in food, 52
Antiscorbutic principle, susceptibility to alkalinity (Prof. A. Harden and Dr. S. S. Zilva) 320; principle in limes and lemons (Dr. Harriette Chick and others), 735; (leading article), 751; value of raw juices of root vegetables (Dr. Harriette Chick and Mabel Rhodes), 774
Antityphoid sera, agglutinating properties of (Mr. T. T. O'Farrell), 626
Anuria, puerperal, 848
Anwyl-Davies, Dr. T., intramuscular administration of novarsenobillon, 757
Aphasia, concussion, treatment by general anæsthesia, 603
Apothecaries Society of London, pass lists, 27, 310, 537, 684, 760
Appeal tribunal on officers' disabilities (Py Q), 62
Appendicectomy, hæmatemesis as a complication (Dr. E. Drybrough-Smith), 15, 861
Applied Anatomy (Dr. G. G. Davies) fourth edition, 1918 (review), 746
Appointments, weekly list of, 65, 131, 161, 191, 224, 344, 375, 475, 541, 611, 654, 687, 764, 801, 863
Archibald, Dr. R. G., and Dr. J. B. Christopherson, primary nocardiasis of the lacrymal gland, 847
Archives de Médecine Navales (review), 330
Arkle, Dr. J. V., hæmatemesis as a complication of appendicectomy, 861
Armand-Delille, P., G. Paisseau, P. Abrami, and Henri Lemaire, Le Paludisme Macédonien, Principes de Thérapeutique (Malaria in Macedonia) (review), 208
Armistice and Parliament, 685
Armistices with Austria and Turkey, 652
Armour, Capt. R. S., R.A.M.C. (see Obituary of the war)
Army, medical needs of, and Ulster, 637
Army, prohibition order in regard to phenacetin and acetanilide, 256; service and medical women (Py Q), 687
Arsenic and Antimony, Organic Compounds of (Dr. G. T. Morgan) (review), 490
Art of Keeping Well (Dr. R. C. Macfie) (review), 209
Arthritis, rheumatoid, morbid anatomy and histology of, 628
Arthritis, septic, in gunshot wounds of knee-joint (Maj. A. Neve), 353; pneumococcus, vaccine treatment (Dr. C. E Campbell-Horsfall), 556; under phylacogen treatment, 651
"Arthrometer," 632
Artificial limbs provision of (Py Q), 25; Limbs (Prof. A. Broca and Dr. Duesquet (review), 79; limbs and surgical appliances (Py Q), 161; supply and adjustment, 401; for discharged soldiers (Py Q), 572, 653
Asclepios and Eshmun, 834
Asylum Officers' Superannuation Bill, 93
Asylum treatment of lunatic soldiers (Py Q), 223; strikes, 400
Athanassio-Benisty, Mme., Treatment and Repair of Nerve Lesions (review), 330; Clinical Forms of Nerve Lesions (review), 330
Atkin, Capt. K., R.A.M.C. (see Obituary of the war)
Atmospheric pollution, monthly record, 122, 216
"Atrophy, acute yellow" (?) (Capt. E. Glynn), 555, 590
Augwin dental emergency outfit, 574
Austen, Surg.-Com. T., R.N. (see Obituary of the war)
Autotherapy in influenza, 889

Aviation candidates, medical examination (Dr. G. A. Sutherland), 803; (leading article), 821
Aviators, successful and unsuccessful, essential characteristics of (Capt. T. S. Rippon), 411; strain and stress of flying (Lieut. E. G. Manuel), 415
Aviator's heart, 250

B

Baby week, lessons from (leading article), 18
Baccarani, Prof. U., meta-infective fevers, 20
Bacillary dysentery, outbreak (Lieut.-Col. G. S. Buchanan), 166
Bacilli, paratyphoid aad dysentery, capsulate and mucoid forms (Capt. W. Fletcher), 162, 183; dysentery, isolation from the fæces (Capt. H. Whitehead and Lance-Corporal J. Kirkpatrick), 143
Bacillus influenzæ and the present epidemic (Capt. T. R. Little, Capt. C. J. Garofalo, and Capt. P. A. Williams), 34; incidence of, in present epidemic (Dr. J. McIntosh), 695; *B. typhosus*, meningococcus, enterococcus and, isolation and cultivation of (Maj. J. Wilson and Dr. Georgina Darling, 105
Bacillus, Pfeiffer's, cultivation of, 91; preparing medium for (Dr. J. Matthews), 104
Bacteriology Clinical and Applied (Prof. R. T. Hewlett), sixth edition, 1918 (review), 47
Bacteriology of the prevailing paudemic, 123, 177
Bahr, Capt. P. H., and Capt. J. I. Enright, pyæmia due to organisms of the *Bacillus coli* group, 585
Baker, Surg.-Lieut. S. L., Mr. W. R. Thompson and Surg.-Lieut. Com. P. Fildes, pathology of present influenza epidemic, 697
Baldwin, Sir H., appointed surgeon-dentist to the King, 130
Banks, Mr. H. S., and Mr. B. Hughes, War Surgery from Firing Line to Base (review), 709
Banks-Davis, Dr. H. J., epithelioma of helix, 882
Bardswell, Dr. N. D., colonies for consumptives, 137
Barker, Dr. L. F., and Dr. R. Miller. perforating ulcer of hard palate in Vincent's disease, 598
Barlow, Mr. F. C., new rubber mask designed for general anæsthesia with ethyl chloride ampoules, 358
Barrett, Lady, retention of 40 D and allied subjects, 671
Barrett, Sir W., entoptic vision, 122
Barrow, Surg.-Lieut. R. M., treatment of influenza, 644
Bashford, Capt. E. F., Capt. J. T. Morrison, and Capt. J. N. J. Hartley, treatment of wounds, 230
Bassett, Lieut. R. J., R.A.M.C. (see Obituary of the war)
Bastian, Surg.-Com. W., influenza and the differential diagnosis of sandfly fever, 645
Batten, Dr. F. E., obituary, 157
Bayley, Surg.-Lieut. E., and Surg.-Lieut. A. G. Simmins, polio-encephalitis treated with novarsenobillon, 519
Bazy, Louis, what the war has taught us about tetanus, 523
Beale-Brown, Dr. T. R., West African M.S. (see Obituary of the war)
Becher, Dame Ethel, efficient teaching of nursing, 677
Beckwith, Surg. Prob. A. E., R.N.V.R. (see Obituary of the war)
Beer and scurvy (Mrs. A. H. Smith), 813; (leading article), 822
Begtrup-Hansen, Dr. Th., pulmonary tuberculosis and pregnancy, 334
Belfast, health of, in 1917, 336; serious condition, 466; influenza in, 795, 828
Belfast Royal Victoria Hospital, McQuitty Exhibition award, 61; Medical School, opening of winter session, 571
Belgian Doctors' and Pharmacists' Relief Fund (leading article), 17, 21, 55, 90, 121, 154, 174, 360, 427, 467, 533, 567, 601, 639, 672, 718, 825
Bell, Dr. J. H., reinstatement of, 114, 123; fund, 182, 222, 310, 375, 475, 571, 795
Bell, Mr. W. B., (1) Carcinoma corporis uteri, (2) carcinoma of Fallopian tubes, (3) hæmatometra in accessory uterine cavity, 572
Bell, Maj. A. S. G., and Miss I. M. Harmer, quick method of diagnosing meningococcus in cases of cerebro-spinal fever, 43, 125
Bence-Jones, albumosuria with lymphocytic leucocythæmia (Mr. H. L. Heimann and Mr. C. B. Wilson), 879
Benians, Mr. T. H. C., mucoid forms of paratyphoid bacilli, 182
Benjamin Rush, 889
Bhalaraksha, Lieut.-Col. H. S. (Nai Cheune), treatment of concussion aphasia by general anæsthesia, 603
Biernacki, Dr. J., obituary, 794
Bigger, Dr. J. W., and Capt. J. S. C. Douglas, loss of complementing power in kept serum, 44
Bilharziosis, antimony in (Dr. J. B. Christopherson), 325, 371
Billings, Dr. F., and Dr. B. O. Raulston, Practical Medicine Series (review), 359
Binet, M. Léon, and Prof. C. Achard, migration of metallic bodies in the circulatory current, 463
Binnie, Dr. J. F., Transactions of the American Surgical Association (review), 360
Births, Marriages, and Deaths, weekly lists of, 29, 65, 94, 131, 161, 191, 224, 250, 257, 344, 376, 409, 441, 475, 507, 541, 574, 611, 654, 687, 729, 764, 801, 833, 863, 898
Births, unrecorded, 828
Blackburn Medical Board (Py Q), 63
Blackwater fever and influenza (Dr. S. Samuel), 881
Blackwater fever (hæmoglobinuria) (Maj. L. G. Parsons and Capt. J. G. Forbes), 317
Bladder, urinary, total excision (Mr. J. C. Jefferson), 815
Blaker, Mr. W. C., nasal drill in the treatment of adenoids, 370
Bland-Sutton, Sir J., spolia opima, 594
Blood films and blood parasites, new methods of staining (Dr. L. Tribondeau), 142
Blood Pictures (Dr. C. Price-Jones) (review), 80; Pressure from the Clinical Standpoint (Dr. F. A Faught), second edition (review), 109; Pressure, its Clinical Applications (Dr. G. W. Norris), third edition, 1918 (review), 109; pressure measurements (Maj. E. S. Kilgore), 236; pressure and physical fitness of the soldier (Dr. V. E. Sorapure), 841
Blood, transfusion of, in war surgery (Maj. S. R. Harrison), 455
"Blow-hard," or methylated spirit, 656
Blue sclerotics (Dr. N. Voorhoeve), 740; (leading article), 751
Board of Education, report for 1917 of chief medical officer, 855, 891
Boils, Nile, and septic sores (Dr. H. W. Crowe), 667
Bombay, public health in, 729
Bond, Capt. C. W., R.A.M.C. (see Obituary of the war)
Bone, Prof. W. A., Coal and its Scientific Uses (review), 490
Bones, closure of cavities in, 817
Bonney, Dr. V., abdominal evacuation of pregnant uterus before viability, 518
Bonser, Capt. G. A. G., R.A.M.C. (see Obituary of the war)
Books, &c., received, 129, 161, 224, 256, 344, 409, 441, 540, 572, 611, 655, 800, 833
Books for reference, 766
Bordet, Dr., estimating augmentation in depth of volume of left ventricle, 750
Boro-chloretone in treatment of burns, 225, 258
Bost, Capt. T. C., new technique of heart disease, 552
Botulism, the real, 246; due to canned vegetables, 677
Boulenger, Dr. M. F., phthisis in factory and workshop, 829
Bousfield, Lieut. G., angina pectoris, 457
Box, Dr. C. R., apoplectiform variety of epidemic encephalitis, 723
Boycott, an enemy medical (leading article), 784
Boyd, Capt. J. T. W., Canadian A.M.C. (see Obituary of the war)
Boyd, Dr. J. St. C., death of, 197
Boyd, Lieut. T. M., R.A.M.C. (see Obituary of the war)
Bradley, Lieut.-Col. F. H., D.S.O., R.A.M.C. (see Obituary of the war)
Bradshaw lecture on neurosis and psychosis of war (Col. W. A. Turner), 613
Brain, extravasation of, after compound fracture of skull (Lieut. T. E. Coulson), 357
Brain surgery, war study of, 150; tumours, serological localisation of, 598
Bread, white, return to, 755; health *versus* custom, 788
Breast-feeding, faradisation of mammary glands (Dr. Elizabeth S. Chesser), 356
Breen, Maj T. F. P., R.A.M.C. (see Obituary of the war)
Brend, Dr. W. A., infant mortality and mothercraft, 124
Bridge, Dr. J C., skin diseases produced by lubricants, 464
Bridges, Lieut.-Col. R. H., D.S.O., R.A.M.C. (see Obituary of the war)
Briggs, Dr. H., placenta prævia, 572
Brindley, Dr. A. E., infant mortality and mothercraft, 341
Bristol Royal Infirmary, report, 61
Bristol University, pass lists, 92, 475
British aid to French wounded, 82; ambulance unit, first, for Italy, 720
British Columbia medical degrees (Py Q), 728
British Dentists' Hospital, report, 256
British Hospitals Association, conference, 566
British Journal of Children's Diseases (review), 209, 423
British Medical Association, meeting, 149
British Scientific Products Exhibition, 213, 247
Broca, Prof. A., and Dr. Ducroquet, Artificial Limbs (review), 79
Brock, Capt. G. S., I.M.S (see Obituary of the war)
Brock, Dr. J. H. E., trench fever in a civilian, 144
Bronchitis, spirochætal (Dr. H. Violle), 246; purulent, and influenza (Capt. A. Maude), 324; hæmorrhagic (Dr. H. Violle), 775
Broncho-pneumonia, purulent, associated with the meningococcus (Capt. J. A. Glover), 380
Brooke, Capt. F. A. J. R., R.A.M.C. (see Obituary of the war)
Brooks, Maj. H., and Maj. R. L. Cecil, unusual type of empyema, 636
Brown, Maj. W., treatment of shell shock, 197; hypnosis in hysteria, 433, 505
Browne, Dr. J. A., radical cure of very large hernia, 106
Browning, Dr. C. H., and Dr. E. L. Kennaway, use of "antigens" in diagnosis by the Wassermann reaction, 733
Brownson, Capt. R. D. D.-D., R.A.M.C. (see Obituary of the war)
Bubb, Mr. C. H., methods of control of fragments in gunshot wounds of jaw, 433
Buchanan, Lieut.-Col. G. S., outbreak of bacillary dysentery, 166
Buntine, Dr. R. A., death of, 571
Burckhardt-Socin, Dr. O., hormones in the climacteric, 714
Burns and scalds, shock in, 132
Burns and their Treatment (Dr. J. M. H. MacLeod) (review), 80; treatment of boro-chloretone, 225, 258
Burns, Capt. D., R.A.M.C. (see Obituary of the war)
Burns, Mr. John, medical man's income-tax, 531, 801
Burrows, Maj. D., R.A.M.C. (see Obituary of the war)
Bury, Maj. J. S., pathology of war neuroses, 97
Butcher, Mr. H. H., and Dr. A. J. Eagleton, treatment of influenza, 796
Butler, Dr. H. O., treatment of influenza, 796
Buttar, Dr. C., and Dr. A. Latham, election for the Scottish Universities, action of the Parliamentary Committee, 831
Buzzard, Dr. E. F., lethargic encephalitis, 835, 849

C

Cachexia, trench fever (Col. R. D. Rudolf), 809, 893
Cæcum, post-typhoid atony of (Prof. M. Loeper), 395
Cæsarean section three times in same patient (Mr. W. G. Spencer), 778
Cambell, Dr. A., new aero-urethroscope, 110
Cambridge Tuberculosis Colony, visit by the Queen, 539
Cambridge University, pass lists, 27, 570
Cameron, Dr. H. C., rickets and house infection, 646
Campbell, Capt. C. N. G., R.A.M.C. (see Obituary of the war)
Campbell, Capt. D., medical men in Parliament, 568
Campbell Capt. J., gunshot wounds of the joints, 477, 509
Campbell-Horsfall, Mr. C. E., pneumococcus arthritis, vaccine treatment, 556

CANADA, CORRESPONDENCE FROM.—Scientific and Industrial Council of Canada; Prescribing of liquor in Ontario; McGill University and the admission of women to the Faculty of Medicine, 179—Municipal hospitals in Western Canada; Child mortality in Montreal; Control of venereal diseases, 402—Sphagnum moss for surgical dressings; New dean of Laval University, Montreal, 403—Canadian voluntary war contributions; Canadian pensions; Casualties in the Canadian Expeditionary Force; Resolution passed at Hamilton medical meeting; Khaki University of Canada, 467

Canadian collection of medical war specimens, 215; voluntary war contributions, 467; pensions, 467; Expeditionary Force, casualties in, 467; soldiers and sailors, invalided, information for, 542
Canadian medical week in Hamilton, Ontario: Venereal disease; Child welfare; Tuberculosis; Problems of the returned soldier; Prevention of war neuroses; Broncho-pneumonia in Army camps; Delivery of addresses, 120—Resolutions passed, 467
Canadian Medical Week (review), 709
Cancer death-rate in Leicester, 345; research, local, 495

Cancer of the skin, contra-indications of radiotherapy in certain forms of, 786
Cantlie, Sir J., national tribute to voluntary ambulance workers, 795
Capsulate mucoid forms of paratyphoid and dysentery bacilli (Capt. W. Fletcher), 102
Carcinoma corporis uteri, 572; of Fallopian tubes, 572
Cardio-pathology, French, during the war (Ch. Laubry), 747
Carlill, Dr. Hildred, new reflex sign in spastic paraplegia, 254; home school wanted, 574
Carlyle, Surg. Sub-Lieut. T., R.N.V.R. (see Obituary of the war)
Carnegie endowment for international peace, 346
Carson, Maj. H. W., D.S.O., R.A.M.C. (see Obituary of the war)
Car-starting, easy, in cold weather, 656
Carter, Capt. H. R., infant mortality and mothercraft, 124
Carter, Dr. F. W., and Maj. H. M. Rashbrook, hypoadrenia simulating intestinal obstruction, 240
Carter, Dr. H. S., and others, Nutrition and Clinical Dietetics (review), 359
Carter, Mr. R. B., obituary, 607
Case-mortality of infectious diseases, 245
Castellani, Dr. A., tropical diseases in the Balkanic war zone, 889
Casting Out Fear (Mrs. F. B. Guest) (review), 886
Casualties in the war among the sons of medical men (see Casualties under War); in the Canadian Expeditionary Force, 467
Casualty lists of medical men (see Casualty lists under War)
Cataract, post-polar, 651
Catarrh, epidemic, our present knowledge of (leading article), 559
Catarrhs and influenza, epidemic (Sir A. Newsholme), 689
Cavendish lecture on development of the medical profession (Maj.-Gen. Sir B. Dawson), 51, 79, 83
Cecil, Maj. R. L., and Maj. H. Brooks, unusual type of empyema, 636
Centenarians, 226, 384, 797
Central Midwives Board, meeting, 27, 190, 538, 760; for Ireland, meeting, 507, 651; for Scotland, meeting, 862
Central surgeries in Battersea, 475
Centrifuge, an extemporised, 66
Cerebellar syndrome following heat-stroke, 561
Cerebro-spinal fever, nervous sequelæ (Capt. C. Worster-Drought), 39; meningococcus in, quick method of diagnosing (Maj. A. S. G. Bell and Miss I. M. Harmer), 43; naso-pharyngeal infection at the onset of, 217, 370, 404, 434, 567, 603; infection by a particular carrier (Capt. J. A. Glover), 422
Cerebro-spinal fluid in typhus, 532
Certificates, medical, prior to marriage and venereal diseases, 472
Certified occupations, 410
Chadwick lectures on the story of a new disease (Dr. F. G. Crookshank), 507
Chalmers, Dr. A. K., Dr. R. F. M. Picken, and Dr. A. MacLean, unusual forms of epidemic disease, 35
Chapple, Maj. W. A., re amputations, 105
Cheatle, Mr. A. H., risks of alcohol injection for trigeminal neuralgia, 56
Chemical Pathology (Dr. H. G. Wells), third edition, 1918 (review), 392; Analysis, Quantitative (Mr. F. Clowes and Mr. J. B. Coleman), eleventh edition, 1918 (review), 522
Chemical warfare, the medical side (leading article), 212
Chemistry, Applied Analytical, Treatise on (Prof. V. Villavecchia) (review), 672
Cherrett, Capt. B. W., East African Medical Force (see Obituary of the war)
Chesser, Dr. Elizabeth S., breast-feeding, faradisation of mammary glands, 356
Cheyne, Sir W. W., medical men in Parliament, 504
Chicago, sanitary instruction in, 563
Chick, Dr. Harriette and others, antiscorbutic principle in limes and lemons, 735; and Mabel Rhodes, antiscorbutic value of raw juices of root vegetables, 774
Childbirth, additional fuel in, 649
Child-welfare work and maternity (Sir A. Newsholme), 1; literature, 132; mortality in Montreal, 402; organisation work of, 884
Children's Jewel Fund, 730
Cholera situation in Europe, 113
Christmas (leading article), 853
Christopherson, Dr. J. B., use of antimony in bilharziosis, 325; and Dr. R. G. Archibald, primary nocardiasis of the lacrymal gland, 847
Civics and eugenics at Oxford, 256
Clark, Capt. R., R.A.M.C. (see Obituary of the war)
Clarke, Dr. E., Errors of Accommodation and Refraction of the Eye and their treatment, fourth edition, 1918 (review), 329
Clarkson, Mr. E. R. T., and Dr. A. M. Simpson, treatment of gonorrhœa, 731
"Clarocit," 210
Clavadel as a popular sanatorium, 30
Clayton, Capt. J. C., ether anæsthesia for face and jaw surgery, 454
Clerical, Medical, and General Life Assurance Society, report, 761
Climacteric, hormones in, 714
Clinical Diagnosis, a Manual of Laboratory Methods (Prof. J. C. Todd), fourth edition, 1918 (review), 588
Clinical medicine, study of (leading article), 259
Clippingdale, Dr. S. D., medical inventions, Dr. Gatling and the Gatling gun, 410; hereditary abnormality, 802
Clowes, Mr. F., and Mr. J. B. Coleman, Quantitative Chemical Analysis, eleventh edition, 1918 (review), 522
Coal and the cult of the skin (leading article), 331; and its Relation to Scientific Uses (Prof. W. A. Bone) (review), 490
Cocke, Capt. R. S., R.A.M.C. (see Obituary of the war)
Cockroaches, a short way with, 376
Codex Addendum, 1918, 310
Cœliac disease (Prof. G. F. Still), 163, 193, 227
Coffee perlettes, 16
Coleman, Mr. J. B., and Mr. F. Clowes, Quantitative Chemical Analysis, eleventh edition, 1918 (review), 522
Collier, Dr. W., new type of influenza, 567
Collins, Lieut.-Col. M. A., medical men in Parliament, 504
Collins, Lieut.-Col R. T., D.S.O., R.A.M.C. (see Obituary of the war)
Collins, Sir W. J., ophthalmology and the war, 122
Collosol cuprum, 16
Colonial health reports, 225, 258, 346, 612, 765, 834, 898
Colonial Medical Service, appointments, 297; and foreign medical degrees, registrable, 309
Colonies for consumptives (Dr. N. D. Bardswell), 137; and after-care, 343
Colonies in the treatment of pulmonary tuberculosis, 220
Colony treatment and after-care (Mr. P. C. Varrier-Jones and Col. G. S. Woodhead), 133
Colour in Relation to Chemical Constitution (Dr. E. R. Watson) (review), 490
Complement-fixation test in tuberculosis (Dr. E. Fidlar), 844, 853
Compton, Capt. A., treatment of staphylococcal infections by stannoxyl, 234
Compton, Capt. W. H., R.A.M.C. (see Obituary of the war)
Congress of Surgery, the coming, 249
Connolly, Capt. J. H., R.A.M.C. (see Obituary of the war)
Connor, Lieut.-Col. F. P., skin-grafting, 183
Consumption in Harvey's time and to-day, doctrine of (Dr. P. Kidd), 543, 582
Consumptives, colonies for (Dr. N. D. Bardswell), 137
Convoy, tale of a, 730
Cooking in military hospitals (Py Q) 608
Cookson, Maj. H. A., and Maj. M. G. Foster, small localised epidemic of influenza, 588
Cooper, Dr. J. S., death of, 312
Cooper, Mr. R. J., treatment of incipient mental disease, 679
Corbett, Lieut.-Col. C. D. H., Royal Air Force M.S. (see Obituary of the war)
Core, Capt. D. E., the "instinct-distortion," or "war neuroses," 168; hypnosis in hysteria, 471
Cornea, changes following inflammation, 670; observation of living nerve fibres, 714

CORRESPONDENTS, ANSWERS TO.—M.D. Durham, 30—R. B. A., 96—F. W. P., 132—J. S. McW., 226—W. H. K., M.D. O/C, 346—A. E. W., 376—D. M. S., 442—Practitioner, 574—Wullie, 730—Enquirer, Priority, 802

Cotterill, Capt. D., R.A.M.C. (see Obituary of the war)
Coulson, Lieut. T. E., recovery after compound fracture of skull with extravasation of brain, 357
Coulton, Mr. G. G., Social Life in Britain from the Conquest to the Reformation (review), 146
Courtois-Suffit, M., and M. R. Giroux, Abnormal Forms of Tetanus (review), 208
Cowie, Capt. G. R., South African M.C. (see Obituary of the war)
Cowper, Capt. G. M., R.A.M.C. (see Obituary of the war)
Cox, Dr. G. L., dispensary supervision in pulmonary tuberculosis, 757
Craig, Capt. C. M., and Maj. N. H. Fairley, typhus fever, 385
Craniotabes, clinical study of (Capt. E. Hughes), 36
Criminal Law Amendment Bill, 160
Cripples and beggars, 96
Critchett, Sir G. A., appointed surgeon-oculist in ordinary to the King, 375
Crofton, Dr. W. M., disappointments of vaccine therapy, 253
Crookshank, Dr. F. G., epidemic encephalitis, 57; the story of a new disease, 507; the "mysterious disease" in Australia, 1917, 645
Crotti, Dr. A., Thyroid and Thymus (review), 459
Crowe, Dr. H. W., septic sores and Nile boils, 667
Cruise, Mr. R. R., appointed surgeon-oculist extraordinary to the King, 375
Culham, Capt. H. A., Canadian A.M.C. (see Obituary of the war)
Cunningham, Prof. R. O., obituary, 157
Curwen, Miss K. M., Simple Experimental Hygiene, Physiology, and Infant Management for the Use of School Teachers (review), 746
Cushing, Prof. H., war study of brain surgery, 150; Tumours of the Nervus Acusticus and the Syndrome of the Cerebellopontile Angle (review), 391
Cyanamide and alcoholic drinks, 402
Cystoscopy and Urethroscopy, Treatise on (Dr. G. Luys) (review), 490

D

Dandridge, Lieut. W. L., R.A.M.C. (see Obituary of the war)
Daniels, Dr. C. W., and Dr. H. B. Newham, Laboratory Studies in Tropical Medicine, fourth edition, 1918 (review), 47
Darier, J., Précis de Dermatologie (review), 631; contra-indications of radiotherapy in certain forms of cancer of the skin, 786
Darling, Dr. Georgina, and Maj. W. J. Wilson, useful media for isolation and cultivation of meningococcus, enterococcus, and *B. typhosus*, 105
Davies, Dr. S., cancer research, 495
Davis, Dr. G. G., Applied Anatomy, fifth edition, 1918 (review), 746
Dawson, Maj.-Gen. Sir B., development of the medical profession, 51, 79, 83; spirochætosis icterohæmorrhagica, 575
Day, Prof. H. B., war nephritis, 660; or trench nephritis, 824
Deacon, Dr. Mary A. S., employment of pregnant women in munition factories, 311
Deafness, war (Dr. P. McBride and Dr. A. L. Turner), 73, 218, 253, 371
Deane, Brevet-Col. H. E., Gymnastic Treatment for Joint and Muscle Disabilities (review), 489
Death and invalidity in Australia, causes of, 335; and Correlated Aspects of Life in Art, Epigram, and Poetry (Dr. F. P. Weber), third edition, 1918 (review), 489
Death, sudden, after an anæsthetic (Maj. P. Turner), 384
Decease, rapid, in young men (Maj. A. Abrahams and Dr. N. F. Hallows), 239
Decorations, foreign (see Decorations under War)
Decortication of kidney for post-eclamptic suppression of urine, 572
Delphinium poisoning, 96
Demetriadi, Lieut.-Col. L. P., R.A.M.C. (see Obituary of the war)
Demobilisation and venereal diseases (leading article), 783, 823
Demobilisation, medical, 683, 722
Dental and medical professions, numerical position, 308; treatment of discharged soldiers (Py Q), 685; caries, causes and incidence, 861
Dentists in the army (Py Q), 160; registered, position of, 310
Departed Things, History of (Mrs. Henry Head) (review), 47
Dermatology (Précis de Dermatologie), (J. Darier), (review), 631
Derry, Mr. B. G., death of, 220
Desfosses, M. P., and M. Robert, La Suspension dans le Traitement des Fractures (review), 359
Despatches, mentioned in (see Despatches under War)
Devaux, Dr., cerebro-spinal fluid in typhus, 532
Devon and Cornwall Sanatorium for Consumptives, Didworthy, report, 819
Devon Insurance Committee, report, 375
Devonport Royal Albert Hospital, meeting, 832
Diabetes, modern views on (Dr. E. P. Poulton), 31; (leading article), 49
Diabetic Manual for Mutual Use of Doctor and Patient (Dr. E. P. Joslin) (review), 490
Diaries for 1919, 802
Dick, Dr. J. L., abnormal conditions of enamel in case of malnutrition, 456
Dickson, Capt. E. C., the real botulism, 246; botulism due to canned vegetables, 677
Dictionary, medical (Dr. W. B. Drummond) (review), 146; Short Italian (Dr. A. Hoare) (review), 146

Diet, influence on teeth formation (Mrs. May Mellanby), 767
Dietetics: Special rations for invalids; Extra rations for nursing and expectant mothers, 121; Rations in other expectant cases, 122
Disabled man, future of the, 399; care of, 765
Disabled Officers' Home and Club, seaside branch at Frinton, 898
Disease, an anomalous, 823
Disease, epidemic, unusual forms (Dr. A. K. Chalmers, Dr. R. M. F. Picken, and Dr. A. MacLean), 35; polio-encephalitis and, of obscure origin (Dr. R. M. F. Picken), 35; acute febrile (Dr. A. MacLean), 36; new, the story of (Dr. F. G. Crookshank), 507; inheritance and acquirement of, a study of the rejected, 744
Diseases, prevalent in domestic animals, 656
Diseases, the names of (leading article), 332
Disinfection and prevention of lice-borne diseases (Col. W. Hunter), 347, 377
Disinfection of public vehicles in Calcutta, 132; nasal, 647
Dislocation of both hip-joints, 651
Disodo-luargol in treatment of malaria (Capt. W. A. Murray and Mr. R. W. H. Row), 355
Dispensary doctors, salaries of, 466
Dispensary supervision in pulmonary tuberculosis (Dr. G. Jessel), 564, 597, 68[illegible]756, 830, 894
Dispensatory of the United States of America (Mr. J. P. Remington and Dr. H. C. Wood, jun.), twentieth edition, 1918 (review), 146
Doctor, woman, how to become a, 310
Doctors, women, whole-time, in the Army (Py Q), 26; women, dearth of, 761
Dold, Capt. C. L., R.A.M.C. (see Obituary of the war)
Donaldson, Capt. J., R.A.M.C. (see Obituary of the war)
Donaldson, Dr. R., influenza and preventive inoculation, 603; etiology of influenza, 722
Donations and bequests, 92, 127, 158, 187, 191, 233, 353, 539, 570, 680, 726, 825, 857
Donkin, Sir H. B., "sexual perversion," 56; prevention of venereal infection, 342; prophylaxis of venereal diseases, 505
Dorgan, Maj. J., naso-pharyngeal infection at the onset of cerebro-spinal fever, 217
Douglas, Capt. J. S. C., and Dr. J. W. Bigger, loss of complementing power in kept serum, 44
Dow, Lieut. J., I.M.S. (see Obituary of the war)
Downie, Capt. J. M., R.A.M.C. (see Obituary of the war)
Doyen, Dr. E., Surgical Therapeutics and Operative Technique (review), 522
Drage, Dr. L., juries and war-time changes, 56
Dried milk (Ambrosia brand), 210; *versus* condensed milk, 245; *v.* condensed milk, a correction, 433
"Drop-foot" support, 192
Drowning, resuscitation from, 30, 66
Drug-supply after four years of war (leading article), 243
Drug idiosyncrasy, 472
Drugs, expensive, and insured patients, 57; botanic, and herb-growing, 345
Drummond, Dr. W. B., Medical Dictionary (review), 146
Drummond, Dr. J. C., antineuritic and antiscorbutic factors in food, 52; some aspects of infant feeding, 482
Drybrough Smith, Dr. E., hæmatemesis as a complication of appendicectomy, 15
Dual professions, the, 442
Dublin University, Trinity College, School of Physic, pass lists, 92; Parliamentary representation of, 757
Dudley, Staff-Surg. S. F., acute lymphocythæmia, 183
Ducroquet, Dr., and Prof. A. Broca, Artificial Limbs (review), 79
Duffy, Capt. J. V., R.A.M.C. (see Obituary of the war)
Duggan, Maj. C. W., R.A.M.C. (see Obituary of the war)
Dunlop, Capt. H., Canadian A.M.C. (see Obituary of the war)
Dunn, Maj. W. E. N., causes and incidence of dental caries, 861
Dunne, Dr. A. B., medical certificates prior to marriage and venereal diseases, 472
Durham University, Faculty of Medicine, pass lists, 27, 475
Duval, Pierre, War Wounds of the Lung (review), 359
Dyke, Capt. H. W., outbreak of scurvy in the South African Native Labour Corps, 513
Dyke, Capt. S. C., prognosis in "trench" nephritis, 320
Dysenteries, the, differential diagnosis (Capt. J. G. Willmore and Capt. C. H. Shearman), 200
Dysentery and paratyphoid bacilli, capsulate mucoid forms of (Capt. W. Fletcher), 102
Dysentery bacilli, isolation of, from the fæces (Capt. H. Whitehead and Lance-Corporal J. Kirkpatrick), 143; bacillary, outbreak (Lieut.-Col. G. S. Buchanan), 166; amœbic and bacillary, macroscopic and microscopic methods of diagnosing (Capt. J. G. Thomson and Capt. L. F. Hirst), 448; bacilli isolated, types of (Capt. J. G. Thomson and Capt. L. F. Hirst), 449; amœbic (Capt. J. G. Thomson), 451; amœbic, examinations for, 724

E

Eager, Maj. R., year's work at a mental section, 177
Eagleton, Dr. A. J., and Mr. H. H. Butcher, treatment of influenza, 796
Ear, Internal, Enquire into its Analytical Mechanism (Sir T. Wrightson) (review), 46
East African campaign, medical service in, 221
Eccles, Maj. M. (1) arterio-venous aneurysm, (2) fibrosarcoma of thigh, (3) a "foot-hand," 651
Ectopic gestation, 572
Education, natural science in (Prof. E. H. Starling), 365
Egg "substitutes," 225
Eggonine and its derivatives, 51
Egypt, public health reform, 599; medical association for, 611; public health in, 715
Electricity, Medical (Dr. H. L. Jones) (review), 522
Electrolysis in Chemical Industry, Applications of (Mr. A. J. Hale) (review), 490
Elliott, Mr. A. B., acute œdema of the lungs, 24
Ellis, Dr. H. A., dispensary supervision in pulmonary tuberculosis, 756
Ellis, Mrs. H., James Hinton (review), 850
Elmes, Capt. K., R.A.M.C. (see Obituary of the war)
Elsie Inglis London Memorial Fund, 503; chair of medicine, 797
Embarkation and boat distribution scheme, combined (Maj. H. Hemsted), 382
Emergency substitutes, call for, 156
Emergency Surgery (Dr. J. W. Stuss), fourth edition (review), 745
Emery, Capt. W. d'Este, standardisation of the Wassermann reaction, 547
Empyema technique, new, 335; unusual type, 636
Empyemas, local anæsthesia for (Dr. C. W. Morris and Dr. L. Horsley), 880
Encephalitis epidemic (Dr. S. A. K. Wilson), 7, 57, 91, 848; lethargic (Dr. A. J. Rice-Oxley), 15, 557, 590, 635, 837, 849, 888; acute (Lieut. W. B. Russell), 106; lethargica, 557, 590; epidemic, apoplectiform variety, 723
"Encephalitis, obscure epidemic" (Mr. S. K. Vaidya), 322
Enemy medical boycott (leading article), 784
Enright, Capt. J. I., and Capt. P. H. Bahr, pyæmia due to organisms of the *Bacillus coli* group, 585
Enright, Capt. W. J., Canadian A.M.C. (see Obituary of the war)
Enteric fevers, microbic diversity of (Prof. C. Achard), 393; fever in Flanders in 1914-1915, 881
Enteritis, fatal, in rabbits, 508
Entoptic vision, 122
Epithelioma of helix, 882
Epsom College, meeting, 23; Royal Medical Foundation, 787; appeal, 795
Ergoestesiograph, the (Prof. G. Galeotti), 702
Ether Day in London, Oct. 16th, 562
Ether in the operating theatre, risks of, 258; anæsthesia for face and jaw surgery (Capt. J. C. Clayton), 454
Euthanasia, 508
Evans, Dr. H. M., treatment of scurvy, 864
Evans, Mr. A., the late Richard Grainger Hebb, 153
Evatmine, 672
Ewart, Dr. W., nasal drill in the treatment of adenoids, 370
Examining Board in England of the Royal Colleges of Physicians of London and Surgeons of England, pass lists, 190
Exemption, a question of, 221; for medical practitioners, 503
Exophthalmic goitre, local anæsthesia and twilight sleep in (Mr. S. H. Rouquette), 776
Eye, war injuries of (Col. W. T. Lister), 67; in War, Fractures of the Orbit and Injuries to (Prof. F. Lagrange) (review), 79; Errors of Accommodation and Refraction and their Treatment (Dr. E. Clarke), fourth edition, 1918 (review), 329; Diseases of (Mr. J. H. Parsons), third edition, 1918 (review), 782; Ear, Nose, and Throat (Practical Medicine Series) (review), 782
Eye spud, new, 632
Eyre, Dr. J. W. H., and Capt. C. E. Lowe, prophylactic vaccinations, 484

F

Face and jaw surgery, ether anæsthesia for (Capt. J. C. Clayton), 454
Facial operations (Mr. R. Lake), 354
Facial surgery, general anæsthesia in, 56, 125
Factory and workshop conditions of pulmonary phthisis (Prof. B. Moore), 618
Faichnie, Lieut.-Col. N., notification of indigenous malaria, 648
Fairbairn, Dr. J. S., Text-book for Midwives, second edition, 1918 (review), 631
Fairley, Maj. N. H., and Capt. C. M. Craig, typhus fever, 385
Falconer's arthrometer, 766
Falmouth, Viscountess, Passing On of Life (review), 632
Family, the, how to feed, 573
Faught, Dr. F. A., Blood Pressure from the Clinical Standpoint, second edition (review), 109
Fazakerley Sanatorium (Py Q), 572
Febrile disease, acute (Dr. A. MacLean), 36
Feeding, artificial, prolonged (Dr. J. B. Tuke), 458
Fees, maternity, in East Riding, 226
Female Pelvic Viscera, Studies of (Dr. R. H. Paramore) (review), 671
Femur, gunshot fractures of (Maj. P. Turner), 74; fractures of (Capt. P. L. W. Williams), 452
Ferguson, Mr. J., Thyrea and Other Sonnets (review), 423
Fermentose, 672
Ferrier, Sir D., and others, case of Dr. J. H. Bell, 123
Fevers, meta-infective, 20
Fibro-sarcoma of thigh, 651
Fibroids and Allied Tumours (Myoma and Adenomyoma (Dr. C. Lockyer) (review), 885
Fidlar, Dr. E., complement-fixation test in tuberculosis, 844
Fifth year of war (leading article), 111
Fildes, Staff-Surg. P., naso-pharyngeal infection at the onset of cerebro spinal fever, 370, 567; Surg.-Lieut. S. L. Baker, and Mr. W. R. Thompson, pathology of present influenza epidemic, 697
Filling up the ranks (leading article), 462
Finch, Capt. G., R.A.M.C. (see Obituary of the war)
Findlay, Surg. G. M., occurrence of *Spirochæta eurygyrata* in man, 114
Fingland, Mr. W., death of, 217
Fire precautions, simple, for the coming winter, 470, 730
First-aid in ordinary life, 755
Fischel, Capt. C. H., R.A.M.C. (see Obituary of the war)
Fleming, Mr. C. E. S., management of lunacy patients, 473; treatment of incipient mental disease, 679
Fletcher, Capt. W., capsulate mucoid forms of paratyphoid and dysentery bacilli, 102; quinine resistant malaria, 432
Fletcher, Sir W. M., influenza epidemic, 643
Flying, strain and stress of (Lieut. E. G. Manuel), 415; officer, successful, attributes of (leading article) 425
Fly-quit products 210
Folk-medicine in the Aran Islands, 66
"Food and how to save it," 399
Food, antineuritic and antiscorbutic factors in, 52, 647; and scurvy, memorandum by the Food (War) Committee of the Royal Society, 756; health and the General Election, 801; factor 802

Raymond, Prof., tetanus consecutive to superficial wounds and trench foot, treatment and prevention, 526

French Supplement to THE LANCET (leading article), 398
Frew, Capt. J. W., R.A.M.C. (see Obituary of the war)
Fruit-stones for war purposes, use of, 66
Fuel economy, 766

G

Gage, Capt. J. M., R.A.M.C. (see Obituary of the war)
Gairdner, Dr. J., manganese poisoning, 434
Galeotti, Prof. G., the ergoestesiograph, 702
Gangrene, gas, preventive and curative serum for, 178; serum-therapy of, 249; pathology of, discussion, 816
Gangrene of lung, treatment by induction of pneumothorax, 753
Gardiner, Mr. H., treatment of extensive septic wounds, 777
Gardner, Mr. H. B., nasal drill in treatment of adenoids, 434
Garnett, Maj. W. S., Australian A.M.C. (see Obituary of the war)
Garofalo, Capt. C. J., Capt. P. A. Williams, and Capt. T. R. Little, *B. influenzæ* and the present epidemic, 34
Garrett, Lieut. D. G. K., R.A.M.C (see Obituary of the war)
Gas, exhaust, poisoning from, 494
Gas gangrene, preventive and curative serum for, 178; serum-therapy of, 249; (La Gangrène gazeuse) (Prof. Weinberg and Dr. P. Séguin) (review), 329; pathology of, discussion, 816
Gas-oxygen, gas-oxygen-ether, and warmed-ether apparatus, combined, 48
Gassed patients, treatment, 402
Gaston, Capt. J., M.C., R.A.M.C. (see Obituary of the war)
Gauvain, Mr. H. J., tuberculous disease of hip-joint, 666
Gauze, paraffined, 495
Gavronsky, the Abderhalden reaction, 830
Gear, Surg. Sub-Lieut. J. D., R.N.V.R. (see Obituary of the war)
General Board of Control for Scotland, fourth annual report, 181
General Council of Medical Education and Registration of the United Kingdom, powers, duties, and constitution, 262, 831

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION (WINTER SESSION).—Presidential address; Effects of the war and reconstruction; Ministry of Health and other legislative measures; Examination in general education; Training in preventive medicine, 762—Appointment of officers, 763—Registration of Canadian medical qualifications; Case of Jules Michael Ralph Flament; Case of Thos. Stoney Sharpley, 797—Case of Isaac Bernard Barclay; Case of Stanley Henry; Case of John Stanley Francis; "Army education certificate" in general education; Case of Dr. J. M. R. Flament, 798—Case of Frederick Charles Beamont; Apothecaries' Hall of Ireland, appendix to report, 826—Report of Education Committee on nature of recognition to be extended to schools examinations recently established by the Board of Education; Report of Pharmacopœia Committee; Ministry of Public Health; Dental education and examination, 827

German civilian health, 853
German, Maj. H. B., M.C., R.A.M.C. (see Obituary of the war)
Germinated beans in treatment of scurvy (Dr. H. W. Wiltshire), 811
Gigantism of right index and middle finger, 651
Gillett, Dr. H. T., influenza and preventive inoculation, 643
Giroux, M. R., and M. Courtois-Suffit, Abnormal Forms of Tetanus (review), 208
Gittens, Mr. C. W., staphylococcus phlebitis, 488
Gland, lacrymal, primary nocardiasis of (Dr. J. B. Christopherson and Dr. R. G. Archibald), 847
Glascott, Dr. C. E., death of, 360
Glasgow University, pass-lists, 27, 130, 507; Mr. R. T. Leiper awarded the Bellahouston gold medal, 28
Glassware, national importance of, 787
Glenny, Lieut. E. H., R.A.M.C. (see Obituary of the war)
Gley, Prof. E., The Internal Secretions, their Physiology and Application to Pathology (review) 360
Glottis, œdema of, in rheumatic fever, 82
Glover, Capt. J. A., cerebro-spinal fever, infection by a particular carrier, 422; purulent broncho-pneumonia associated with the meningococcus, 880
Glycerine for medicinal purposes (Py Q), 26
Glynn, Capt. E., "acute yellow atrophy" (?), 555, 590
Godlee, Sir R. J., national tribute to voluntary ambulance workers, 795
Goitre, simple, prevention by administration of iodine, 214; exophthalmic, local anæsthesia and twilight sleep in (Mr. S. H. Rouquette), 776
Gonococcus antigen, new method of preparing (Capt. D. Thomson), 42
Gonorrhœa, treatment (Mr. E. R. T. Clarkson and Dr. A. M. Simpson), 731
Gonorrhœa, Treatment of (Capt. N. P. L. Lumb) (review), 47
Goodall, Dr. E. W., enteric fever in Flanders in 1914–1915, 881
Gordon, Dr. W., future of the medical profession, 153; distantly audible heart sounds, 458
Gordon, Lieut.-Col. M. H., naso-pharyngeal infection at the onset of cerebro-spinal fever, 218, 404, 603
Gosse, Miss Teresa, and Countess Selborne, Elsie Inglis chair of medicine, 797
Gould, Sir A. P., War Emergency Fund of the R.M.B.F., 537
Goulstonian lectures on modern views of diabetes (Dr. E. P. Poulton), 31
Grading, medical, at Bristol (Py Q), 25; and examinations, 25; under the new Military Service Act (Py Q), 62; new, of older men (Py Q), 63; medical (Py Q), 63, 130; medical practitioners and an appeal against, 91; medical, of older men, 127
Graham, Capt. T. F., Canadian A.M.C. (see Obituary of the war)
Grant, Dr. A. G. M., skin lesions during tuberculin treatment, 15
Grant, Mr. J. W. G., malignant disease of upper extremity, 700
Grant, Mr. M., Passing of the Great Race (review), 632
Graves, Prof. W. P., Gynecology, second edition, 1918 (review), 820
Gray, Mr. H., Anatomy, Descriptive and Applied, twentieth edition, 1918 (review), 709
Gray, Mr. H. T., (1) gigantism of right index and middle finger, (2) congenital dislocation of both hip-joints, 651
Green, Capt. P. S., R.A.M.C. (see Obituary of the war)
Greenaway, Mr. T. S., drug idiosyncrasy, 472
Greenwood, Capt. M., influenza epidemic, 643
Griffith, Dr. A. H., obituary, 537
Grimbly, the late Mr. R. H., memorial to, 225
Guarini, Dr. C., small heart in tuberculous subjects, 214
Guest, Mrs. F. B., Casting out Fear, (review) 886
Guides to medical service at the front, 30
Guilfoyle, Capt. T. R., Canadian A.M.C. (see Obituary of the war)
Gumma of entire left lung (Capt. R. Hall), 779
Gunewardene, Dr. T. H., acute poliomyelitis in an infant 12 days old, 847
Gunshot fractures of femur (Maj. P. Turner) 74; wounds of peripheral nerves (Maj. C. Noon) 100; wounds of thorax (Dr. J. A. Wilson) 102; wounds of the jaws, fragments in (Maj. H. P. Pickerill) 313, 433, 474; wounds of the knee-joint with septic arthritis (Maj. A. Neve) 353; wounds (Maj. J. J. M. Shaw) 390; injuries of peripheral nerves, pathological diagnosis in (Dr. J. S. B. Stopford) 445
Gunshot wounds of the joints (Capt. J. Campbell), 477, 509; (leading article) 527
Gunzburg's test, 125
Guy's Hospital Medical School, scholarship awards, 475; Medical Research Fellowship, 710
Gyllencreutz, Capt. J. R., R.A.M.C. (see Obituary of the war)
Gymnastic Treatment for Joint and Muscle Disabilities (Brevet-Col. H. E. Deane) (review) 489
Gynæcology, spinal analgesia in, routine use (Dr. N. Mahfouz Bey) 141, 150; Clinical (Dr. J. C. Wood) (review) 460
Gynecology (Prof. W. P. Graves), second edition, 1918 (review) 820

H

Hadwen, Surg. Lieut.-Com. J., R.N. (see Obituary of the war)
Haegert, Dr. J. F., heliotherapy in Africa, 429
Hæmatemesis as a complication of appendicectomy (Dr. E. Drybrough-Smith), 15, 861
Hæmatometra in accessory uterine cavity, 572
Hæmoglobinuria (blackwater fever) (Maj. L. G. Parsons and Capt. J. G. Forbes), 317
Hæmoptysis, recurrent, due to gunshot wounds of the chest, 402
Hæmorrhage of toxæmic origin, 572
Hæmorrhagic bronchitis (Dr. H. Violle), 775
Hale, Capt. W. F., Canadian A.M.C. (see Obituary of the war)
Hale, Mr. A. J., Applications of Electrolysis in Chemical Industry (review), 490
Halford, Miss J., additional fuel in childbirth, 649
Hall, Capt. R., gumma of entire left lung, 779
Hall, Prof. A. J., notification of indigenous malaria, 505
Hallows, Dr. N. F., and Maj. A. Abrahams, rapid decease in young men, 239
Hamilton, Capt. C. D., Canadian A.M.C. (see Obituary of the war)
Hamilton, Dr. J., death of, 470
Hann, Maj. R. G., acute pneumonia followed by pneumothorax, 519
Hanson, Mr. W. C., and Dr. G. M. Kober, Diseases of Occupation and Vocational Hygiene (review), 242
Harden, Prof. A., and Dr. S. S. Zilva, anti-neuritic and antiscorbutic factors in food, 52; susceptibility of the antiscorbutic principle to alkalinity, 320
Harman, Mr. B., (1) detached retina, (2) post-polar cataract, 651; new eye spud, 632
Harmer, Miss I. M., and Maj. A. S. G. Bell, quick method of diagnosing meningococcus in cases of cerebro-spinal fever, 43, 125
Harris, Dr. D. T., the recent influenza epidemic, 877
Harrison, Brevet-Col. L. W., portable "606" outfit, 710
Harrison, Capt. F. C., R.A.M.C. (see Obituary of the war)
Harrison, Lieut.-Col. E. F., C.M.G., obituary, 681
Harrison, Lieut.-Col. L. W., D.S.O., public health problems under war and after-war conditions, 655
Harrison, Maj. S. R., transfusion of blood in war surgery, 455
Harrison, Maj. S. S. B., M.C., R.A.M.C. (see Obituary of the war)
Harrisson, Mr. D., death of, 345 (also see Obituary of the war)
Hart, Dr. B., Modern Treatment of Mental and Nervous Disorders (review), 391
Hartley, Capt. J. N. J., Capt. E. F. Bashford, and Capt. J. T. Morrison, treatment of wounds, 230
Hartzell, Prof. M. H., Diseases of the Skin (review), 671
Harveian Oration on the doctrine of consumption in Harvey's time and to-day (Dr. P. Kidd), 543, 582
Harvey and the place of pathology in medicine, 252
Hay, Capt. W. S. B., R.A.M.C. (see Obituary of the war)
Hay fever outfit, 210
Head, Dr. H., some principles of neurology, 657
Head, Mrs. Henry, History of Departed Things (review), 47
Heald, Lieut. W. M., R.A.M.C. (see Obituary of the war)
Health and education, 635
Health centre, a model, 463
Health reports, colonial, 225, 258, 346, 612, 765, 834, 898
Health resorts of the British Islands, 125
Heart-beat, Clinical Disorders of (Dr. T. L. Lewis), fourth edition (review), 107

Heart Disease and Uræmia (Mr. E. P. Poulton), 32; Diseases of (Dr. F. W. Price) (review), 107
Heart disease, new technique (Capt. T. C. Bost), 552
Heart, small, in tuberculous subjects, 214; aviators', 250; sounds, distantly audible (Dr. W. Gordon), 458; beat, repeated cessation (Dr. G. P. Poulton and Dr. H. M. Stewart), 738
Heat-stroke, cerebellar syndrome following, 561
Hebb, Dr. R. G., the late, 153
Hebrew University at Jerusalem, creation of, significance to medicine, 192
Heimann, Mr. H. L., and Mr. C. B. Wilson, Bence-Jones's albumosuria with lymphocytic leucocythæmia, 879
Heliotherapy in Africa, 429
Hemiplegia, transient (Dr. H. H. Mills), 145, 149, 254; due to tuberculous meningitis, 178
Hemsted, Maj. H., combined embarkation and boat distribution scheme, 382
Herbert, Dr. S., Introduction to the Physiology and Psychology of Sex (review), 359
Herb-growing and botanic drugs, 345
Hereditary abnormality, 802
Hernia, very large, radical cure (Dr. J. A. Browne), 106; inguinal, very large, radical cure (Surg. C. P. G. Wakeley), 357; inguinal, strangulated, with external rupture of sac (Dr. H. E. Renton), 358
Herringham, Maj.-Gen. Sir W. P., medical men in Parliament, 537; London University election, a protest, 831
Hewlett, Prof. R. T., Manual of Bacteriology, Clinical and Applied, sixth edition, 1918 (review), 47
Higgens, Mr. C., triplex glass, 95
Hill, Dr. H. B., influenza, or a new disease, 645
Hill, Dr. L., phthisis in factory and workshop, 680
Hind, Dr. Clara, death of, 474
Hine, Maj. T. G. M., "trypagar," 154; nasopharyngeal infection at the onset of cerebrospinal fever, 434
Hip-joint, tuberculous disease (Mr. H. J. Gauvain), 666
Hirsch, Capt. C. T. W., gas-oxygen, gas-oxygen-ether and warmed-ether apparatus, combined, 48
Hirst, Capt. L. F., and Capt. J. G. Thomson, macroscopic and microscopic methods of diagnosing amœbic and bacillary dysentery, 448; types of dysentery bacilli isolated, 449
Hitchcock, Dr. C. W. H., poisoning from exhaust gas, 494
Hoare, Dr. A., Short Italian Dictionary (review), 146
Hodgson, Capt. A. E., quick diagnosis in meningococcus infection, 91
Hodgson, Lieut.-Col. J. E., R.A.M.C. (see Obituary of the war)
Holden, Dr. O., dispensary supervision in pulmonary tuberculosis, 830
Home Nursing (review), 886
Home school wanted, 574
Honours, 215; war (see Honours under War)
Horder, Sir T., influenza and preventive inoculation, 642; general principles in treatment of influenza, 694, 796; severe cases of influenza, 871
Hormones in the climacteric, 714
Horsley, Dr. L., and Dr. C. W. Morris, local anæsthesia for empyemas, 880
Hospital ships and ambulance transports, combined embarkation and boat distribution scheme for (Maj. H. Hemsted), 382; economies, 864
Hospital Sunday Fund, Metropolitan, 26, 72, 223, 891; at Bristol, 353
Hospitals in France (Py Q), 160; municipal, in Western Canada, 402

Nerve Lesions, Treatment and Repair (Mme. Athanassio-Benisty) (review), 330; Clinical Forms of (Mme. Athanassio-Benisty) (review), 330
Nerve strain, treatment of (Py Q), 131
Nerves, peripheral, gunshot wounds of (Maj. C. Noon), 100; peripheral, gunshot injuries of, pathological diagnosis in (Dr. J. S. B. Stopford), 445
Nervous Diseases, Introduction to the Study and Treatment of (Locomotor Ataxia) (Dr. W. J. M. A. Maloney) (review), 241
Nervous sequelæ of cerebro-spinal fever (Capt. C. Worster-Drought), 39; disorders, functional, in the Army, treatment, 82, 153; disorders, reflex (Maj. J. S. Bury), 97
Nervous System, Diseases of, a Text-book of Neurology and Psychiatry (Dr. S. E. Jelliffe and Dr. W. A. White), second edition, 1918 (review), 241
Nervous systems, sympathetic and central, interdependence of, 494, 883
Netter, M. Arnold, and M. Marius Mozer, meningococci purpura without meningitis, 530
Neuralgia, trigeminal, operative treatment (Prof. J. Hutchinson), 12; risks of alcohol injection, 56
Neurasthenia, prevention and treatment, 160; infective factors in, 160
Neurasthenic and hysterical cases in general military hospitals (Dr. R. H. Trotter), 703
Neurology, some principles of (Dr. H. Head), 657, 676, 725
Neuroses, war, pathology of (Maj. J. S. Bury), 97; war, treatment, 219, 341, 370; war, systematic instruction in, 335; and psychoses of war (Col. W. A. Turner), 613
Neve, Maj. A., gunshot wounds of the knee-joint with septic arthritis, 353
Névros thénine (Freyssinge), 672
"New" Disease, story of, 602
Newham, Dr. H. B., and Dr. C. W. Daniels, Laboratory Studies in Tropical Medicine, fourth edition, 1918 (review), 47

NEW INVENTIONS—
Aero-urethroscope, new, 110
"Arthrometer," 632
Eye spud, new, 632
Gas-oxygen, gas-oxygen-ether, and warmed-ether apparatus, combined, 48
Laryngotome and tracheotome, new, 746
Mask, new rubber, designed for general anæsthesia with ethyl-chloride ampoules, 358
Mon-aural stethoscope, improved, 110
Portable "606" outfit, 710
"Screw-stand" for use in bone-plating, 210

Newsholme, Sir A., maternity and child-welfare work, 1; incidence of infectious disease in 1917, 52; epidemic catarrhs and influenza, 689
New Town after the War (review), 208
Newton, Capt. E., R.A.M.C. (see Obituary of the war)
Nias, Dr. J. B., Dr. John Radcliffe, a Sketch of his Life (review), 781
Nicoll, Capt. M., reconstruction in neurology, 724
Nile boils and septic sores (Dr. H. W. Crowe), 667
"No blind people, but only normal people who cannot see," 30
No cardiasis, primary, of the lacrymal gland (Dr. J. B. Christopherson and Dr. R. G. Archibald), 847
Noon, Maj. C., gunshot wounds of peripheral nerves, 100
Norris, Dr. G. W., Blood Pressure, its Clinical Applications, third edition, 1918 (review), 109
North London Medical and Chirurgical Society (see Medical Societies)
North of England Obstetrical and Gynecological Society (see Medical Societies)
Nose, hygiene of, 854

NOTES AND SHORT COMMENTS.—"No blind people, but only normal people who cannot see"; Resuscitation from drowning, 30, 66—American poison plants; Clavadel as a popular sanatorium; Guides to medical service at the front; Rockefeller Foundation, 30—Folk-medicine in the Aran Islands; An extemporised centrifuge; Use of fruit-stones for war purposes, 66—Triplex glass, 95—Cripples and beggars; Secondary resection of injured joints; Albumin reaction in sputum; Thermometer for the blind; Rats and plague; Delphinium poisoning; Improved novarsenobenzol preparations and apparatus; Franco American surgical appliances, 96—Shock in burns and scalds; Medicine in Spanish; Child-welfare literature; Disinfection of public vehicles in Calcutta; More moulting, 132—Metropolitan water-supply during January, February, and March, 1918; Deaths from influenza; Cost of war-time prescriptions; Red Cross at sea, 162—Significance to medicine of creation of Hebrew University at Jerusalem; Vitamines and cooking; Occupations for women; Parasitic mange; "Drop-foot" support; Necessitous Ladies' Holiday Fund; Overworked medical man, 192—Colonial health reports, 225, 258, 346, 612, 765, 834, 898—Borochloretone in treatment of burns, 225, 258—Memorial to the late Mr. R. H. Grimbly; Egg "substitute," 225—Some medical notes

from ancient Mesopotamia; "Vitamogen"; Household economy; Triplex glass; Maternity fees in East Riding; Somerset centenarians, 226—Household Fuel and Lighting Order; Treatment of influenza in Switzerland; Risks of ether in the Operating theatre, 258—New Indian qualifications; How to become a woman doctor; Position of registered dentists; Veterinary surgeons and National Service, 310—Herb-growing and botanic drugs; Medical men and the volunteer obligation; Care of the foot, 345—Condition of service and pay of Special Reserve, R.A.M.C.; Carnegie endowment for international peace; Specific paraplegia in cattle and horses; Useful field incinerator, 346—Forgotten physician of the second century; Short way with cockroaches, 376—"Toy" kinematographs; Mediæval medical author, 410, 612—Metropolitan water-supply during April, May, and June, 1918; Certified occupations; Physician's technique; Medical inventions, Dr. Gatling and the Gatling gun, 410—"Our Day"; Dual professions; 40 D; Threatened strike in an asylum; End of summer time, 442—Ratan Tata Foundation for social science; Paraffin therapy; Zeebrugge Mole, 476—Cases of solanine poisoning; John of Burgundy; Euthanasia; Fatal enteritis in rabbits, 508—Some early British surgeons; Anthropometry and national health; Information for invalided Canadian soldiers and sailors, 542—Racial reconstruction and the proposed Ministry of Health; How to feed the family; Public eulogy of the medical professor, 573—Augwin dental emergency outfit; Accurate clinical thermometry; Home school wanted, 574—Work of the London Port Sanitary Authority; Royal Albert Institution for Defectives, Lancaster; Prevention of venereal, 612—Menace of venereal disease, 655—Royal Earlswood Institution for Mental Defectives; Pioneer of infant welfare; Easy car-starting in cold weather; Paying patients and the West of England Eye Infirmary, Exeter; Antenatal care in the U.S.A.; Prevalent diseases in domestic animals; "Blow-hard," or methylated spirits, 656—Influenza disinfection and the rôle of the carrier; Institute of Hygiene; Lebanon Hospital for Mental Diseases; Medical man's income-tax, 688—Tuberculous soldier; Public health in Bombay, 729—Tale of a convoy; Children's Jewel Fund; Precautions against fire, 730—Care of the disabled; Lamet, 765—Women and a Ministry of Health; Precautions against influenza in French schools; Books for reference; Minor surgery in the forecastle; Intramuscular injection of mercuric chloride in influenza; Fuel economy; Royal Institution, Christmas course of juvenile lectures; Falconer's arthrometer, 766 — Food, health, and the General Election; Medical man's income-tax, 801—"Dr. Wise on influenza"; Diaries for 1919; Medical profession and the petrol restrictions; Wanted, a home; Hereditary abnormality; Food factor; Present epidemic and the pressure on practitioners; Menace of the murinæ; Nutrient media in the shop, 802—Asclepios and Eshmun; "Wellcome" Photographic Exposure Record, 1919; Weston-super-Mare Hospital, 834—Organisation work of child welfare; Unauthorised; Hospital economies; "Abdulla" Almanack, 1919; Treatment of scurvy; Plague dispensaries, 864—"Limpet" system of electrodes; Disabled Officers' Home and Club, seaside branch at Frinton, 898

Notice, brought to (see Notice under war)
Novarsenobenzol preparations and apparatus, improved, 96
Novarsenobillon, intramuscular administration of, 757
Numerical position of the medical and dental professions, 308
Nurses, registration of, 20, 82; Army, training of (Py Q), 161; shortage of, 325; nation's tribute to, 554
Nursing, efficient teaching of, 677
Nursing home tragedy, 863
Nutrient media in the shop, 802
Nutrition and Clinical Dietetics (Dr. H. Carter and others) (review), 359

END OF THE SECOND VOLUME FOR 1918.

PRINTED and PUBLISHED by the PROPRIETORS, WAKLEY AND SON (1912), LTD., at No. 423, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London.

An Address
ON
SOME ASPECTS OF
MATERNITY AND CHILD-WELFARE WORK.

Delivered before a Conference of County and Local Sanitary Authorities of the County of Durham on June 22nd, 1918,

BY ARTHUR NEWSHOLME, K.C.B., M.D.,
MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD.

MR. CHAIRMAN AND GENTLEMEN,—Conferences of sanitary authorities like this which you have asked me to address give valuable opportunity to exchange experience and programmes for extended work; and, as representing the department of the Government which is chiefly concerned in stimulating maternity and child welfare work, and—to use a recent phrase of Mr. Hayes Fisher—in "fertilising it by grants," I welcome the opportunity of setting forth some general considerations on the subject and of learning from the local experience of members of the Conference.

INFANTILE MORTALITY IN DURHAM.

Although this may be tedious to those who fail to appreciate the value of a quantitative statement of experience, let me first indicate to you how Durham stands in regard to infant mortality, with which, I need hardly remind you, is associated on a much larger scale even more serious loss of local and national health and efficiency. And, in order that we may begin on a hopeful note, let me first state the improvement in the administrative county of Durham as compared with the average experience of England and Wales and of New Zealand, a happy country whose white population has been planted within the memory of living man, and which has no evil inheritance from the eighteenth and nineteenth centuries of crowded towns, of huddled industrial villages, and of slum areas.

TABLE I.—*Average Infant Mortality per 1000 Births.*

—	Administrative County of Durham.	England and Wales.	New Zealand.
1896–1900	169	156	80
1911–1915	134	110	53
Percentage improvement in 15 years ...	21%	30%	33%

Although the figures in Table I. give encouragement they show a less favourable record for England and Wales and still less so for the county of Durham than for New Zealand, as the possibilities of reducing a high death-rate are much greater than when, as in New Zealand, the death-rate has been relatively low throughout. It is evident that much work needs to be done before we can reach the favoured position occupied by New Zealand. The fact that in counties such as Oxfordshire the infant death-rate in 1915 was 70, and in Berkshire and Herts 71, while in an industrial town like Coventry it was as low as 89 per 1000 births, and that in areas such as these the death-rate continues to decline, shows that the task before us is not insuperable.

Unsatisfactory Position of Durham.

So much for the past. The picture of Durham's position when compared with the current average experience of England and Wales is less satisfactory. In this average experience is included that of counties occupying, like Lancashire, Glamorganshire, Staffordshire, and Northumberland, of which the best that can be said is that their position is not quite so unfavourable as that of Durham: and were these counties excluded from the comparison, the terrible position of Durham in regard to infant mortality would be more fully revealed.

Confining ourselves, however, to the comparison with England and Wales as a whole, and considering only the figures given in the last six annual reports of the Registrar-General, the excess of loss of infant life in the county of Durham is shown in Table II.

TABLE II.—*Geographical County of Durham: Aggregate Experience of Six Years, 1911–16.*

—	Total deaths under 1 year of age.	These deaths were in excess of the number that would have occurred had infants in Durham shared the average experience of England and Wales by—	Percentage excess.
Administrative county (excluding Darlington)	21,648	4,181	24
Darlington	981	2	—
Gateshead	2,813	553	25
South Shields	2,563	422	20
Sunderland	3 712	761	26
West Hartlepool	1,331	171	15
Entire geographical county...	33,048	6,090	—

That is, on an average 1000 deaths of infants have occurred every year in the geographical county of Durham which would have been avoided had Durham shared the only mediocre experience of England and Wales as a whole, or that of the town of Darlington within its own borders. I leave it to the medical officers of health of each constituent part of the county to explain to you in detail that this excessive mortality is much greater in some than in other parts of the county, and to remind you that no inhabitant of a district, either in Durham or elsewhere, which enjoys a relatively low infant mortality will be able to say that there are not within its borders "pockets"—streets or areas—which are unnecessary death-traps for infants living in them, and in which intensive child-welfare work is not able still further to reduce infant mortality, and the even more serious sickness of infancy and consequential adult inefficiency.

Causes of Excessive Infant Mortality in Durham.

I do not propose to pursue further my comparisons for each of the county boroughs, but for the administrative county let me state the following additional facts showing some of the more potent causes of excessive infant mortality (Table III.):—

TABLE III.—*Administrative County of Durham: Experience of Six Years 1911–16.*

—	Total deaths under 1 year of age.	These deaths were in excess of the number that would have occurred had infants in Durham shared the average experience of England and Wales by—	Percentage excess.
Congenital debility, &c.	7635	1661	28
Diarrhœa	5476	3452	172
Pneumonia	2028	265	15
Bronchitis	1812	477	36
Whooping-cough... ...	758	107	17
Measles	567	125	28

Evidently the causes of death included under the first heading above (including congenital malformation, premature birth, infantile debility, and marasmus, &c.), and which usually end fatally within a month of birth, are largely accountable for the excess. Bronchitis and pneumonia are also excessive; but diarrhœa is the most important disease, the combating of which will secure the largest saving of child life.

INSANITARY CONDITIONS CALLING FOR REFORM.

It is necessary that I should relate this excessive diarrhœal mortality with the excessive prevalence of enteric fever in Durham. Dr. Wheaton's report on enteric fever in Durham, published by the Local Government Board in 1911, still deserves perusal; and I have to state that recent experience of enteric fever, although greatly improved, shows that in Durham the risk of acquiring and of dying from enteric fever is still twice or three times as great as for England and Wales as a whole. Putting it on the lowest basis, past experience of this disease represents a serious financial loss to the county—in wages, in cost of medical attendances and nursing, in cost of funeral expenses, and in loss of accrued economic

value of individual lives, which for the whole county on a low estimate must have exceeded half a million sterling annually; and if to this be added the cost of excessive infant mortality and sickness this sum will easily be doubled. If this money were spent on essential sanitary reforms in every village and town in the county, and if with this was associated an active awakening to the parallel need for improved personal hygiene, there is no sufficient reason why the infant mortality in the county of Durham should not fall rapidly below the present average rate for England and Wales.

Before I pass from this part of my subject let me enumerate the worst features of insanitation still prevailing, though in less degree than in the past, in some of the densely populated mining villages and towns of Durham. These comprise unpaved and undrained streets and back yards, imperfection of scavenging and excrement removal, privies persisting where water-closets are practicable; all implying the blowing into the dwelling of dry excremental spillings and deposits, and their conveyance indoors by flies and on the feet and hands of children and adults. I ask the medical officers of health here present whether the statement in my preface to the report already quoted was not justifiable that the extremely filthy domestic arrangements by which excremental matters are retained in the immediate neighbourhood of dwellings are "deplorable insanitary conditions urgently calling for reform."

Housing Accommodation.

If I do not mention in detail the unsatisfactory housing in a large part of mining Durham, it must not be assumed that I underrate the importance of improvement in this respect. Durham and Northumberland have the worst housing in the country. In Durham, out of every 100 total dwellings at the last Census, 22 were found to comprise only two rooms as compared with 8·3 for England and Wales, and 27 of three rooms as compared with 14 for England and Wales; and the proportion per cent. of the total population living overcrowded, in the sense that there were more than two persons to a room, was 28·5 in the county as compared with 9·1 for England and Wales as a whole. It is legitimate cause for surprise that organised miners have not hitherto insisted on better housing conditions, and required, even though this implies higher rents, a minimum of sanitation and housing for their wives and children. Such a minimum standard would insist on domestic conditions now too seldom secured by miners earning high wages. Meanwhile the wives of miners and their families, who constitute by far the largest proportion of the total population of Durham, suffer in health from the inability or unwillingness of the miners to release themselves from the degraded housing conditions associated with the "free" houses of inferior quality commonly supplied by colliery owners, and from the defects of municipal sanitation the continuance of which it is well within their power to prevent. Could any of us secure a more favourable record of sickness and death for our children than holds good for the families of a large proportion of wage-earners in Durham and elsewhere if our houses had no larder for food, no sink, or a sink without hot water-supply over it, if the backyard and front and back street were unpaved, and if a malodorous ashpit and privy were in the near vicinity of the dwelling? Before we lay chief stress on ignorance and carelessness, it is our duty to ensure, so far as our individual power goes, that the local council and the landlord of the house are supplying the rudimentary needs of sanitary living.

It is the lack of these elementary requirements that is largely responsible for the excessive diarrhœal mortality and the excessive mortality from bronchitis and pneumonia in the county of Durham; and I have shown elsewhere that it bears no inconsiderable part also in causing excess in the death-toll during the first month or two after birth.[1]

RELATIONS OF SANITATION AND PERSONAL HYGIENE.

I have thought it necessary to set out at some length a statement of the insanitary conditions, on the remedying of which depends largely the success of efforts at personal hygiene. This does not mean that the efforts to promote personal hygiene—the struggle towards personal and domestic cleanliness (almost in the surgical sense) which this implies—will not, even under adverse circumstances, succeed in improving the prospect of healthy childhood. The possibilities of such success are, however, multiplied manifold when the minimum conditions of municipal and domestic sanitation are fulfilled; and it is in this connexion particularly that the medical officers of health and sanitary inspectors of each of the urban and rural authorities within the county of Durham can render possible a rapid improvement in child hygiene.

This is not the only channel in which combined district and county work should run. There is always risk, but avoidable risk, when two sets of authorities are concerned in a given task that one or other will lose interest in it. In the county boroughs this difficulty does not arise; and in the administrative county of Durham, with a county medical officer of health of supreme ability and possessed of great tact and judgment, its possibility is minimised; but there is often reason to regret that district and county activity in child-welfare work is not more equally developed and balanced throughout the country and that district and county authorities are not in more regular and systematic coöperation than at present. There is good reason for allowing the county council to arrange health visiting and to organise nursing facilities for districts with a population below 20,000; but the prevention and treatment of infectious diseases, including enteric fever, diarrhœa, and measles, the promotion of domestic cleanliness and sanitation, the improvement of housing conditions, rest chiefly on the district staff, and it is only when district and county medical officers of health, sanitary inspectors, and health visitors actively coöperate—and, may I add, when county and district councils abandon any latent or open antagonism—that rapid success in saving child life can be ensured.

WELFARE WORK.

The achievement of the sanitary minimum of healthy family life, then, depends in the first instance on municipal and district sanitation and reasonably good housing. This implies, as I have already suggested, convenient and labour-saving arrangements for personal and domestic cleanliness and for the storage of food.

"Home-helps."

The next great need is domestic assistance for the wife or mother, when without this her own or her children's health are likely to suffer. With this object in view the Board have decided to extend the scope of their 50 per cent. grants by including the provision of "home-helps" in suitable cases during the lying-in period. The avoidance of over-fatigue and anxiety at this period is essential, and the assistance of neighbours is not always available. The Board similarly are encouraging experiments in paying for the maintenance away from home of the older children during the same period. This is in addition to the already available grants of one-half of the cost of provision by the local authority of the cost of a midwife, or of a doctor called in to assist the midwife, or of a maternity nurse.

The Organisation of Nursing Facilities.

I have already referred to the excessive mortality from diarrhœa and from measles and whooping-cough in Durham. Even when measures to prevent attack have failed, measures to prevent death from an attack may succeed, and this branch of public health work until recently has been almost completely unexplored so far as domiciliary treatment is concerned.

I hope that very shortly public opinion everywhere will require sanitary authorities to provide nurses for every case of sickness needing it. For the above-named diseases, for ophthalmia neonatorum, and for illness connected with pregnancy and parturition, half the cost of nursing provided by or on behalf of the local authorities will be refunded by the Local Government Board. Sanitary authorities need not, however, stop at these diseases, but can, with the Board's sanction, provide home nursing for the poorer inhabitants of their districts in other cases under the powers given by Sec. 133 of the Public Health Act, 1875. Skilled nursing in illness is one of the most efficient means of relieving the over-burdened mother. In measles experience in many areas is already showing its high value in the saving of life, and I trust that through the county or district nursing associations or otherwise this will ere long be organised in Durham.

Until recently the county of Durham has had no county, and but few district, nursing associations, and thus in respect of the organisation of nursing facilities has been in a less favourable position than any county having a similar population. The proposals for the provision of such a service constitute a great step forward in local sanitary efficiency, and I hope that ere long a fully organised service of county and district nursing associations will be in a position to provide in Durham midwives and maternity nurses where required, working in close association with the councils of the county and county boroughs.

Health Visitors.

A service of health visitors is indispensable in securing a good standard of domestic hygiene, and it is unnecessary that I should enlarge on this branch of work, which is already developing in Durham, both in the administrative county and the five county boroughs, with one exception, on the advice of the active and progressive medical officers of health of these boroughs. I may, however, draw attention to the fact that although the Board—in view of the need for home visitation up to school age—has considered that there should be one health visitor to 400 births, the proportion in the

[1] Page 38, First Report on Infant and Child Mortality, Cd. 5263.

geographical county as a whole is only 1 to 1100 births. Gateshead still has not started on this essential work, and in West Hartlepool and South Shields there is only the equivalent of one health visitor to 1500 or 1600 births. The administrative county has the equivalent of one whole-time health visitor to about 1100 births.

Maternity Homes: Child Welfare.

One result of bad housing conditions in Durham is that confinement has to take place in a house which commonly has only one bedroom, or at most two. A partial remedy for this is better housing; but even when this is available, in many cases the mother does not secure at home as good a prospect of healthy recovery as in a maternity home. The Board's grants are available for such homes; and I look forward to the time when each area will have such a home, ensuring for the mother and the newly-born infant who need this assistance the best possible start in their next year's joint life.

In addition to child welfare centres with adequate antenatal and infant consultations the Board's grants are now available also for hospitals for children under 5, not including ordinary infectious diseases, but including epidemic diarrhœa; and for creches provided by local authorities, for convalescent homes after confinement, and for children after recovery from illness. Even more important, the Board are now able to promise grants for the maintenance of the infants of widowed, deserted, or unmarried mothers along with their infants in special homes or otherwise. The object of the last-named grant is the moral and hygienic gain both to the mother and infant which can only be secured by keeping them together.

I may add that one item of the new regulations of the Board promises grants for "experimental work for the health of expectant and nursing mothers and of children under 5 years of age carried out by local authorities or voluntary agencies with the approval of the Board." This sufficiently shows the desire of the Board to aid progress by local experimentation on promising lines, and I trust that both local authorities and voluntary agencies will share in such experimental as in the general work of child-welfare.

Voluntary Efforts.

It will be a misfortune if local authorities lose the assistance of non-official voluntary agencies. There is need to bring every influence to bear, and to interest all social workers in the cause in order that the best results may be obtained. There is no valid ground for contrasting official and voluntary work as regards efficiency and sympathy. Either or both of these may be perfunctory, irregular, incomplete, and lacking in insight; and both of them happily often display the opposite qualities. If the way for one is not open the other should be adopted; and voluntary beginnings have repeatedly shown the way to municipal effort on a larger scale.

AN APPEAL TO THE PUBLIC CONSCIENCE.

To act helpfully we must know thoroughly the conditions and causes which have hitherto been producing excessive sickness among mothers and children. No member of a local authority in Durham can now plead ignorance when called to render his account for evil conditions and avoidable sickness and deaths due to the default of his colleagues and himself. The reports of the local and the county medical officers of health, of Government officials, and now the statements in this address make clear the responsibility of district and county councillors and of owners of property. They make equally clear the duty of husbands and fathers to arrange that their wives and children receive more adequate and better medical, nursing, and domestic assistance than is now secured, and to insist on obtaining and being willing to pay the rental of better houses. All this will cost money. But sickness costs more money; the industrial and social inefficiency of adults resulting from illness in childhood costs still more money. Health, when we have paid for it, is always cheaper than disease; and within limits we can have as much health as we are prepared to pay for.

We should be prepared to do this, not merely or chiefly because it is economically sound, but because we are our brother's keeper; we are members one of another. "It is not the will of your Father that one of these little ones should perish." But at least 1000, in reality many more, infants perish unnecessarily every year in the county of Durham. How soon will the indifference of a majority of local councillors, of the general public, and of parents themselves be broken down, and the public conscience call for the easily attainable cessation of the present Herodian sacrifice of child life?

QUEEN'S UNIVERSITY OF BELFAST.—A correspondent writes: "Arrangements are being made for the appointment of a professor of anatomy in place of Dr. J. Symington, resigned. The salary will be £1000, with a retiring pension. The results of the summer matriculation, published last week, show that out of 310 candidates 75 passed. Such an extraordinarily large percentage of rejections indicates either (*a*) an unusually high university standard, or (*b*) poor school teaching, or (*c*) an inferior type of students. The matter is naturally being much discussed."

INFANT MORTALITY AND THE EDUCATION OF THE MOTHER:

A CRITICISM OF THE REPORT OF THE MEDICAL RESEARCH COMMITTEE.

BY H. W. POOLER, M.B. BIRM.,

MEDICAL OFFICER TO INFANT WELFARE CENTRES, DERBYSHIRE COUNTY COUNCIL.

THE report of Dr. W. A. Brend and Dr. Leonard Findlay to the Medical Research Committee of the National Insurance Commission, issued in August, 1917,[1] is one that should have most careful consideration from all interesting themselves in saving infant life, and particularly from those engaged in one of the principal phases of that work, the education of the mother, whether by means of house-to-house visiting or through the agency of infant consultations, schools for mothers, baby welcomes, and the like.

Main Conclusions of Report.

Findlay, by means of a chart of infant mortality in England, Scotland, and Ireland dating back to 1864, attempts to show that the fall in mortality in the last 20 years is independent of the educational methods of about the same period, and as a matter of fact began before those methods could have had any influence at all.

Brend compares the infant mortality of typical agricultural districts with that of the large towns. He shows, first, that the mortality in the first month after birth (about one-third of the whole) is practically the same in two such districts, and is due to ante-natal causes, of which at present we have little knowledge, but which are equally operative in both town and country. He next points out that after the first month the mortality amongst infants is mainly a question of post-natal environment. By a process of exclusion of possible causes common to both town and country life he finally arrives at the conclusion that the one cause operating in the large towns and not existing in the country is pollution of atmosphere by dust and smoke, mainly, as one infers, from smoke.

By this route he arrives at the same conclusion as Findlay—viz., that educational methods are only touching the fringe of the question and are of quite small importance compared with the clearing of slum areas and the abatement of smoke pollution.

Some Authoritative Views.

That the acceptance of this theory means nothing short of a revolution in our conception of infant welfare work can be judged from three quotations, out of many possible, from the writings of eminent authorities. Sir George Newman says:—

> "The environment of the infant is its mother; its health and physical fitness are dependent primarily upon her health, her capacity in domesticity, and her knowledge of infant care and management."[2]

Concerning the excessive mortality amongst infants in slum areas the Report of the Interdepartmental Committee on Physical Deterioration states:—

> "We shall not perhaps be far from the mark if in judging of the evil effects of bad housing and of poor social conditions we give chief place to the laziness, want of thrift, ignorance of household management, and particularly of the choice and preparation of food, filth, indifference to parental obligations, and drunkenness which largely infect adults of both sexes and press with terrible severity upon their children."[3]

Lastly, the President of the Third International Congress on Infant Mortality in Berlin, 1911, Professor Dietrich, writes in the Handbook to the Congress:—

> "The most effective means of instruction, *according to the unanimous opinion of all experts*, are the stations for the care of infants, after the model of the Infants Consultations ..... 'Welfare' stations take the first place, *according to German experience, among the practical measures adopted for the protection of child life.*"[4]

The Campaign against Infant Mortality.

As a consequence of the general consensus of opinion typified in the above extracts an enormous and increasing amount of work has been undertaken in the last 20 years, all, whatever its outward shape, having for its guiding principle the education of the mother and the improvement of the home.

House-to-house visitation by experts and voluntary visitors has become the rule in almost every town and county in the kingdom; infant welfare centres, infant consultations, schools for mothers, baby welcomes, *et hoc genus omne*, have been established in practically

every district in England and Wales in which infant mortality can be said to be in excess. Many thousands of pounds annually are being spent on this work from Government, county, municipal, and philanthropic sources, and enormous voluntary and paid effort is being put forth.

At the time of writing I have before me a record of close on 300 public authorities which are carrying on infant consultations and the like, and a further list of nearly 600 philanthropic societies doing a similar work; and this in England and Wales only. As many of these authorities or societies have more than one centre it is probably a modest estimate to say that there are now at least 1200 centres with a clientèle of well over 150,000 children.

Is all this to be incontinently scrapped? If the suggestions of Brend and Findlay are founded on a firm basis, that is the question which we have to ask ourselves. If their chain of reasoning is strong in every link and their conclusions unassailable, a review of our position and a radical change in our theories and methods are inevitable.

But are they so unassailable? I venture to think that the facts on which their argument is based, and the processes by which they arrive at their conclusions are singularly weak in certain directions, and by no means so convincing as under the circumstances we have a right to expect.

Influence of Educational Measures.

Take, for instance, Findlay's Chart No. 1, showing the infant mortality for England, Scotland, and Ireland from 1864 to 1914. Having pointed out how the variations on this chart singularly correspond in each country in each year and that a general decline set in about the year 1900, Findlay deduces from this that the special educational measures adopted in England can have had but little influence, since similar methods have been hardly begun even yet in Ireland, which shares, however, in the general improvement.

I can hardly understand such a deduction being legitimately drawn from this chart. With the exception of 1880 and the period from 1891 to 1900 the infant mortality in Ireland has hardly varied from its original level of 95 per 1000 in 1864, and certainly since 1900 there has been no such rapid and consistent fall as that of the English rate. In 1914 the Irish rate was 19 per cent. below that of 1900, while in England and Wales it was 31 per cent. below 1900.

In a recent address to the Royal Academy of Medicine in Ireland Sir W. Thompson, Registrar-General, stated that, comparing the periods 1866–70 and 1911–15 infant mortality in Ireland had fallen 4 per cent., in Scotland 7 per cent., and in England and Wales 30 per cent.[5]

A striking feature of these curves is that right away to 1908 the Scottish rate was consistently and often considerably lower than the English rate; since 1908, with the exception of the year 1911 with a very hot summer, the English rate has been actually lower than the Scottish rate. I think it is safe to say that in the last 10 or 12 years much greater strides have been made in educational infant welfare work in England than in Scotland.

Incidentally Findlay's chart can hardly be considered as supporting Brend's theory as to the preponderating influence of smoke pollution. It can hardly be contended that there has been sufficient abatement of that evil in the last 20 years to account for the great improvement in the infant death-rate.

But Findlay further points out that the improvement manifested since 1900 began something like 10 years before educational methods were sufficiently universal to have made much impression. Here, I confess, he is on stronger ground. Apparently, however, he has overlooked the fact that an integral portion of the educational campaign is the training in housekeeping and baby management of the school-girl. Educational work of this type has been going on for 20 years, and has been pretty general in this country for at least 10 years. Is it unreasonable to ascribe some portion of the improvement, at any rate, to this phase of the campaign?

Comparative Poverty in Town and Country.

And now let us briefly review Dr. Brend's argument also. As I have indicated, he compares the infant mortality in certain county boroughs of the north and in the rural districts of the south. Having enumerated the causes of excessive infant mortality as given by Newsholme, he arrives, by a process of exclusion, at the conclusion that the one outstanding cause of mortality not common to town and country is the atmospheric pollution, mainly by smoke, existing in the urban areas.

But his process of exclusion is, I think, open to very grave criticism, and many people will disagree with the dogmatic statements he makes. Take, for instance, his assertions as to the comparative poverty of the urban and rural labourers. He says (p. 8) that the wages of the agricultural labourer are the lowest paid in the community, that the influence of poverty is felt most directly in *housing and food-supply*, and that it is impossible to say that in these respects rural districts are better off than towns.

On this question of the comparative poverty of the town and country labourer we have little exact information. What we have to compare is the wage of the rural labourer and that of the unskilled and casual worker of the town slums, for it is amongst the latter class that the real excess of infant deaths takes place, and not amongst the skilled and respectable artisans of the better type of working-class neighbourhoods. Now, from my own personal experience as a countryman born and bred, who has spent most of his working years in a great town, I have no hesitation in stating that the average country labourer *and his family* are infinitely better off than the slum dweller and his dependents.

Wages and Domestic Economy.

It is not the gross wage that matters; it is in the first place the net amount that reaches the housekeeper, and, in the second place, *the use made of it*. Within certain limits, a comparatively low but regular weekly wage is better for the children than a variable or casual wage averaging a higher amount.

Working at a large infant consultation in a slum district of Birmingham for many years, I have observed over and over again that the infant of the low-waged but regularly paid railway goods porter or shunter was a better nourished and healthier child than that of the equally but less regularly paid unskilled or casual labourer, market porter, or the like. It is the irregular wage, not the low wage, again within limits, that makes housekeeping difficult and ultimately demoralises the housewife. Not that I maintain that low wages is not bad for the child; the exact opposite is the case, as I have shown elsewhere.[6 7]

Dr. E. W. Hope, medical officer of health of Liverpool, has quite recently said:—

> "The household is the ultimate agency of distribution of economic wealth to individuals; what the wage-earner secures and the wife and children secure depends upon the efficiency of the use made of the income by the household. The home can be, in fact usually is, responsible for malnutrition and insanitary living, notwithstanding that liberal wages may be earned, from want of appreciation or knowledge of the relative values in or methods of the preparation of foods or wasteful expenditure in valueless things—for example, alcohol. Too few women of the working-class households have sufficient knowledge to enable them to meet ordinary domestic demands."[8]

It is in matters of these kinds that the family of the low-waged agricultural labourer is better off than the families of the slum-dwellers of the towns, or even than those of the comparatively high-waged, if less regularly waged, miner.

Absence of Real Poverty in Rural Areas.

But apart from the *use* of wages, is the family of the labourer dwelling in those parts of a town where excess mortality is rife really better off financially than the agricultural family? While in Birmingham I carefully inquired into the financial means of all the women attending my consultation*—nearly 2000 in all.

> I found that in the years before the war 68·5 per cent. of these women were in poverty, according to Rowntree's well-known standard, and 41 per cent. of the families had an average weekly income of 1s 7d. per person after rent was paid. Only 31·5 per cent. were not in poverty, and this although Rowntree's scale was by no means high and allowed for the "barest necessities for physical efficiency." And this without gardens, pigs, poultry, and all the little extra perquisites which help on the rural labourer so much.

Can any rural district be compared financially with such an area? In her summary of the report of the Royal Commission on the Poor-law Mrs. Bosanquet, dealing with pauperism and poverty in rural areas, writes of—

> "The almost unvarying evidence we have received to the effect that *in country districts there is little or no real poverty.*"[9]

That, for some reason or other, there is much malnutrition amongst the mothers of the working classes in large towns is certain. I have known repeated cases of nursing mothers denying themselves essential food in order that their elder children might not go lacking. Dr. Duncan, late one of the medical officers for infant welfare work in Birmingham, states in one of her reports:—

> "I have paid many unexpected visits to their homes and have found that many of the women were only having tea and bread and lard for breakfast and supper. In some cases the diet was even poorer."[10]

* The infant mortality in these families = 203; and in the ward generally for the five years ending 1910 = 205.

These were women who were being provided with dinners from philanthropic sources. Dr. Brend himself recognises this fact in his statements on p. 12 of his report when he writes:—

"As a class town mothers are less healthy and well nourished than country mothers"; ..... "general malnutrition and poor physical development are widespread among mothers in the poorer parts of the towns."

Influence of Income on Weight of Infant.

That poverty, in its restricted primary sense of low income, has a very direct influence on even the breast-fed child I am convinced. I have shown elsewhere [6 7] that from three months onwards the breast-fed child in poverty is smaller than the breast-fed child not in poverty, and I here reproduce some of the tables on which I based this conclusion.

TABLE I.—*Shows Average Weights of Infants at Various Periods. Infants Grouped According to Poverty and Irrespective of Mode of Feeding.*

Group A (1)—641 families with less than 2*s.* 6*d.* per person.
,, (2)—431 families with 2*s.* 6*d.* or over per person.
Group B—493 families over Rowntree's Poverty Line.

—	Average number in family.	Average income per person, less rent.	Average weight of infants. At 3 weeks.	13 weeks.	26 weeks.	39 weeks.	52 weeks.
			lb. oz.	lb. oz.	lb. oz	lb. oz.	lb. oz.
Group A (1)	6·13	1*s.* 7*d.*	8 1	10 9	12 1	15 11¼	17 1
,, (2)	5·1	2*s.* 11¼*d.*	8 3	10 10	13 14	15 12½	17 8
Group B ...	3·68	4*s.* 11½*d.*	7 15½	11 1½	14 5	16 11	18 11

TABLE II.—*Showing Average Weights at One Year of Infants Grouped According to Average Weekly Income of Individual Members of Family After Rent is Paid.*

	Income up to— 1*s.*	2*s.*	3*s.*	4*s.*	5*s.*	Over 5*s.*
	lb. oz.	lb. oz.	lb. oz.	lb. oz.	lb. oz.	lb. oz.
Entirely breast-fed to six months	17 13	18 0	18 13	18 7	18 12½	20 2½
Not entirely breast-fed to six months	15 11	16 6	15 14	16 6½	17 3	17 9
All cases irrespective of feeding	17 2	17 4	17 11	17 12	18 0	18 4½

TABLE III.—*Showing Percentages of Breast-fed Infants up to Standard Weight (Newman) in Groups Arranged as in Table II.*

—	Income up to— 1*s.*	2*s.*	3*s.*	4*s.*	5*s.*	Over 5*s.*
At six months	53·5	46·5	58·2	54·2	60·6	61·7
At one year	29·4	21·4	34·8	20·7	42·1	46·1

TABLE IV.—*Showing Average Weights of Breast-fed Infants, Grouped According to Financial Position of Parents.*

			lb. oz.	lb. oz.	lb. oz.	lb. oz.	lb. oz.
Group A— In poverty ...	5·7	2*s.* 1*d.*	8 2	11 0	13 15	16 7	18 0
Group B— Not in poverty	3·68	4*s.* 11½*d.*	8 0	11 11	15 6	17 9	19 1½

Breast-feeding and Infant Mortality.

But when, in an endeavour to find whether the mortality was affected in a like degree, I inquired into the history of the older children of the mothers attending my consultation, I came up against the apparent paradox that whereas the physique of the child in poverty was less, the mortality under 12 months was also less. This, *prima facie*, would lend support to Dr. Brend's contention that poverty is not an important factor in the problem, but, to my thinking, the explanation is something quite different. The real explanation is that breast-feeding is much more common throughout the first 12 months amongst the poorer mothers, as shown in Table V.[8]

TABLE V.—*Showing Method of Feeding Infants in Various Groups Based on Financial Position.*

—		At 3 weeks.	13 weeks.	26 weeks.	39 weeks.
		Per cent.	Per cent.	Per cent.	Per cent.
In poverty, lower grade	Breast-fed	89·74	80·2	74·4	67 0
	Breast and bottle	7 18	15·0	14 7	19·15
	Bottle	3·08	4 8	10·9	13·83
In poverty, higher grade	Breast-fed	98·2	79·8	63·8	52·77
	Breast and bottle	—	9·6	9·6	13·9
	Bottle	1·8	10·5	26·6	33·3
Not in poverty	Breast-fed	89·1	70·7	64·5	58·0
	Breast and bottle	5·4	12·0	9·7	15·0
	Bottle	5·4	17·2	25·8	27·0

The additional security from fatal disease given by breast-feeding is more than sufficient to counterbalance the lessened resistance which inevitably must accompany impaired physique. This is the true explanation of the well-known improvement in the infant death-rates during the Lancashire cotton famine and the siege of Paris; death-rates which are often erroneously put forward as proofs of the small effect which poverty has on the chances of infant survival. Unemployment and increased privations in these two cases simply meant the return of the mother to the home, a greater percentage of breast-feeding, and opportunities for more domestic care and cleanliness on the part of the otherwise unoccupied housewife; in other words, a higher standard of housewifery and mothercraft with its corresponding effect on the life of the child.

It is evident to me that Dr. Brend's attempt to eliminate poverty from the causes of excessive infant mortality by a comparison between town and rural conditions must fail, since he has signally failed to prove that there is a condition of poverty in rural areas at all comparable to that in the slum areas of the towns, which areas are mainly responsible for the high infant death-rate of those towns.

Influence of Sanitary Conditions.

And I believe that his contention that housing and sanitary conditions are as bad in the rural districts as in the towns and may therefore be eliminated is just as unsound. However badly constructed or defective a country cottage may be, however disgusting its immediate sanitary surroundings, the salient fact is that these cottages are generally widely separate or at least semi-detached, and that it is always possible during part of the 24 hours for the infants to be right away from their noxious influence. On the other hand, in the overcrowded areas of large towns and in many mining villages it is a sheer impossibility for the infant to get away from the defects of his own immediate environment or that of his neighbours.

For this reason bad housing and sanitary conditions in the town spell disaster to a far greater extent than possibly worse sanitary conditions in the rural districts. Housing conditions cannot be said to be so equalised in town and country as to be fairly eliminated, and Dr. Brend's argument under this heading is, therefore, quite untenable.

Industrial Employment of Women.

Next in order Brend considers the effects of the industrial employment of women, and here, again, his argument is singularly weak. He quotes Dr. A. Greenwood, late medical officer of health of Blackburn, as follows:—

"As a result of this investigation (into the effects of industrial employment of married women) I came to the conclusion that no case has been made out for the further restrictive legislation in the prohibition of employment of women in the cotton mills of Blackburn."

But Dr. Greenwood went on to say:—

"*Of course I do not allege that industrial employment of women is harmless. It is certain that such employment interferes with breast-feeding and with the care of infants generally.* At the same time, an expectant mother needs nourishing food, and great care should be exercised before any steps are taken to diminish this food-supply. Again, a mother who is feeding her infant naturally also requires nourishing food. *At the same time, it is very regrettable that any means of bringing sufficient food into a family should be associated with detriment to the infant.*" [11] (The italics are mine in this and following quotations.)

Dr. Brend then goes on to quote Dr. Jessie Duncan, late medical officer to infant-welfare centres in Birmingham, as follows:—

"There was scarcely any difference in the weights of children whose mothers were industrially employed and those whose mothers were not."

No one would be more surprised than Dr. Duncan to find that her valuable reports on infant welfare were being used to support a contention that the industrial employment of married women is a factor of small importance in the problem of child welfare. I was in close touch with her at the time of these investigations, and what she really did say was:—

"It will be seen that in the homes where acute poverty exists there is a marked falling off in the average weight of the baby whether the mother is industrially employed or not. ..... It seems pretty certain that industrial employment has a bad effect on the infant mortality, principally because it interferes with breast-feeding. For this reason employment in a factory is more harmful than employment at home.

But *the influence of industrial employment is quite small when compared with the influence of acute poverty.* It would seem therefore that in so far as the mothers' employment reduces the acuteness of the poverty, it may even tend to improve the infant mortality. At any rate, it is doubtful whether any further interference with the employment of married women would be at all beneficial *as long as the acute poverty remains.*"[12]

I venture to believe that if Dr. Brend had read the whole of Dr. Greenwood's and Dr. Duncan's reports he would hardly have ventured to quote from them in an attempt to eliminate both poverty and industrial employment from amongst the main causes of excessive infant mortality. And the same criticism applies to his quotation from Sir Arthur Newsholme's report:—

"The most that can be inferred from the figures is that industrial employment of married women and widowed women cannot be regarded as, in itself, the chief cause of excessive infantile mortality."

In close juxtaposition to the above words Sir Arthur Newsholme writes:—

"It would be folly to infer that the industrial occupation of mothers is not a most injurious element in our social life. It may be, however, that *under present conditions ... .. the gain in diminution of poverty overbalances the serious injury due to the absence of the mother at work during pregnancy and after the birth of her infant.*

When the statistics of large communities are considered, *the evil effect of the industrial occupation of women is concealed by the preponderant action of other maleficent influences.* These may be classified, not without overlapping, under one or other of the following heads: 1. Crowding of persons on area. 2. Defects of domestic and municipal sanitation. 3. Domestic overcrowding and allied evils of housing. 4. Ignorance and fecklessness of mothers resulting in lack of mothering."[13]

The full quotations from these writers place the rôle of married women's occupation in a very different perspective to that in which it was left by Dr. Brend's emasculated excerpts. And there, I think, we may leave it.

Question of Ignorance.

The last point I can take up in this article is the question of ignorance. It may be true, as Dr. Brend says, that ignorance is as rife amongst the rural mothers as amongst those dwelling in towns, amongst the Connaught peasantry as amongst the artisans' wives of Bradford; on this question I have no exact information and venture no opinion, but if we substitute for the word "ignorance" in its limited application the much wider term of "mothercraft," covering as it does many things besides mere ignorance, then I have no hesitation in saying that the infants of the agricultural classes are much better off than those in the towns. For "mothercraft" means carefulness, personal cleanliness, clean bedding, clean floors, proper storage and preparation of food—including milk—frugality, thrift, sobriety, early hours, and, above all, breast-feeding; and all these the country woman possesses to far greater extent than her sister in the slums.

I have already remarked on the better condition of the infants of the railway workers at my old consultation in Birmingham compared with the children of the casual and other unskilled labourers living in the same district, in the same type of house, with the same sanitary arrangements, and in an equally "polluted atmosphere." One reason was the more regular wage of the father, but another reason was, I am convinced, the fact that practically all these railway workers were freshly recruited from the agricultural districts of Gloucestershire, Cheshire, Shropshire, Herefordshire, &c.

Relative Frequency of Breast-feeding.

As to breast-feeding, Dr. Brend says:—

"There is no reason to suppose that it is not as widely adopted in towns as in the country."

This statement is open to very considerable doubt; my own impression is that rural mothers are more addicted to breast-feeding, and certainly to longer continued breast-feeding, than town mothers; but again I have no definite data and refrain from dogmatism. But it is quite certain that breast-feeding is much more common and long-sustained amongst the Irish peasantry than amongst the dwellers in our English towns. In Liverpool, which contains a large population of low-class Irish, it was found—

"That amongst the low-class English the loss of infant life is very much in excess of what it is amongst the same class of the Irish population, and the reason for this is that *the Irish mothers suckle their infants much more commonly than English mothers of the same class.* To this we ascribe the lower infant mortality from zymotic diarrhœa among the Irish population in Liverpool.[14]

Is there any reason to suppose that what is the rule amongst the Irish settlers in Liverpool is not the practice, and possibly to a greater extent, away in their original homes in the heart of Connaught and Munster?

Character of Mother and Home.

That the character of the mother and, through her, the home, has a most powerful influence on the life and physique of the infant I am sure. For some years I carefully analysed the case-papers of the children attending my Birmingham consultation with a view of testing this question. And, for the purposes of this paper, I have recently done the same with case-papers from the Baby Welcomes to which I am now attached in N.E. Derbyshire.

The Birmingham infants—1051 in number—were classified according to the nature of their homes as to cleanliness, tidiness, and sanitary condition; as to the apparent care given to their clothing and person; the personal hygiene of the mothers and other children of the family; and the intelligence and willingness to learn of the mothers—in other words, as to the grade of "mothercraft" attained. The growth of the infants under such varying conditions was carefully noted, and inquiries were also made as to the life-history of other children of the same families. Table VI. shows some of the Birmingham results:—

TABLE VI.

—	Bad homes.	Fair homes.	Good homes.
Number of mothers	76 (7%)	334 (32%)	641 (61%)
Average number in families	5·5	5	4·8
Infant mortality amongst previous children	222	183	130
Fed on breast to 9 months, previous children	79%	71%	74%
Weekly income (less rent) for each member of family	2*s.* 5½*d.*	3*s.* 5½*d.*	3*s.* 8½*d.*
Weekly rent	4*s.* 1½*d.*	4*s.* 2½*d.*	4*s.* 7½*d.*

Weights of Children Attending Consultation.

—	At 3 weeks.	26 weeks.	39 weeks.	52 weeks.
	lb. oz.	lb. oz.	lb. oz.	lb. oz.
All cases { Good homes	11 1½	14 2½	16 4½	18 10
All cases { Bad homes	10 4	13 8	15 3	17 10
Breast-fed infants only { Good homes	11 9	15 0	17 4	19 2
Breast-fed infants only { Bad homes	10 11	13 13	15 15	18 0

It will be noticed that, in regard to the children previous to the consultation infants, the infant mortality becomes strikingly greater as the homes deteriorate, and that the slightly increased percentage of breast-feeding in the bad homes could not counteract the evil influences of such homes. The class of house, as shown by the rental, was much the same, and it is within my knowledge that sanitary, housing, and *atmospheric* conditions were exactly alike. Of this same area Dr. John Robertson, medical officer of health of Birmingham, writes:—

"Many of the houses, if occupied by clean active persons, would have an entirely different appearance and would be much more healthful than they are at the present time."[15]

As to the consultation infants, the growth, whatever the nature of the feeding, is much better in the good homes. A striking confirmation of these results is afforded by my Derbyshire investigations into the growth of 250 infants attending Baby Welcomes in six mining villages, as shown by Table VII.

It may be argued that the difference in weights in Birmingham is due to the difference in income in the good and bad homes, but this cannot apply to the Derbyshire figures, for in these homes poverty at present is almost unknown.

TABLE VII.—*Growth of Derbyshire Babies, irrespective of Nature of Feeding.*

—	Average number in family.	At 13 weeks.	26 weeks.	39 weeks.	52 weeks.
		lb. oz.	lb. oz.	lb. oz.	lb. oz.
Good homes	5·8	11 10½	15 4½	17 13	20 4
Bad homes...	7·4	11 10½	14 10	16 7	18 0

The infant mortality in the good homes was *95* and in the bad homes *224*.

That the home and the mother have a most powerful influence on the child is certain, and such factors cannot possibly be excluded from any consideration of the causes of excessive infant deaths in the large urban communities. It is the existence of fecklessness, thriftlessness, carelessness, and general instability amongst the mothers, and rank bad management in the homes, just as much as ignorance in its restricted sense, that is the very *raison d'être* of the educational campaign, and I maintain that the reports of Brend and Findlay have entirely failed to prove that such conditions can be ignored, or even that they are of comparatively minor importance.

Value of Infant Consultations.

Finally, I give in Table VIII. a résumé of cases dealt with at infant consultations in Birmingham and Derbyshire, the figures being taken from 250 case-papers from each district selected at random :—

TABLE VIII.

(A) Birmingham (250 infants).

	(A)	(B)
Faulty feeding ...	34	70
Indigestion	35	61
Rickets	8	9
Atrophy	1	2
Puny at birth	16	12
Scurvy	1	1

* All prior to war.

(B) Derbyshire (250 infants).

	(A)	(B)
Triplets	1 case.	—
Put back on breast	5	9
Referred for medical treatment	11	11
Extra food given to mothers	*15	†3

† War-time cases.

The puny babies included cases weighing 3 lb. at birth, 3 lb. at 14 days, 4 lb. 12 oz. at birth (induced labour), 4½ lb. at 9 weeks (21 lb. at 12 months artificially fed), 5 lb. 2 oz. at 10 weeks, and others almost as poorly developed. At the time of writing most of them are alive and doing well.

This is, of course, only one example of what is now going on all over the kingdom. Can it be fairly claimed that such work is futile or even of comparatively small importance?

It will be noticed that there is evidence in the above figures of more poverty and malnutrition amongst the Birmingham cases and much more improper feeding and consequent digestive troubles amongst the Derbyshire children, mostly coming from a coal-mining population. This is just one proof, though perhaps a small one, of the real principle which must guide us in considering the problem of infant mortality, the folly of generalisation. Every district has its own problem to solve; in one it may be housing; in another, sanitation; in another, poverty and underfeeding; in another, overfeeding or improper feeding, carelessness, and low morale; and in yet another it may be atmospheric pollution; and in most a combination of some or all of these.

Infant mortality is a hydra-headed evil. Every district is a law unto itself. Not by wide, sweeping generalisation, but by careful *local* consideration of strictly *local* conditions, will, in time, this problem be solved.

EPIDEMIC ENCEPHALITIS.

BY S. A. KINNIER WILSON, M.D., B.SC. EDIN., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN, WESTMINSTER AND NATIONAL HOSPITALS; NEUROLOGIST, FULHAM AND NAPSBURY MILITARY HOSPITALS, ETC.

DURING the last two or three months a number of cases classifiable after their main features in the general group of acute encephalitis or polioencephalitis have occurred in different parts of the country, both in urban and rural districts. These cases, as might be expected, do not conform to a rigid type; as polioencephalitis is essentially the product of the activity of a toxic or toxi-infective agent, both general and localising symptoms may be met with, and the relative prominence of either of these may be extremely variable. At one time the occurrence of ophthalmoplegia in a considerable number of instances led to the suggestion of its identity with the ophthalmoplegia of botulism, a rare disease in this country; with the result that the public, preoccupied with food questions in these days, became somewhat alarmed, especially since the lay press has persistently, if unintentionally, dragged the red herring of botulism across the trail of epidemic polioencephalitis. The subject being very much *à l'ordre du jour* at present, it is desirable to accumulate clinical and pathological evidence of precise significance before acceptable generalisations are put forth.

This, naturally, raises the question of what cases to include in the category of encephalitis. When a comparatively rare nervous disease occurs in epidemic form and professional attention is directed to it there is a tendency for various ill-recognised and perhaps obscure conditions to be ticketed with the name as a convenient means of saving patient investigation. Apart from this, the neurologist himself may well experience difficulty in assigning to their proper place incomplete, abortive, or atypical cases; in fact, until adequate data are forthcoming it is best to adopt a non-committal attitude and to avoid restriction or limitation on the clinical side. Although, therefore, careful perusal of all the recently recorded cases in this country leaves some doubt in the mind as to the propriety of some of them being styled encephalitis, we are really not yet in a position to dogmatise.

But if we seek a common denominator for the groups of clinical syndromes as given in the communications of Harris, Hall, Batten and Still, Crookshank, Melland, Christopherson and Mawer, and others, and from the various briefer reports that have appeared in the correspondence columns of THE LANCET, we are justified in asserting that a nervous disease is just now prevalent in England in epidemic form, presenting features sufficiently indicative of encephalitis, and characterised in a large number of instances by pathological drowsiness amounting not infrequently to stupor, as has not hitherto, in the experience of neurologists, been remarked to anything like the same extent in poliomyelitis, endemic or epidemic, as it occurs in England. That a resemblance should be noted between this disease and certain aberrant forms of epidemic polio-encephalomyelitis is natural, but the weight of evidence at present suggests that it is not identical with that affection. To this point attention is directed below.

Out of thirteen cases that have been personally observed, seven have been chosen as exemplifying various types of the disease, differing either in severity or in localising symptomatology.

CASE 1.—*Acute and Fatal Case with Mainly Mesencephalic Localisation.*

A. B., aged 18, residing in Hornsey, previously healthy, was taken ill on Good Friday evening, March 29th, 1918. Walking home from a sacred concert that evening, she suddenly felt an acute pain in her head and cried out to her friend "take my bag"; at the same moment it slipped from her left hand, while her left leg simultaneously gave way and she fell to the ground. She was assisted into her home and put on a sofa, moaning continuously "Oh, my head, my head!" and vomiting slightly. Dr. H. B. Brackenbury, of Stroud Green, saw her within half an hour of the onset and found her lying on the couch with her eyes closed; on their being passively opened the pupils were seen to be contracted and the axes of the eyes widely divergent; in addition the left limbs were paralysed. There was no rise of temperature and no trace of any symptoms of meningitis. During the night the condition was unchanged; occasional vomiting occurred.

The patient was seen in consultation with Dr. Brackenbury on the afternoon of March 30th. She was in bed, with eyes closed, drowsy, and apparently indifferent to her surroundings, her right hand wandering over her forehead, while she kept muttering "my head, my head."

In spite of her seeming sleepiness and apathy, it was remarkable how quickly and pertinently she answered questions and how rational were her responses by word and act in every particular. She was unable voluntarily to open her eyes, the frontalis overacting in the effort; complete bilateral oculomotor paralysis was present except for the pupillary fibres, the pupils being contracted, not dilated, and reacting to light through a minute range. The optic discs were both normal. The left side of the face was moderately weak for volitional movements; dysarthria and dysphagia were not observed and the palate moved on phonation; the tongue was protruded slightly, but definitely, to the left.

The left arm was toneless and immobile; the left leg was rather less paralysed, but equally limp. A considerable degree of impaired sensibility to pin prick was determined over the whole of the left side and limbs, including the face. On that side, further, absence of the abdominal reflex, heightened deep reflexes, ankle clonus, and an extensor response were noted; on the right no change was found.

No rise of temperature was remarked and no signs of meningitis were found on careful testing.

On April 4th the patient was admitted to Westminster Hospital under my care. It was then noticed that the pupils were dilated and the bilateral oculomotor paralysis complete. The other nervous symptoms and signs were unaltered.

During the next day the temperature rose for the first time to 101·5°, and it continued elevated till her death four days later. On several occasions in the course of that week the cerebro-spinal fluid was examined by Dr. Braxton Hicks. Coming out under moderate pressure it had a yellowish colouration, and on examination showed a considerable leucocytosis (95 per cent. being polymorphs) Smears and all sorts of cultures, including those in anaerobic media, remained uniformly negative; no recognisable organism was at any time found. The Wassermann test in the blood was negative. A blood count gave a leucocytosis of 33,600 per c.mm., 92 per cent. being neutrophil polymorphs.

[In this case the oozing of blood into the cerebro-spinal fluid unquestionably is responsible for much of the state of that fluid, as Netter also has observed.]

During these days, further, the patient's mental state presented some features of considerable neurological interest. Her closed eyes and expressionless facies belied altogether the relative activity of her mind. A well-marked degree of Witzelsucht was observed, everything being turned into a joke or made the occasion of witticisms. Any chance word overheard by the patient—as when I remarked to my house physician that the optic discs showed some hyperæmia—was taken up and made an occasion for jocularity: "Go on; I've not got any hyperæmia."

On April 6th she became incontinent and sank gradually into a deeper lethargy. At the same time some signs of meningeal irritation made their appearance. Difficulty in swallowing supervened, and with a temperature running up to 105·8° the patient died on the twelfth day of her illness.

Necropsy.—At the necropsy the brain was seen to be greatly congested, and a trifling degree of patchy meningitis was present in the interpeduncular space and elsewhere over the vertex. After hardening, a section through the mesencephalon showed the appearance in Figs. 1 and 2. The striking feature was the diffuse hæmorrhages over the section, mainly punctate, but on the right massed into a confluent group seen in Fig. 1. These small hæmorrhages were both in grey and white matter, and were found irregularly scattered from the regio subthalamica on both sides to a mid-pontine level approximately. There was also a subpial patchy oozing at a number of spots on the cortex and in the brain stem.

On microscopical examination the hæmorrhages were discovered to be almost entirely of venous origin, and intense capillary congestion reigned everywhere throughout the brain. Vessel coats were unchanged, but peri-adventitial lymphatic sheaths were here and there moderately filled with cellular infiltration, composed of polymorphonuclear leucocytes, lymphocytes, plasma cells, and polyblasts in varying degree. This cellular infiltration was not conspicuously of small-cell type and was highly irregular in distribution. Further, in various areas of white matter small collections of half a dozen or a dozen cells, mainly lymphocytes, were to be found bearing no apparent relation to capillaries. A similar very irregular patchy infiltration of the leptomeninges was recognised in which plasma cells were present in considerable numbers. At certain places in the vicinity of the older hæmorrhagic areas numbers of typical compound granular corpuscles were seen.

Toxic changes in the cells of the oculomotor nuclei and diffused in various groups in the regio subthalamica were characterised by moderate chromatolysis, nuclear eccentricity, and occasionally by the proximity of a few parasite glial cells round degenerating nerve cells. No obvious change was found in the cells of the cortex in the parts examined (frontal, Rolandic). Actual neuronophagia was not definitely remarked.

The spinal cord was not obtained.

FIG. 1.—Section through mesencephalon of Case 1. Confluent hæmorrhages on the right, and punctate hæmorrhages scattered elsewhere in grey and white matter.

FIG. 2.—Section through lower mesencephalon of Case 1. Hæmorrhagic oozing on the right, spreading into substantia nigra; also round iter.

CASE 2.—*Mild Recovering Type.*

C. D., aged 41, residing in Wandsworth, became ill on Sunday, April 7th, 1918, with simultaneous onset of dimness of vision, diplopia, and abnormal drowsiness.

Up to that day he had been in good general health and had slept well the night before.

He tested his vision himself and found he could not focus for reading with either eye; he also established the fact that his diplopia was at first crossed, the left eye image being to the right and slightly above the other. He felt a little feverish and had occipital headache, but no sickness. He remembers he was badly constipated at the outset.

In the course of 24 hours or less both eyelids began to droop, and in another 24 hours the right eye was completely closed and the left incompletely. Neither dysarthria nor dysphagia was complained of, and the limbs were unaffected.

Apart from the ophthalmoplegia the most striking feature of the case was the patient's pathological drowsiness. For the first fortnight of his illness he slept more or less all day long, being awakened for his meals by his wife. Nothing else disturbed the prolonged dream that his life seemed to have become. He was grossly disoriented in time and unable to distinguish one meal from another, yet when awakened he made no mistake in replies to questions, was always rational in conduct except for occasional incontinence, and had neither hallucinations nor delusions.

FIG. 3.—Facies of Case 2. Double ptosis, external strabismus, mask-like face, obliteration of facial lines.

On his first visit to hospital, three weeks after the onset, he was still abnormally drowsy, and slept in the out-patient hall while waiting. On examination the optic discs were normal; there was bilateral ptosis, ophthalmoplegia externa and interna, the pupils being rather large slightly unequal, and very sluggish in reaction to light, while divergent strabismus was noted and also weakness of both upward and downward movement. The facies was peculiarly expressionless, with obliteration of the facial lines. (Fig. 3.) No other cranial nerve defect was discovered, the limbs were unaffected, and both cutaneous and deep reflexes were unchanged. The Wassermann test proved negative in the blood, while lumbar puncture revealed no particular departure from normality, chemically or microscopically.

The patient has been making an uninterrupted improvement since, the ophthalmoplegia externa having entirely disappeared, though pupillary reactions are still sluggish. All the sleepiness has gone.

CASE 3.—*Ponto-medullary (Superior and Inferior) Type.*

E. F., a girl of 20, residing in Clapham, was noticed by her mother on the morning of April 18th, 1918, to be abnormally listless and quiet. As she sat in a chair her eyelids kept drooping exactly as though she were falling asleep. When the girl opened them she complained she could not see properly with either eye to do her work. She was not sick and had no obvious fever, and she answered all questions rationally.

During the course of the week the drowsiness became extreme; the patient sat about in the garden and at once fell asleep; when remonstrated with she did not appear to be aware of this unusual feature, her only complaint being that her head felt "funny" and that her eyes were "misty." At the same time it was remarked that her voice had become peculiarly high-pitched and monotonous, a modification in its character which was very striking.

In the course of a second week her condition altered for the worse; she took to her bed, was incontinent of urine and fæces, became very confused and disoriented in time and space; when she got up in the afternoon, she made mistakes in her dressing; she lost herself going about the house, and altogether became incapable of looking after herself.

On admission to hospital her condition was briefly as follows: Bilateral ptosis; weakness of lateral deviation of eyes to left, and very imperfect upward and downward movement; pupils dilated, left larger than right; reaction to light fair; well-marked ectopia pupillæ on both sides; optic discs normal. Slight weakness of left motor fifth and definite

weakness of left side of face, upper and lower; palate paralysed on the left and poor movement on the right; curious high-pitched, monotonous voice with nasal intonation; tongue protruded straight. The deep reflexes were active and the cutaneous reflexes unaltered. Stimulation of the sole of the foot always produced an unexpectedly brisk reaction of defence.

The patient's mental condition was one of apparently deep torpor, yet in response to questions she spoke correctly, if briefly, and her actions similarly were accurate. She lay all day with eyes closed or half-closed and her general immobility suggested a condition of hibernation. A variable degree of flexibilitas cerea was noted on several occasions.

Examination of the blood and of the cerebro-spinal fluid proved negative in all respects.

Since the end of May her condition has shown definite signs of improvement.

CASE 4.—*Severe Type with Prominent Mental Symptoms.*[1]

G. H., a girl of 12 years, whose home is in Edmonton, was seized on the morning of April 25th, 1918, with violent vomiting, which recurred at intervals during the day and for the next two days. On the 28th she became mildly delirious, got up and dressed herself in her mother's clothes, and muttered mostly about her school, in which apparently she imagined she was. Sometimes she acted as though she were shopping and going errands. In the course of the next day or two she became very noisy, talking and shouting loudly, and it was almost impossible to keep her in bed. On the seventh day of the illness, for the first time, she was noted to be distinctly drowsy, while her eyelids kept falling over her eyes, and by the ninth day she was excessively drowsy and stuporose and also incontinent. She lay in bed with eyes closed; when spoken to she would answer as if just wakened out of sleep; she would sit up and take her food and immediately thereafter return to her stuporose condition.

Her clinical state on admission to hospital was as follows: Bilateral ptosis, paresis of ocular movements in all directions; normal pupillary reactions, optic discs normal. Mask-like, or "Parkinsonian," facies; limbs normal; sensibility normal, reflexes normal.

A pronounced degree of flexibilitas cerea was present in all limbs. During the examination the patient seemingly paid no attention and various manipulations of the limbs did not suffice to make her open her eyes. Only when placed on her feet did she waken, but she remained oblivious of her surroundings, standing like a statue. Loud noises made in her vicinity were ignored. When ordered to sit down on a chair she looked at the observer, turned her body slightly to the right, but did not move her legs. Ordered again, she walked a step or two like a pure automaton and sat down like a piece of soft wax. When her eyes were open she frequently yawned. Her answers to questions were quite correct, though delayed. On one occasion, eating her tea, she was in the act of putting a piece of bread in her mouth when her eyes closed and the hand was kept in the same position, the bread touching her lips, for several minutes.

In the course of a fortnight, however, the condition began gradually to clear up, and at present her condition is rapidly becoming normal.

The cerebro-spinal fluid was negative, chemically and microscopically, and in the blood the Wassermann test was also negative.

CASE 5.—*Severe and Fatal Case with Meningeal Symptoms.*

I. J., aged 47, female, from a suburb of London, was admitted to hospital on May 23rd, 1918. She gave a history of having been ill for the past 11 days with severe headache and, latterly, equally severe attacks of vomiting.

Careful examination failed to show any definite localising signs in the nervous system. The vomiting was suggestively cerebral, but vertigo was not complained of, and the optic discs were normal. No local abdominal condition was discovered. The temperature rose to 100° on the evening of admission.

Two days later her condition altered for the worse. She became delirious and violent, frequently trying to get out of bed, shouting and muttering alternately, and was with difficulty restrained. The temperature rose to 102°. Still no definite organic nervous system signs were to be found. By lumbar puncture a clear fluid was withdrawn, which gave a mixed pleocytosis of 245 per c.mm., lymphocytes being in the majority, but numbers of polymorphs were also seen. No organisms were detected in numerous smears examined, and cultures on various media remained negative.

On the sixth day of her stay in hospital it was noted that the pupils were large and their reaction to light sluggish. The facies became curiously expressionless, the patient staring in front of her and paying little or no attention to her surroundings. She appeared indifferent to questions addressed to her. The reflexes were unaltered; slight stiffness of the neck was remarked for the first time, and a doubtful Kernig sign was present, on the left only.

Thereafter she gradually became more and more apathetic, lethargic, drowsy. The fixity of expression remained, and ocular movements were found to be imperfectly sustained in all directions, without any actual paralysis being detected. Cheyne Stokes respiration supervened, and the patient gradually sank, dying on the twentieth day of her illness, June 1st.

At the necropsy the brain was found to be congested generally, and a minimal degree of meningitis was present in the interpeduncular space, but nowhere else on naked-eye investigation. Macroscopical sections through the brain showed an irregular scattering of numerous minute punctate hæmorrhagic spots in grey and white matter, in cerebrum, cerebellum, pons, and medulla, and not more obvious in the mesencephalon than elsewhere. Over several small areas, several millimetres across, situated irregularly in the frontal lobes, subpial hæmorrhagic oozing was conspicuous. Nothing else of a pathological nature was found. Microscopical examination is not yet completed. There was no trace of any tubercles on the meninges or cortex or elsewhere in the central nervous system. (The spinal cord was not obtained.)

CASE 6.—*Cortical Type: Lethargy, Catatonia, Mental Symptoms.*

K. L., female, aged 31, whose home is in Pimlico, previously in normal health, complained on Whit-Monday, May 20th, 1918, of being out of sorts and of headache and fatigue. She went to business the following day, but had to return home. In 48 hours the patient became delirious, imagined a big air-raid was on, thought her room was filled with people taking shelter, spoke to them, heard guns going off and bombs exploding; in short, exhibited a whole series of visual and auditory hallucinations. On May 25th the patient occasionally became drowsy, and a slight rise of temperature occurred. At this stage she became peculiarly indifferent to her surroundings and retired into a little cosmos of her dreams, not speaking to her friends around her, frequently trying to get out of bed, and muttering about air-raids. Her sphincter control was not impaired, and she took her food fairly well.

A day or two later her mental condition rather changed, in the sense that she became more conscious of her entourage, while the hallucinations persisted, and she responded to suggestions quite after the style of the confabulation of Korsakow's psychosis. Thus she lay in bed and began to describe lovely pictures she saw around her, of old china, tapestry, old lace, oil paintings, at once picking up any suggestion from her sisters and enlarging and improving on it. She remarked that she "was having a picture show all to herself." On another occasion she felt she was going to die, and said she was ready to go to heaven. Suddenly stripping herself naked, she got up in bed and said she was going to be married to "a Prince of the Church" and had to meet him in the air. Throughout this stage her speech was quite rational for the ideas expressed; her answers to questions were apposite and in no way confused; there was no evidence of Ideenflucht, of verbigeration, perseveration, or of answering at random (Ganser syndrome).

From this point, however, the patient definitely became more and more drowsy and lethargic, and lay more or less motionless in bed, with vacant expression, or more commonly with eyes closed. It was observed that she often maintained a curious fixity of attitude for indefinite periods.

On admission to hospital the patient's clinical condition was one, to all appearance, of profound stupor. Left to herself, she lay in bed with eyes closed, oblivious of her surroundings and indifferent to the life of the ward. When aroused for her meals she took her food well enough, and in response to questions answered correctly, if slowly. No confusion of thought was discoverable at such a time, but at other times she showed restlessness and automatism, getting out of bed and wandering in a confused fashion. An advanced degree of catatonia was present in the arms and legs. When she was being photographed she obeyed requests with accuracy, yet each moment she would sink back into complete indifference, her head slowly rolling into the position assumed by gravity, while her eyes closed again, and with a sigh she would fall apparently fast asleep. (Figs. 4 and 5.) Her control over her sphincters was not maintained.

Examination of the cranial nerves showed nothing beyond inability to sustain any movement voluntarily, e.g., ocular movements, but no paralysis in the strict sense was noted. The pupils reacted to light and the optic discs were normal. The reflexes, cutaneous and deep, were similarly normal. The cerebro-spinal fluid showed nothing of

FIG. 4.—Facies of Case 6. Double "ptosis," as in sleep; expressionless face; mouth half open, as from loss of tone in the orbicularis oris.

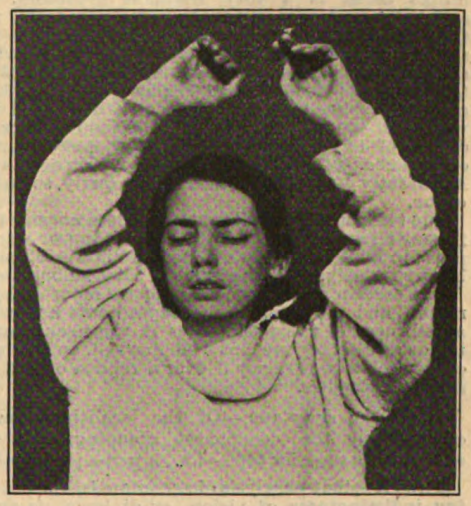

FIG. 5.—Catatonia in Case 6.

[1] This case was under the care of my senior colleague, Dr. James Taylor, at Queen-square, who very kindly allowed me to see and examine it and to cite it here, partly from notes taken by Dr. L. R. Yealland.

pathological importance, chemically or microscopically; the Wassermann test was negative and cultures were without result.

In the course of a fortnight the patient has been making distinct if slow improvement.

CASE 7.—*Regio Subthalamica Localisation; Paralysis Agitans Type.*

M. N., male, aged 46, took ill about May 24th, 1918, with feverishness and malaise, and general drowsiness. During the first week he frequently fell asleep over his meals, and at other times during the day. His movements became slow, and tremor developed in both arms and legs, especially on the right side. Articulation became tremulous. His face developed a typical fixity of expression like the Parkinsonian mask. After some two to three weeks the tremor entirely disappeared, and the patient made a notable improvement in all his symptoms. On examination at the end of five weeks the only signs are a mask-like facies, which is not so fixed as it was, and a certain slowness of movement. There are no ocular symptoms. The deep reflexes are exaggerated, with ankle clonus on the right, and a double flexor response. It has not been possible to examine the cerebro-spinal fluid.

Without here attempting a rigid schematisation, I am of the opinion that the following conclusions may be tentatively put forward.

1. *Clinical.*

Epidemic encephalitis is an acute nervous disease characterised by both general and localising symptoms; in a minority of cases the latter are not prominent.

The sexes are affected indifferently and there is no special age-incidence, infants, children, and adults alike being affected.

Its onset is relatively acute, the condition being usually established within a few days; occasionally it opens in a fulminant fashion.

General symptoms.—Of the general symptoms, apathy, lethargy, drowsiness, pathological sleepiness, stupor, absence of initiative or spontaneity is in one or other form prominent from the outset and throughout at least the earlier stages of the disease; sometimes this lethargy appears later during the illness; occasionally it is not a noticeable feature.

A degree of restlessness, of restless delirium, with a reduction of mental activity to the level of automatism, is common enough; in some of the cases I have seen the automatic reproduction of familiar movements in a purposeless fashion has been most pronounced; occasionally periods of restlessness, which it would be an exaggeration to regard as amounting to subacute mania, alternate with profound indifference or hebetude. Catatonia or flexibilitas cerea is a very frequent symptom. Delusions and hallucinations, as in any toxic psychosis, may occur. One of my cases showed a typical condition of Witzelsucht. It is a remarkable fact, however, on which nearly all observers agree, that even at the height of the illness the patient's response to requests is in act and word surprisingly accurate and rational, a feature of the disease worthy of special attention. A frequent indication of the degree of temporary impairment of mental activity is incontinence. Headache, giddiness, vomiting may be noted. Apparently epileptiform attacks, properly so called, do not occur.

The temperature is often more or less normal throughout; it may rise moderately at the beginning or during the illness; in fatal cases it has sometimes increased progressively but irregularly, after the mode of tuberculous meningitis.

In a certain percentage of cases (as reported by Economo, myself, and others) meningeal symptoms are present, such as stiffness of the neck, pains in the neck, Kernig's sign; but as a rule they are not well marked, and in any case the clinical picture is rarely if ever a replica of that of a typical acute meningitis.

Localising symptoms.—Of the localising symptoms, unquestionably the commonest grouping is of the polioencephalitis superior type—i.e., a peri-aqueductal grouping.

Thus it is that paralysis of accommodation and corresponding indistinctness of vision, or diplopia, is an extremely frequent and early symptom, and any degree of ophthalmoplegia externa and interna, with ptosis, symmetrical or asymmetrical, complete or incomplete, may be found. The pupils may be contracted, or dilated and fixed, or normal. I have observed well-marked ectopia pupillæ similar to what I have described in other mesencephalic lesions. It should be noted that the patient may have the appearance, from mere drowsiness, of bilateral ptosis where there is no paralysis. Further, inability to sustain ocular movements may be the only defect.

Involvement of lower cranial nerves to a variable extent is the next common type of nuclear invasion. The facies is often expressionless, with obliteration of the facial lines from a bilateral paresis. Palate, tongue, larynx, pharynx, may have their musculatures implicated in greater or less degree, and this implication may be essentially transient.

The predilection for motor as opposed to sensory cranial nerve nuclei points to specificity of action of the postulated virus of the disease, and is of a significance to be subsequently alluded to.

More rarely are the limbs involved; where this occurs the indications point to cortical, subcortical, mesencephalic, or pontine invasion of the corticospinal paths and not to cord invasion; this is shown by the absence of wasting and by the conservation of the tendon reflexes, as well as by the occasional occurrence of an extensor plantar response.

Sensory symptoms are insignificant or absent, or, if present, are as it were accidental (as in Case 1 above).

The diversity of localisation of the pathological process precludes the likelihood of any constant or characteristic change in cutaneous or deep reflexes.

As for the cerebro-spinal fluid, almost all the recorded cases and my own have been carefully investigated from this standpoint.

No organism has been detected by any observer, and cultures from the fluid have remained uniformly negative. It is practically always normal chemically and microscopically; pleocytosis is rare and moderate in degree, not specially lymphocytic in type. The yellowish colouration of the fluid in my Case 1, and its pleocytosis, are exceptional, and partly attributable to the hæmorrhagic condition of the leptomeninges; although the patient became steadily worse and died on the twelfth day, the fluid improved and was more nearly normal at the fifth puncture than at the first. It was absolutely sterile.

In cases where meningeal symptoms occur there may be a definite pleocytosis; it was so in my Case 5 and in Economo's Case 11, where meningeal symptoms were prominent and where the fluid was slightly yellowish in colour, with a leucocytosis of 100. In Case 5 the fluid was not predominantly lymphocytic or polymorphonuclear, but mixed; Economo does not specify the type of cell in his case.

It is distinctly curious that the fluid shows, in average cases, so little departure from the normal, in view of the perivascular cellular infiltration usually found on microscopical examination of the nervous system, including the meninges.

The duration of the disease in typical cases is very variable: it may end fatally in a few days or it may be prolonged for weeks and months. Whether there is a complete restitutio ad integrum in the recovered cases is not quite certain; thus the patient (Case 2) whose illness began on April 7th has been back to work for some weeks, but his pupils are still sluggish in their reaction to light, and he has had one or two turns of diplopia for a few minutes at a time.

Netter also has noted that in recovered cases defect of accommodation may persist "for a long time." He states that a change for the better often sets in rather abruptly, and he has seen a cure result in a case which at one time was so severe as to be associated with the appearance of bedsores on the sacrum and elsewhere.

Economo's figures for the ratio of mortality are 6 cases out of 11; Netter's, 7 out of 15; my own, 2 cases out of 13.

2. *Pathological.*

From a consideration of the findings in the two fatal cases (here reported but briefly for reasons of space), which bear a close resemblance to the details given by Economo and by Netter, it may be stated that, speaking generally, little is manifest macroscopically on the cranial surfaces beyond meningeal congestion, and perhaps a quite minor amount of patchy localised meningitis: there may also be small limited areas of subpial hæmorrhagic effusion, hæmorrhagic foci of which the largest in one of my cases was about the size of a threepenny-piece.

On macroscopical section, both grey and white matter is the seat of minute hæmorrhagic areas scattered irregularly ("piqueté hémorragique" in Netter's phrase), and occasionally massed in a confluent fashion. These, however, may scarcely be individually visible to the naked eye, the appearance being rather one of general congestion or hyperæmia. The pathological condition is essentially diffuse and variable in distribution; from the comparatively small number of necropsy reports published little evidence is forthcoming of any specific, in the sense of invariable, incidence, though no doubt the regio subthalamica, neighbourhood of the third ventricle and iter, and mesencephalon generally, are as often affected as any other part, and motor cranial nerve nuclei are involved while sensory nuclei escape.

Microscopically, the meninges are always affected in greater or less extent, a patchy diffuse thickening of the leptomeninges, with scattered cellular exudates, or with vascular congestion and perivascular cellular infiltrates, being a feature of the condition. The cells are by no means only or even mainly lymphocytic; polymorphs and plasma cells may be found. As for the cerebral substance itself, the grey matter of cortex, basal ganglia, mesencephalon, pons, and cerebellum is the seat of obvious perivascular cellular

infiltration, especially round the veins, of the same mixed type as already described. It is of varying extent and amount, while the blood vessel walls are unchanged; in places it consists of only a few cells, less than one complete layer round; many vessels may appear normal in this respect. The hæmorrhagic foci present under the microscope no special features. Minute collections of mixed cells may be seen scattered through the grey matter apparently independent of vessels.

In addition to these interstitial changes parenchymatous alterations in the shape of nerve-cell degeneration, acute or subacute, and actual neuronophagia, just as in polio-myelitis, may be seen here and there. Parasite glial cells or nuclei are occasionally found round nerve cells in a condition of early change. In one of my cases this was noticeable in the cells of the oculomotor nuclei.

Economo has found evidence of regenerative processes in his cases.

Compound granular corpuscles were discovered in patches round the older hæmorrhagic foci in my own preparations, and they have been described by Economo in one of his.

White matter and nerve fibres generally are unaffected directly, but, of course, may show secondary alterations.

Minor changes of the above general nature may be found in the cord.

3. *Nature of the Disease.*

A. Clinical and pathological evidence points clearly in the direction of an encephalitis, amounting usually to a hæmorrhagic encephalitis, which by analogy one has every reason to presume to be toxic or toxi-infective in origin. In all the reported cases the cerebro-spinal fluid has been bacteriologically negative, while both ordinary and anaerobic cultures have proved sterile. Further, no recognisable organism has been detected in the tissues on microscopical examination. Attention, however, must be for a moment directed to one of the Viennese cases.

Economo's Case 10 was that of a girl of 14, whose illness lasted about a month, with fairly characteristic symptoms, and who died on the day of her admission to the clinic. There is no record of a blood or fluid examination. Economo states specifically that the pathological appearances were those of polioencephalitis but not of hæmorrhagic type. With due aseptic precautions an emulsion of the brain and cord was injected subdurally into a *Macacus rhesus* by von Wiesner. The animal died in 46 hours, having presented the symptoms of profound stupor for at least 24 hours previously, and with a paresis of the right hind limb. On examination its brain showed all the characteristic appearances of acute hæmorrhagic encephalitis, and from it von Wiesner recovered a Gram-positive diplo-streptococcus which he was able to cultivate and from a bouillon culture of which injection into other apes produced somnolence and muscle weakness, while peritoneal injection in guinea-pigs caused death from internal hæmorrhage. It is important to note that a filtrate from the original brain-cord emulsion of the patient (Berkefeld filter) injected into a macaque monkey produced no symptoms. Von Wiesner argues, therefore, that the cause of the disease is this actual bacterial virus, this diplo-streptococcus found in the leptomeninges and in cellular infiltrates in the cortex of the first experimental monkey.

Obviously such results are of much interest and importance; equally obviously they call for confirmation. In this connexion one or two points suggest themselves by way of criticism.

(1) It is curious there is no mention of this organism in the tissues of the patient from whom the emulsion was made.

(2) It is conceivable that the brain-cord emulsion contained some quite other specific virus and that the diplo-streptococcus was accidental. That the emulsion-filtrate proved negative does not invalidate this criticism altogether, for only one animal was tried with it, which is scarcely adequate in so important a question.

(3) Von Wiesner states that *from all the human cases* whose material he was able to avail himself of (he does not say how many) he succeeded in growing this organism. Apart from the fact that other investigators have not had a similarly successful experience, he nowhere states that the organism was found in the microscopical preparations of the cases concerned, nor does Economo mention his finding such an organism. We are apparently faced with the problem of an organism as definite as a diplo-streptococcus not recognisable microscopically in nervous tissues but, nevertheless, culturable from them. In view of the unsatisfactory nature of von Wiesner's conclusions, the question whether this diplo-streptococcus is the specific cause of the disease must be left open; the negative bacteriological findings in the tissues in my two fatal cases militate against the acceptance of the somewhat summary statement in von Wiesner's communication.

B. It has been maintained that the disease is but an aberrant or unusual type of epidemic poliomyelitis, or polio-encephalo-myelitis. Needless to say, there are obvious resemblances between the two classes of case—this particular encephalitis, and the familiar polio-encephalo-myelitis—which scarcely require pointing out. Anyone familiar with the history of the various epidemics of poliomyelitis within the last decade, say, is conversant with the occurrence of pure polioencephalitis cases resembling in some respects those occurring at present. But apart from epidemics polio-encephalitis of the common variety occurs sporadically all the year round, and cases belonging to that category are very familiar to the neurologist, who in out-patient departments is frequently meeting with instances of infantile cerebral hemiplegia, say, from recent polioencephalitis. Take, as a typical example, the following case:—

O. P., aged 2½ years, female, took suddenly ill on April 10th, 1918, with malaise and vomiting and within a few hours had a series of convulsions of epileptiform nature, with unconsciousness, cyanosis, &c. When these came to an end, about 24 hours after the onset, the child was found to be paralysed down the right side and was completely aphasic: before she had been prattling normally. On examination the characteristics of right hemiplegia were found.

A case such as this, in my opinion, would be taken by any neurologist as the common type of sporadic polioencephalitis, and a brief consideration will show in what respects the type it represents differs from the variety of disease that is the subject of this communication.

(1) The lethargic element, so strikingly manifest in the present epidemic, is largely wanting in the ordinary cases of polio-encephalo-myelitis met with hitherto in England.

(2) Lethargic encephalitis appears to occur in winter and spring; poliomyelitis in epidemic form is essentially a disease of summer and autumn.

(3) The former, further, is certainly showing a greater percentage of incidence among adults than has ever occurred in epidemic poliomyelitis.

(4) The insignificant and minor changes in the spinal fluid in the condition, speaking generally, are not consistent with what is constantly found in acute cases of ordinary polio-myelitis.

(5) Meningeal symptoms occur in a much larger proportion of cases in poliomyelitis than in the present epidemic encephalitis.

(6) In not a few of the present cases there is much less, and a more patchily distributed, perivascular cellular infiltration than in the average case of poliomyelitis.

(7) As Professor F. W. Andrewes remarks (in an introduction to the paper by Christopherson and Mawer) it is certainly curious that if the present epidemic is merely one of aberrant polio-encephalo-myelitis only aberrant cases seem to be occurring. The case just quoted, of typical polioencephalitis, does not go contrary to this statement, for such instances are not appearing in an increased degree just now, as far as my experience goes.

(8) The hæmorrhagic element is proportionately considerably more prominent, pathologically speaking, than in epidemics of polio-encephalo-myelitis of the usual type.

(9) As far as I am aware, no family cases have occurred in the present epidemic; such are far from infrequent in ordinary poliomyelitis, epidemic or otherwise.

In brief, the evidence now available suggests that in the present epidemic we are dealing with a form of infection akin, no doubt, to the virus of poliomyelitis, but not identical with it—a form of infection which has a special tendency to involve the oculomotor nuclei, and the dissemination of which through the brain is associated with the special clinical symptom of lethargy or stupor.

C. An epidemic of cases apparently in every way analogous to those under consideration occurred in the beginning of 1917 in Vienna, and a painstaking description of them will be found in the papers of Economo, already referred to above. He coined the name encephalitis lethargica for the condition, being duly impressed, as we in England have been, by the prominence of lethargy in the clinical picture. Netter has recorded the occurrence of a similar epidemic in Paris and its environs this spring, and he adopts the name of encéphalite léthargique épidémique. The objection may be advanced that it is illegitimate to apply a clinical adjective to a pathological substantive; not the encephalitis, but the patient suffering from it, is lethargic. For that reason it appears preferable to omit the qualifying epithet, unless one follows the grammatically more correct suggestion of Batten and Still, and speaks of epidemic stupor. As a pathological terminology is always preferable to a clinical, epidemic encephalitis seems to me to be the best description at

present justifiable, at least until we are more certain of the nature of the condition.

For the student of the subject should not forget that in the first place sleepiness, lethargy, or stupor may well accompany any form of encephalitis, and, in the second, it is not clear we are dealing with an entirely new affection.

He may be referred, for instance, to the excellent monograph of Chartier (1907) on acute non-suppurative encephalitis. In it will be found collected a series of cases of acute encephalitis, mainly from the service of M. Comby of the Enfants-Malades in Paris, more than one of which—for example, his Case 3—may well be regarded as belonging to the same category as this "new" disease. In this case, a child of four months, torpor and ophthalmoplegia were prominent symptoms.

Again, in the acute encephalitis of influenza, and in numerous toxi-infective conditions, it has long been recognised that symptoms may occur closely analogous to those under review.

Economo refers to the mysterious "nona," an epidemic which took place in Italy and Hungary in the spring of 1890. A full and informative review of that question was published by Longuet in 1892. Reference to it also will demonstrate to the student that there is nothing novel in the appearance of stupor, lethargy, or even catatonia, in the course of encephalitis. The contention, now probably all but forgotten, was then advanced, apropos of nona, that the cause of the pathological sleep frequently noted in that affection was the incidence of the morbid process on the grey matter of the iter and anterior part of the floor of the fourth ventricle. Sleep, physiological and pathological, was thus "localised" in these important structures. There is more support for this interesting contention than may appear at first sight, but I cannot go further into the matter in this place.

Reference may also be here made to a valuable paper by Breinl describing a "mysterious disease" which occurred in Queensland and New South Wales in 1917 and which had an alarming mortality. This paper will repay careful perusal, for it gives an idea of the extent to which the disease spread in these States and adduces evidence showing that the affection closely resembled the disease with which we are concerned. In particular the pathological appearances, the trifling changes in the spinal fluid, and some of the clinical data suggest an intimate relationship to epidemic encephalitis. Unfortunately, I have been able to procure only the first instalment of Breinl's paper, and cannot therefore quote his conclusions.

Conclusion.

In conclusion, what appears to be new is the occurrence in epidemic form of cases of encephalitis not to all appearance due to the action of a known infective or toxi-infective agent, but presenting clinical symptoms any or all of which have been noted in various kinds of encephalitis with which the neurologist has long been conversant. Unquestionably there is now afforded an excellent opportunity, thanks to modern methods of investigation, of solving the problem of the affection, and thereby incidentally of clearing up much that has been obscure in our knowledge of encephalitis in general.

BRITISH ORTHOPÆDIC ASSOCIATION.—The annual meeting of the British Orthopædic Association will be held on Friday, July 26th, and Saturday, July 27th, at the rooms of the Medical Society of London, 11, Chandos-street, W. On the morning of the first day the President of the association, Mr. E. Muirhead Little, will deliver an address; this will be followed by a discussion on the Indications, Technique, and End Results of Tendon Transplantation in Gunshot Injuries of Nerves, to be opened by Captain T. P. McMurray, R.A.M.C. On the second day Mr. D. M. Aitken will open a discussion on the Abbott Treatment of Scoliosis. The programme on both days will include short communications from other members of the association.

THE OPERATIVE TREATMENT OF TRIGEMINAL NEURALGIA.*

BY J. HUTCHINSON, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR, AND SURGEON TO THE LONDON HOSPITAL.

FOR epileptiform neuralgia involving the superior and inferior maxillary divisions of the fifth nerve the only treatment which can afford a lasting cure consists in operating on the Gasserian ganglion.

From the time of the first performance of excision of the ganglion in April, 1890, by Mr. William Rose, it was considered necessary to divide or pull away the roots above the ganglion, thus destroying the ophthalmic division and rendering the cornea permanently insensitive. In many of the cases ulceration of the cornea subsequently damaged vision; in some the eye had to be removed. Moreover, if the ophthalmic division be excised the cavernous sinus is almost certain to be opened up, and the risk and difficulty of the operation thereby increased.

These considerations, together with the fact that in only 25 per cent. of the cases is the ophthalmic division materially involved in the neuralgia, led me in 1898 to urge that it should always be spared, the greater part of the ganglion being removed, together with the second and third divisions, by a line of section shown in Fig. 1. This modified operation I have since carried out in over 60 cases, in all of which the ganglion has been approached by the temporal route.

The Modified Operation.

The chief points may be thus summarised:—

1. The patient throughout the operation is seated in a dental chair.
2. The flap, with its base at the zygoma, is of ovoid form, small in size, and kept wholly within the hairy scalp. The scar left is inconspicuous and completely hidden later by the hair, as seen in Fig. 2.
3. After carefully trephining the squamous part of the temporal bone the dura is detached and the opening enlarged, especially downwards, until it allows of the introduction of a broad flexible metal retractor. It is quite unnecessary to turn down a large bone flap (a method apt to leave considerable disfigurement).
4. The operator works inwards towards the foramen ovale, which lies opposite to the pre-glenoid tubercle, and the foramen spinosum, which lies about 3 mm. behind and a little external to the exit of the inferior maxillary nerve. The middle meningeal artery is now tied and divided between two ligatures (fine silk).
5. The dura is further raised until the ganglion with its two main branches, superior and inferior maxillary, are exposed. The latter branch is cleared as far forwards as the foramen rotundum. The ganglion is removed by three lines of section made with a fine, blunt-pointed, sickle-shaped knife. One cut divides the lower maxillary division at the foramen ovale, another the superior maxillary at the foramen rotundum, the third passes horizontally below the ophthalmic division, which is thus spared. This is, of course, the most difficult and critical part of the operation; it is essential that oozing of blood should not hinder the surgeon from seeing exactly what to cut.
6. Two small drainage-tubes are left in the wound; the flap is sutured in place without any replacement of bone.

A good head-lamp is essential during the operation, together with great care in the use of the retractor so as to spare the brain from injurious pressure, and endless patience in securing a bloodless field of vision. Unless the ganglion and its main branches are clearly exposed, it is, of course, impossible to perform the section aright.

Hæmorrhage, chiefly from minute vessels coming through the foramina, is the chief difficulty, and the operation takes from 50 minutes to 1½ hours to perform. I have not found adrenalin of any use in checking the bleeding; in a few cases preliminary ligature of the external carotid artery has perhaps been useful, but in the great majority it has been dispensed with. Its performance adds to the probable length of the operation.

Results of the Operation: Mortality.

Considering the advanced age of most of the patients (many have been from 50 to 60, and one was 72 years old) and their exhausted condition from the effects of years of agonising pain; taking also into account their malnutrition from inability to masticate their food, &c., and often their edentulous state from fruitless removal of teeth, the results of the operation have been most satisfactory.

First, as to the mortality of the operation, which by many is still held to be formidable. Until the last month, out of over 60 cases I operated upon not one proved fatal.

My solitary death was in an old man, the subject of both ataxia and true epileptiform neuralgia. He was so feeble that I tried to avoid operation by resorting to alcohol injections—which made him worse—and ultimately the Gasserian ganglion was excised. His dura mater was the thinnest I have ever seen and it gave way in detaching it from the skull. Probably owing to this there was undue pressure on the brain during the operation. He died of sudden cardiac syncope an hour after its completion.

There were a few others in which anxiety has been felt, in two cases recurrent hæmorrhage necessitated opening up the wound within 24 hours, but this is the only patient I have lost out of some 80 operations either on the Gasserian ganglion or its main branches.

Professor Krause, who did the complete operation (including the ophthalmic division) 36 times, had 8 deaths—i.e., 22 per cent.

Sir Victor Horsley had 6 deaths out of 120—i.e., 5 per cent. I understand that Professor Harvey Cushing's mortality has been very low, and although the earlier records collected from the work of a

* Part of a lecture delivered at the Royal College of Surgeons of England.

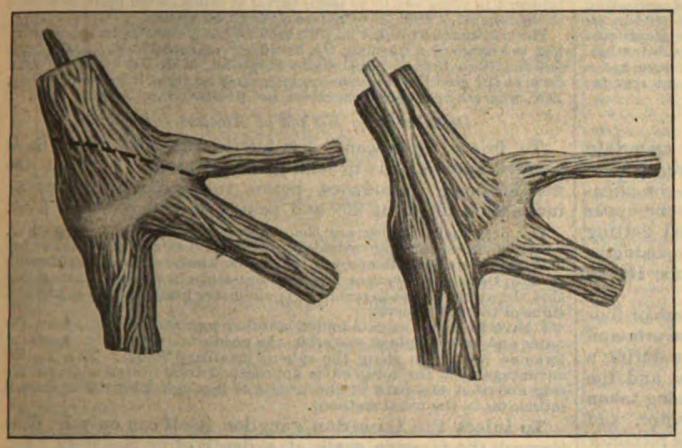

FIG. 1.—The Gasserian ganglion with its roots and three branches seen from both aspects. The dotted line indicates the section which is made to spare the ophthalmic division. The removal of the ganglion is completed by division of the superior maxillary trunk at the foramen rotundum and of the inferior maxillary at the foramen ovale.

great number of operators gave a death-rate of 20 per cent. or more, it may safely be affirmed that the risk of the modified operation I have described is very small indeed—about 1 or 2 per cent.

Permanence of Cure.

Experience with peripheral neurectomy and alcohol injections has usually obtained respite from the neuralgia for a varying period of months, but return is practically invariable.

Moreover, spontaneous cure of true epileptiform neuralgia is unknown; it goes on with increasing severity until the patient's death. Some operators have been content to divide the second and third branches just beyond the ganglion; this is not sufficient, as speedy union is certain to occur. I operated in one such case after the performance of this extra-ganglionic section by another surgeon owing to the return of sensation and of intense neuralgia *within a year*.

But after removal of the ganglion, so far as my experience yet goes, there is no reproduction of the nerves; the cases which have thrown doubt on this have proved to be incomplete removal of the superior maxillary branch at the first operation. I have followed up many cases for over ten years, some for nearly 20, and the neuralgia has not returned. This statement is true of the great majority, but I have met with a few exceptions, difficult to explain. One or two of them will be referred to later.

When I first brought forward the method of operating so as to spare the ophthalmic trunk I was assured that the neuralgia would inevitably return in this, but fortunately the lapse of years has not borne this out. In only one of my patients has this recurrence taken place, some ten years after the operation. In her I resected the supra-orbital nerve with complete success so far (three years).

Abbe in 1903 brought forward his method of dividing the superior and inferior maxillary trunk (without removing the ganglion) and urged, as I had done five years before, that the ophthalmic division should be left alone.

He plugged the foramina rotundum and ovale with rubber or other suitable material just beyond the points of section. In this way Abbe maintains that union of the two divided trunks and recurrence of the neuralgia is prevented. I am not sure that this method is so thorough as mine (Abbe admits a fair percentage of recurrence, partial or complete), nor do I think it is a less severe form of operation. The main steps of exposing the ganglion, &c., are precisely the same in the two procedures, and the time occupied in plugging the foramina cannot be less than in excising the greater part of the ganglion.

But as regards the main point, that of sparing the ophthalmic division and thus of avoiding all future danger to the patient's eye, we agree completely, and I believe the present position is that for all cases of undoubted epileptiform neuralgia either Abbe's method of operating or my own is the safest and best to follow.

Frazier and Spiller have proposed to divide the sensory root of the ganglion alone before it pierces the dura mater, and it is possible that this has been successfully carried out. But this method seems to me too hazardous and uncertain ever to come into favour, moreover it has the disadvantage of destroying the ophthalmic division.

Deformity or Other Untoward Result of the Method.

With the opening in the skull limited to the squamous portion, and the skin incision concealed by the hairy scalp, there is no subsequent deformity to be feared.

This will be seen by reference to Fig. 2, showing the two sides of the face from a patient operated on ten years previously. It is difficult to detect on which side the operation was performed; slight flattening of the temporal region from atrophy of the paralysed temporal muscle alone indicates it.

Of course the cheek, inside and out, together with the gums, palate, and tongue, on the operated side are left insensitive.

It is surprising how little inconvenience is produced, and the patient is able to masticate food far better than before the operation.

Before operation every meal was a torture. And if only medical men would abstain from removing healthy teeth in these cases of epileptiform neuralgia before they come to operation the patients would be still more comfortable after it. This pernicious and useless removal of sound teeth is rarely abstained from, no doubt from the widespread belief (advocated by the late Sir Victor Horsley and others) that epileptiform neuralgia is really a spreading neuritis of dental origin. Space does not allow me to adduce here all the arguments against this theory, for which there is no proved foundation. I will only mention two.

The fifth nerve is a mixed motor and sensory nerve; true neuritis would involve loss of sensation and muscular power. On the other hand, if epileptiform neuralgia lasts 20 years we never see it produce

FIG. 2.—The two sides of the face ten years after operation on the Gasserian ganglion by the author's method. The deformity left is so slight that the reader may be left to determine which side was operated upon.

either (apart from operative interference). Again, if a spreading neuritis travelled from one division of the fifth to another the inflammation must affect the Gasserian ganglion; in epileptiform neuralgia the ganglion is quite normal to microscopic examination. The latter fact has been proved over and over again. I have had a number of ganglia examined from my cases, always without results; there is no trace of neuritis.

Other Complications.

After the operation facial paresis or paralysis of uncertain duration has occurred in a few cases, *on the side operated on*. I have come to the conclusion that this infrequent complication is due to detachment of the dura mater from the upper surface of the petrous bone, and hence to blood getting through the small openings leading to the aqueductus Fallopii. With due care one should avoid this, if my explanation be correct.

A more important complication, met with in three or four of the 60 cases, has been weakness of the opposite arm and leg apparently from retractor-pressure on the brain during a long operation. Recovery from this is very slow and the risk of its occurrence points to the greatest care being taken throughout the operation in the use of the retractor, and frequent relaxation of all pressure by depressing the retractor against the bone or removing it for a time.

Satisfactory Results of the Operation.

Finally, it should be admitted, and will be by all who have extensive experience of operations for this dire disease, that sometimes the result is disappointing, for the following reason. The patient owing to years of suffering and disappointment (perhaps from repeated failure of alcohol injections or neurectomies) has become a confirmed neurotic. Careful selection of cases is necessary before deciding to perform one of the most difficult and protracted operations in the whole range of surgery. But when every possible drawback has been reviewed, when every argument of the opponents of operation has been heard, the conclusion remains that it has given a long series of permanent cures for one of the most inveterate and terrible diseases which afflict humanity.

Nearly a thousand years ago the Arabian physician Avicenna described it as *tortura oris*—facial agony. Until Wm. Rose's pioneer operation 30 years ago it remained absolutely incurable, and even Rose gave up his method after a time. I am certain that the modified operation, which spares the ophthalmic division, constitutes a real advance. It is attended with little danger to life and is free from subsequent risk to the eye.

I am fully aware that there is a prevalent belief that permanent cure after any form of operation is unknown, that sooner or later recurrence will show itself. Even a well-known surgeon whose name has been attached to a particular method, Professor Sébileau, declared a year or two ago that he had given up operating on this form of neuralgia as his results had been so unsatisfactory, especially as regards recurrence.

The use of the term radical cure to any operation—whether for hernia or neuralgia, &c.—may be objected to by some. But if complete relief from attacks of agonising pain—relief felt the day after operation and continuing for 10 or 20 years without the smallest recurrence—does not constitute a permanent cure I know no other words by which to describe it.

With the complete freedom from pain and the ability to properly masticate solid food the patient gains in weight and vigour to a remarkable degree. In short, while the operation is one of the most difficult in surgery, its results are amongst the most satisfactory of any the surgeon will meet with in his work.

Results of Treatment by Alcohol Injection.

The method of alcohol injection, either of branches of the fifth nerve or into the foramen ovale and its neighbourhood, is at present much in vogue. From personal experience, as well as observation of many cases in which it had been performed by others, I am sure that it is but an indifferent substitute for the operation on the Gasserian ganglion.

In some cases no relief whatever is given by the alcohol injection; in others temporary anæsthesia and freedom from pain may last from a few months to about a year, but recurrence of the neuralgic attacks is practically certain. If the injection be repeated a shorter interval is the rule; as a rule the patient is left ultimately in a worse condition than at first, and the prognosis of the major operation is distinctly prejudiced.

For example, I saw in Belfast an elderly woman who had travelled to London and submitted to alcohol injections no fewer than 15 times at the hands of one of the prominent advocates of this method. The epileptiform neuralgia was in her case finally worse than ever, and the repeated failures led her to refuse the offer of cure by operation.

Some writers have claimed success from alcohol injection prematurely; thus one physician reported 31 "cures" out of 33, but in 19 of his cases the result had been followed up for less than nine months.

The most candid report I have yet seen is that given by an Austrian physician, Dr. Flesch. Of 62 cases in which he had employed alcohol injection there were 8 "cures," but in each of these only a peripheral branch of the fifth nerve had been injected. We may conclude with certainty that none of these were cases of real epileptiform neuralgia, for in this no operation on a peripheral branch—however thorough the destruction of the nerve—ever effects a permanent cure. Of Dr. Flesch's other cases, 54 in number, *he found that the neuralgia returned in every one*, in 50 the interval of relief varied up to 18 months at the longest. Even in war-time a year soon passes.

The treatment by injection with alcohol has invariably in this country had the name of a German, Dr. Schlösser, attached to it. I may point out that two French ophthalmic surgeons, MM. Pitres and Verger, deserve the credit of its introduction; they brought it forward in July, 1902, whereas Schlösser's paper was not published until a year later.

Drawbacks to Method of Alcohol Injection.

To inject the second division of the fifth nerve it is usually approached in the pterygo-maxillary fossa, the needle being introduced below the malar bone at an inclination of about 20° and passed to a depth of 4·5 cm.

The drawbacks to this are that there are no guides to the nerve, which is, moreover, approached from its lateral aspect; that anatomical obstacles in some skulls account for frequent failure; and that untoward results, such as diplopia or loss of colour-sense in the eye, have shown that the alcohol is apt to reach the oculo-motor nerves in the sphenoidal sinus or the optic nerve.

I have in a few cases adopted another way of approach, from the outer and lower angle of the orbit, the needle being passed towards the foramen rotundum along the spheno-maxillary fissure. This has the advantage that the foramen is approached from in front and not the side and that the path of the needle is through fatty tissue and not muscle (as in the usual method).

To inject the Gasserian ganglion itself can only be done through the foramen ovale at a depth of no less than 7 cm. from the side of the cheek.

It is undoubtedly possible in many skulls to reach the foramen, though what happens to the alcohol injected and exactly where it goes appear to me to depend upon "the Fates and Destinies, the Sisters Three, and other branches of learning," rather than upon any special skill or knowledge of the physician. In some cases the alcohol probably diffuses itself in the subarachnoid space and does no harm; in some the posterior part of the ganglion may be reached by the needle.

It is an open question whether this method gives any better result than injecting the branches of the fifth nerve that are chiefly affected by the neuralgia. In either case, if the latter be of the true epileptiform type, relief is uncertain and at the best temporary.

Choice of Method.

My own feeling is this: When the patient wishes it and fears the major operation a careful trial of alcohol injection should be made, but if this fails the good prospect of a permanent cure by excision of the Gasserian ganglion (or else by Abbe's operation) should not be unduly deferred. Where the neuralgia involves both superior and inferior maxillary divisions, as it does in most of the advanced cases, nothing short of the major operation is likely to be successful. In a certain number, however, the second division is alone involved for several years, and in these it may be worth while to resect the trunk of the superior maxillary, after trephining in the manner described at the beginning of this paper between the ganglion and the foramen rotundum.

I did this operation first in 1902, but can only speak as to the results of four cases. In all relief was obtained for several years, in one there was entire freedom from recurrence for six years, but then the tic douloureux developed in the third division (inferior maxillary). In this case and in another of the four I was obliged to remove the Gasserian ganglion at a second operation, which was rendered easy by the previous performance of the first one.

Recurrence on Opposite Side.

In conclusion, attention may be drawn to a fact of much interest, which, so far as I can ascertain, has hitherto escaped comment.

Perhaps the most striking feature about epileptiform neuralgia is its one-sided distribution, but experience has now shown that after a successful cure by operation on the Gasserian ganglion there is a definite tendency—after a varying number of years have elapsed—for the disease to develop in *the opposite* fifth nerve. As before, the spasmodic attacks of pain may be confined to one division only, or they may involve both second and third.

If there were no other reason for discrediting the view urged by the late Sir Victor Horsley that epileptiform neuralgia is due to a neuritis set up by dental irritation, this fresh development (on the other side of the brain) would alone be conclusive.

I have met with three cases, and the question of their treatment is obviously a difficult one.

One does not wish to paralyse the masticating muscles on both sides, and there ore the alternative lies between resecting the superior maxillary by the intracranial method (when the neuralgia is confined to this division) and operating on the Gasserian ganglion, whilst preserving the motor root and its continuation into the inferior maxillary nerve.

Alcohol injections were tried without success in two of the three cases before resorting to open operation. When last seen the result of the second operation in all three cases was satisfactory, and fortunately this recurrence of the neuralgia on the opposite side of the head is quite uncommon.

On the present occasion it is only possible to refer to the operative treatment of epileptiform neuralgia of the fifth nerve, to emphasise the importance of preserving the ophthalmic division during the operation, to point out the small risk which now attends it, and the permanence of the cure that is to be hoped for in properly selected cases.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF EPIDEMIC LETHARGIC ENCEPHALITIS.

BY A. J. RICE-OXLEY, M.D.DUB., M.R.C.P.LOND.

IN the following case the general indication pointed to it being one of those obscure cases recently reported of epidemic lethargic encephalitis rather than cerebral hæmorrhage or cerebro-spinal meningitis. This opinion was based on these facts: character of onset, the fever, somnolence, suspicions pointing to some ophthalmoplegia, regular and slow pulse, facial and lingual weakness, severe pains in neck (referred pain), age of patient, and absence of meningeal symptoms.

The patient, aged 74, appeared in her usual not very good health when, on May 17th, 1918, she went to visit some friends, where she arrived thoroughly exhausted. While at lunch she suddenly ceased talking, became confused, and threw her arms wildly about; she vomited freely for some little time. No definite loss of consciousness or signs of paralysis. The mental confusion continued. Severe frontal and cervical pain developed, with, at first, inability to sleep on account of the pain. T. normal until the 22nd; then rose to 100° and next day to 102°; thereafter between 98° and 102°. Patient had then become very drowsy and lethargic, capable of being roused but soon relapsing intosomnolence, with irregular Cheyne Stokes breathing; pulse regular, rather slow. Tendency to incontinence of urine. Tongue dry and typhoidy-looking. Bowels confined but acting to drugs.

May 23rd: When roused speech is heavy and difficult to interpret, but the patient appears to understand what is asked, but has difficulty in answering the question. The eyes are closed, but opened when requested. Resistance with some force is offered when eyelids are opened with the finger. Eyes slightly drawn over to right; some unsteadiness in lateral movements, but no nystagmus; some facial weakness; movements of tongue halting and uneven. Upper limbs quite normal; grip of hand fair; no noticeable spasticity or rigidity or flaccidity. The same holds good as regards lower limbs. Knee-jerks could not be elicited. No signs of Kernig, Babinski, or Brodzinski. Abdominal reflexes are normal; no marked tache cérébrale. Very definite tenderness in region of neck, especially over lower cervical area; no rigidity; complete incontinence of urine.

Dr. J. A. H. Brincker, who most kindly saw the case with me, advised lumbar puncture.

This was done May 25th; about 40 c.cm. of cerebro-spinal fluid withdrawn. The fluid was clear except for a small quantity of blood which accidentally got into the fluid. The patient improved very distinctly for a short time and appeared to recover a definite degree of consciousness, but about half hour later she was taken with a seizure associated with unconsciousness. Convulsive movements of the facial muscles; eyes now diverted to left; failure of respiration and heart's action. She very slowly improved under thyroid injection and artificial respiration, &c., but never recovered consciousness and died on May 28th, noticeable features being incessant nystagmus, rapid, jerky, irregular respiration, and a much quickened pulse-rate.

Examination of the cerebro-spinal fluid gave a result in complete agreement with the findings in other cases of this disease. The patient had certainly been in somewhat failing health since March, when I attended her for an acute attack of intestinal irritation, the exact cause of which I could not determine. Had the cause being lying dormant and suddenly resumed its fatal activity?

London, W.

THE OCCURRENCE OF SKIN LESIONS DURING TUBERCULIN TREATMENT.

BY A. G. M. GRANT, M.D. EDIN., D.P.H.,
TEMPORARY MEDICAL SUPERINTENDENT, MANCHESTER SANATORIUM, ABERGELE.

FOLLOWING on the administration of tuberculin the presence of skin manifestations is uncommon. A passing erythema is very occasionally seen, but any more lasting and definite lesion is rare. Papular eruptions of the nature of tuberculides have been described by different observers, but even in the recent exhaustive works on tuberculosis only meagre reference is made to them. Owing to the rarity of the condition the following case may be worthy of record.

A woman, aged 24, came under sanatorium treatment on Dec. 16th, 1916; had suffered from a cough for a year. Seven years previously acute pains in and swelling of ankles; in bed for three weeks; otherwise health had been good. Involvement of whole of upper lobe and apex of lower lobe of right lung, with numerous tubercle bacilli in sputum. No cardiac murmurs. Progress after admission satisfactory and uninterrupted; temperature remained normal; fit for moderate exercise.

On Feb. 16th, 1917, first injection of tuberculin B.E., 0·001 c.mm.; four days later 0·0015 c.mm. In 18 hours after second injection temp. 99° F., headache, cough increased, and over affected portion of right lung crepitations more numerous. With rest in bed focal reaction gradually subsided. On March 3rd pain around knees and elbows, feeling as if she had been badly bruised; some hours later papular eruption in these sites on extensor aspects. The nodules were very slightly raised, inflamed, and somewhat tender to the touch, resembling an erythema nodosum. Within 24 hours they had disappeared, leaving hæmorrhagic spots varying roughly in diameter from 3 mm. to 15 mm.

On March 8th a similar eruption associated with pain appeared on ankles and dorsum of feet, spreading round towards the soles. The following day the rash was seen on extensor surfaces of forearms; on March 14th small petechial hæmorrhages on posterior aspect of shoulders. On March 17th there suddenly developed œdema of left parietal and frontal region, which for a few hours closed up left eye. On following day œdema of left hand; on March 28th right hand similarly affected. This quickly passed off and the eruption gradually faded, leaving a brownish stain on the skin; on March 27th, April 1st, and April 11th recurrences, but to lesser degree, of hæmorrhagic lesions, preceded by slight papular eruption over extensor surfaces of arms and legs, with pains in elbows, knees, and ankles. The appearance of the rash was associated with profound constitutional disturbance, marked by anorexia, sickness, and acute pain in epigastrium, severity of pain coinciding with a fresh eruptive crop. On March 23rd epistaxis; on 24th slight melæna.

During the whole of this period patient seemed tired and worn out, although temperature was only slightly raised. After middle of April no return of eruption; general condition improved. Examination of lungs revealed, however, a definite spread to lower half of right lower lobe. A left-sided pleurisy developed in May; signs of infiltration of lower lobe of left lung. Further progress slow; she left sanatorium in July.

Scrapings from the papules and hæmorrhagic patches were examined microscopically; T.B. not found. Arneth counts were done at intervals, but did not show deviations corresponding with altered clinical state. Index 78 before injection of tuberculin on Feb. 16th. On Feb. 23rd, March 9th, March 30th, April 14th, June 25th, and July 9th it was 81, 76, 82, 78, 78, and 73 respectively.

The exact nature of the production of these skin affections is still not definitely known.

In a few cases tubercle bacilli have been demonstrated in the lesions, and this has led to the belief that the tuberculides are caused by the dissemination of attenuated bacilli which are readily destroyed by the specific cellular defence of a hypersensitised person. The rapidity of the destruction of the bacilli explains the difficulty of their detection microscopically. The eruption is not due to the presence of any living bacilli in the tuberculin, as with a tuberculin free from ultra microscopic particles of bacilli similar skin changes have been produced. Tuberculin acts indirectly by causing a focal reaction, and thus lets free increased numbers of tubercle bacilli into the blood stream. With reference to the above case several other patients were treated with the same tuberculin and showed no untoward symptoms.

In connexion with this skin manifestation, Dr. Marcel Pinard, of the French Army, has observed acute nettlerash with œdema develop 12 to 15 days after the use of poisonous gases by the Germans, and followed later by active pulmonary tuberculosis. It is interesting to note that the lapse of time between the toxic stimulus and the skin eruption coincides closely in both instances, 15 days supervening between the first injection of tuberculin and the appearance of the papules.

I have to thank Dr. C. F. Walker, medical superintendent, Westmorland Sanatorium, for permission to publish this case.

NOTE ON HÆMATEMESIS AS A COMPLICATION OF APPENDICECTOMY.

BY E. DRYBROUGH-SMITH, M.D., CH.B. EDIN.

THIS case simulates in many respects the condition known as post-operative hæmatemesis, a serious complication, with a death-rate equivalent to 69 per cent.[1] Perhaps by recording the case other cases of a similar kind may be brought to light and views expressed as to the frequency and etiology of this uncommon complication.

A boy, aged 12, had attack of appendicitis; acute during first four days; continued in subacute form for four weeks, during which time temperature rose each afternoon to 100° F. and he complained of sharp shooting pains in right lower quadrant of abdomen. No symptoms of stomach disease; no vomiting during attack and appetite fairly good after the first four days. He suffered from constipation, which required aperients. He looked ill, pale, and thin.

After temperature had been normal for two days I decided to operate. Castor oil administered night before; enema of soap and water at 7 A.M. on day of operation—Feb. 12th last. At 11 A.M. he was given chloroform. A few minutes after its commencement he vomited repeatedly; on continuing anæsthetic he became pale and ceased breathing. Head lowered; artificial respiration; 0·5 c.cm. pituitary extract hypodermically, followed by saline. When he recommenced breathing open ether was administered; on this he did fairly well; operation proceeded with. Vomiting caused escape of a few loops of intestine; otherwise no great manipulation of bowel.

On opening abdomen exploration of gall-bladder and pyloric region with two fingers; nothing abnormal. Search at once made for appendix, which was slightly adherent to outer side of cæcum. It was easily brought out and removed. Wound closed without drainage. Appendix showed circular ulcer of mucosa within an inch of base.

Before patient left operating table and while still semi-conscious he vomited dark-brown fluid (altered blood). This vomiting continued all day at intervals; on each occasion the same fluid ("black vomit") brought up; quantity 3 or 4 ounces to 8 or 10 ounces. He complained of strong acid taste and pain in pit of stomach. He was given every four hours one drachm of bicarbonate of soda in hot water and salines

[1] Purves: Edin. Med. Jour., March, 1902.

by rectum; kept in Fowler position. The vomiting continued until 3 o'clock next morning, when adrenalin chloride in 10 min. doses (sol 1 in 1000) was given by mouth every two hours. When this was commenced pulse was 112 per minute and very feeble; he was cold and sweating. The vomiting did not recur. Pulse-rate became normal and condition rapidly improved. When bowel acted on third day no melæna.

Shebbear, N. Devon.

A NOTE ON SOME SYMPTOMS FOLLOWING THE TAKING OF QUININE.

BY G. R. FOOTNER, M.B. CAMB., F.R.C.S. ENG.

THE statement occasionally made by patients that they cannot take quinine usually turns out an exaggeration, and the following example of quinine idiosyncrasy may therefore be of interest.

The patient, a young married lady, had lived for 11 years in British East Africa and had never suffered from malaria, though often exposed to infection. She had taken quinine twice. The first time a dose of 10 gr. by the mouth produced shortness of breath, œdema of eyelids, and urticaria. The second time similar but milder symptoms followed taking a drachm of Easton's syrup.

While going through the Sudan she had a severe attack of malaria on Dec. 24th, 1917, and the doctor gave, unknown to her, 5 gr. of quinine by the mouth. Great shortness of breath, œdema of eyelids, and urticaria occurred. Four grains were given by rectum; same result. After this no more quinine: fever slowly subsided. On the day after first dose of quinine (Dec. 24th) uterine hæmorrhage began and continued till Jan. 4th, 1918.

On Jan. 3rd no fever, no malarial parasites found in blood. After calcium chloride in daily dose of 30 gr. for two days quinine was given in ½ gr. doses three times a day for 24 hours and 1-gr. doses three times a day for 48 hours. After this two doses of 2 gr. each produced dyspnœa and itching of hands and feet. Amount reduced to 1 gr. thrice daily; fever recurred, subtertian parasites found. After 30 gr. of calcium chloride, ½-gr. doses of quinine were used hourly for ten doses, followed by 1 gr. hourly for four doses. This produced nausea, and three intramuscular injections, each of 7½ gr., were given in 24 hours. An urticarial rash appeared after second injection; no other bad effects.

Temperature now became normal and blood free of parasites. Before leaving Khartoum patient was taking 2 gr. of quinine thrice daily and received an intramuscular injection of 15 gr. with no ill-effects.

She was susceptible to the pollen of "black wattle," a kind of acacia found in British East Africa, but in England had never had "hay fever." Proximity to horses did not produce symptoms, and no other members of her family suffered. The symptoms were on all occasions witnessed by a doctor. The salt used was quinine bihydrochloride.

Khartoum, Sudan.

Medical Societies.

SOCIÉTÉ DE BIOLOGIE, PARIS.

THE following is a summary of the papers read at a meeting of this society on June 22nd:—

BRODIN, CHARLES RICHET, and ST. GIRONS.—Density of the Blood in Dogs.

En expérimentant sur 47 chiens normaux, pour déterminer les constantes en densité, en masse du sang, en hématies et en leucocytes, B., R., et G. font les constatations suivantes: l'élément le plus constant c'est la masse du sang; l'élément le plus variable, le leucocyte. La densité est proportionelle aux hématies.

H. CARDOT.—Density of the Blood after Hæmorrhage.

En suivant la variation de la densité sanguine au cours d'une série d'hémorragies successives, à la fois à l'aide des indications données par l'aéromètre et en déterminant l'extrait du sang, C. signale un notable abaissement de la densité dans ces conditions.

TRIBONDEAU.—New Blood Stains.

T. ajoute un nouveau colorant (colorant I) du genre May-Grünwald, de préparation très facile, au colorant simplifié genre Giemsa (colorant II) qu'il décrit récemment. En fixant les frottis avec ce colorant I, on obtient des colorations plus rapides avec le colorant II. Le colorant II était une solution alcaline d'éosinate de bleu de méthylène transformé par l'ammoniaque; le colorant I est une solution neutre d'éosinate de bleu de méthylène naturel.

E. SAQUEPEE.—A Small Epidemic of Alimentary Poisoning.

Petite épidémie (6 atteintes) d'empoisonnements alimentaires collectifs. Le *Bacillus enteritidis* est décélé dans les selles d'une part chez les malades, d'autre part chez un cuisinier demeuré indemne pendant l'épidémie. Mais le sérum du cuisinier, au 4e jour de l'épidémie est fortement agglutinant pour le *B. enteritidis;* au contraire, à cette date, le sérum des malades ne présente pas encore de propriétés agglutinantes, ces dernieres n'apparaissant que plus tard. De cette confrontation on peut conclure que le cuisinier a été en réalité malade quelques jours avant l'apparition de l'épidémie. Ce qu'il finit par avouer. Il a ensuite contaminé des aliments et provoqué l'épidémie.

HARDE and JACKSON.—Tolerance Acquired by Staphylococci towards Antiseptics.

Il résulte des expériences de H. and J. qu'il ne s'agit pas d'une loi générale et que l'accoutumance du staphylocoque, par exemple, facile à obtenir vis à vis de l'acide phénique, ne s'obtient nullement, ni *in vitro*, ni *in vivo*, vis à vis de la solution de Carrel-Dakin, dans laquelle l'action antiseptique est exercée par l'hypochlorite de soude. Cette remarque offre un interêt au point de vue du traitement des plaies infectées.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

(1) STANNOXYL, AND (2) KINECTINE.

(ANGLO-FRENCH DRUG CO., LTD., GAMAGE BUILDING, HOLBORN, E.C. 1.)

1. THE observation that tin-workers were apparently immune from boils has led to the elaboration of metallic tin preparations containing the oxide as well as the lead-free metal for the treatment of furunculosis. Such is stannoxyl, presented for administration in the form of greyish-coloured tablets. The treatment is empirical, but the clinical cases reported certainly call for attention on account of the favourable results obtained in skin eruptions which are staphylococcal in origin. This is supported by a series of cases in a paper by Dr. A. Compton, published in THE LANCET.[1] So far the method has been tried in the treatment of carbuncles, boils, anthrax, acne, and styes. Our laboratory examination confirmed the absence of lead in the stannoxyl tablets submitted to us.

2. Kinectine is a somewhat complicated compound having quinine as a pharmacological basis. It is, in fact, a combination of hectine (sodii-benzo-sulpho-*p*-amino-phenyl arsenas) with quinine hydrochlorate. It has been reported, chiefly in French clinics, as a specific in the treatment of hay fever, malaria, and influenza. This combination of quinine with an organic arsenic group is of interest.

COFFEE PERLETTES.

(GILTSPUR CO., LTD., 33 AND 35, EASTCHEAP, LONDON, E.C. 3.)

It is not in our experience that the so-called coffee essences (fluid) satisfactorily replace the well-made infusion of the ground and fresh-roasted coffee berry. This is probably in a large measure due to the lack of freshness of such preparations. These coffee perlettes, however, appear to retain the aroma and fragrance of coffee because they represent a well-prepared extract or infusion subsequently reduced to the dry solid state; they are moulded into rounded particles which look like the roasted berry in miniature. These are readily soluble in hot water and the solution approaches more closely the attractive characteristics of the freshly prepared infusion than any essence or extract we have examined. According to our analysis, the pure coffee perlettes contained as much as 5·16 per cent. of their weight of caffeine, so that, calculated on this basis, the preparation represents about five times its weight of coffee, since the berry contains 1 per cent. of caffeine. The moisture amounted to only 2·80 per cent., and the mineral matter is 14·5 per cent., consisting chiefly of potash salts. The perlettes made with the addition of some chicory gave similar results. For the extemporaneous preparation of a quite good cup of coffee these granules will be found convenient, and they are also economical in use, since they are free from "grounds." The composition of the fluid extracts of coffee upon the market formed the basis of a report from THE LANCET Laboratory published in our issue of July 7th, 1894, p. 43. Twelve specimens in all were examined, and the general result was to show a deficiency of caffeine, due probably to the deposition of this alkaloid as insoluble tannate in the course of manufacture.

COLLOSOL CUPRUM.

(THE CROOKES' LABORATORIES, 50, ELGIN-CRESCENT, LONDON, W. 11.)

Colloidal copper has recently received attention in regard to its application in malignant disease, the view being held that under a favourable environment it serves as a carrier of oxygen. However this may be, certain interesting results have been recorded as to colloidal copper restraining the growth of embryonic cells. We have received specimens of ampoules of collosol cuprum for intramuscular or subcutaneous injection, and pessaries and suppositories for local treatment containing this agent. The fluid in the ampoules is of a brownish-red colour and does not respond to the ordinary reaction of crystalloid copper until the colloidal condition is broken up. The application of catalytic agents in the treatment of disease undoubtedly promises interesting development with further study.

[1] THE LANCET, 1918, i., 99, 143.

THE LANCET.

LONDON: SATURDAY, JULY 6, 1918.

Belgian Doctors' and Pharmacists' Relief Fund.

WE appeal this week jointly with our important contemporaries, the *British Medical Journal* and the *Pharmaceutical Journal and Pharmacist*, for further and immediate support for the Belgian Doctors' and Pharmacists' Relief Fund. At the close of 1914 the Fund was started by an appeal emanating from a committee fully representative of the medical and pharmaceutical professions in Great Britain and Ireland, and as a result about £20,000 were received almost entirely from members of those professions, the contributions from the colonies and India being conspicuous in the total. Support was also received from the United States of America, but it must be remembered that ever since the war began relief of the most generous kind has been afforded to the whole population of Belgium by the United States through the Commission for Relief in Belgium, and in this relief the professions with which we are immediately concerned have had, and are having, their share. At the beginning of the movement the money collected by the Committee of the Belgian Doctors' and Pharmacists' Relief Fund was spent in relieving distress among the members of the medical and pharmaceutical professions, being Belgians, who had taken shelter in this country, often accompanied by a considerable number of dependents. Through the representations made by the Committee, and through the personal work of the officers and the whole-hearted devotion of Dr. DES VŒUX, the honorary treasurer, the needs of the immigrant refugees were speedily met. Sums of money as grants, or as weekly allowances for a period, were provided in certain directions; employment was obtained in other cases. By the help of advertisement medical posts were found both for the Belgian doctors and Belgian pharmacists; and, the General Medical Council having admitted Belgian doctors of approved standing to the Medical Register of the United Kingdom, the necessary registration fees for those doctors were paid by the Fund. In this way, both with promptitude and with no large cost to the Fund, the refugees on our shores were succoured, while in time a good many of the Belgian medical men joined up with their national army.

But in the meantime the hand of Germany grew heavier and heavier upon the outraged Belgian land, when it was learned through Mr. C. HOOVER, then the Director for Europe of the Commission for Relief in Belgium, that it would be possible for the Fund to supply the Belgian doctors and pharmacists remaining in their own country with material assistance in money and drugs. He undertook the forwarding to safe hands of any subsidies sent to him by the Fund. The machinery for disbursing the money was provided by a representative committee of Belgian doctors and pharmacists sitting regularly in Brussels; and through Mr. HOOVER, since March, 1916, up to December, 1917, £800 were sent regularly every month to this Belgian committee for allocation among the doctors and pharmacists of Belgium. When this policy of regular disbursement was embarked upon it was easy for the Executive Committee of the Belgian Doctors' and Pharmacists' Relief Fund to fix the date by which their resources would be exhausted, that date being the end of 1917. There was a general belief that actual military operations would have come to an end by that date; but, alas, the Fund reached the bottom of its purse while the war remained in full blast.

At the beginning of this year it was determined by the Executive Committee that a second appeal should be made to enable the Fund to continue its work, and, at the time when the appeal was issued, only sufficient money remained to warrant the sending of £400 in the months of January and February; and this was the more bitterly disappointing to the committee in that, at the end of 1917, a representation was received from the

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

AN APPEAL

TO ALL MEMBERS OF THE MEDICAL AND PHARMACEUTICAL PROFESSIONS

In 1914, by resisting Germany, ***Belgium saved you*** *from starvation and ruin.*

In 1915 you honourably responded to an appeal by subscribing a fund for your Belgian colleagues in their distress.

During 1915, 1916, and 1917 this money was sent in instalments to Brussels—at first £800 per month, later £400. The Fund is now exhausted, all but £700.

In 1918 will you leave your Belgian colleagues to starve?

Subscriptions may be sent to the Honorary Treasurer, Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W. 1

Commission for Relief in Belgium, through Mr. W. B. POLAND, who had succeeded Mr. HOOVER, to the effect that never was the money and the moral support more urgently required in Belgium by our suffering colleagues. Mr. POLAND wrote:—

"The most difficult class to reach is the very class that your Fund in the past has ministered unto—namely, the families of the doctors and pharmacists who may not dig, to beg they are ashamed. If the supporters of your Fund knew how much actual suffering they had allayed, and how much potential moral and physical suffering they had prevented, they would not cease to continue their support, many as are the claims now made upon them. ..... The people who receive your kindness and charity are grateful in the extreme. Wave after wave of gratitude sweeps over the country. Some day you will know of it. ..... The funds from your society are paid over to a commission of eminent gentlemen of your profession, and the distribution is under their personal supervision. The knowledge that their associates in England have not forgotten them is an inspiration to the whole profession at a time when moral support is perhaps as much needed even as food."

In view of this communication a general meeting of the Fund was held, a second appeal was issued, and the result of that appeal has been announced weekly in the medical and pharmaceutical journals. All our readers, therefore, know that, generous as the individual response to the second appeal has been in a certain number of instances, no general support of the movement was secured thereby. As a matter of fact, to-day the Executive Committee of the Fund is in much the same position that it was at the beginning of the year. Enough money remains to pay one more mensuality at the reduced rate of £400, and then, despite the moving cry of anguish and gratitude from our colleagues in Belgium, the subsidies must cease. We earnestly entreat our readers to do their utmost to avoid this miserable situation. A general and generous response to the request for subscriptions made now should enable the Fund to continue its sorely needed work until the end of the war.

We know what we are asking. From hard-worked professional men, many of whom are themselves pecuniary sufferers by the war, and all of whom are weighed down by the burdens of increased taxation and heightened expenditure, we are begging for money which they sorely need themselves and for which a dozen other admirable sources of expenditure present themselves. But we cannot conceive any more worthy object than the assistance of our Belgian colleagues. In the words of the chairman of the Fund, Sir RICKMAN GODLEE, in our columns last week—"it is to pay a debt which we owe to our hardly entreated brethren." The need of our Belgian colleagues is indescribable, and the national action and character which have brought them to this condition are beyond all praise. With measureless gallantry the Belgians faced and held up the German onrush, and in those first eventful weeks of the war saved Paris and France, saved the Channel ports and England—and ruined themselves. They preferred ruin to dishonour, and it is the bounden duty of all of us, remembering this fact, and recognising not only its moral grandeur but its practical benefits to ourselves, to do all in our power to alleviate their misery until the day of deliverance, now approaching, finally arrives.

Lessons from Baby Week.

LAST year National Baby Week was devoted primarily to propaganda work; the week which has just passed has been chiefly of an educational nature. By a strange paradox, during the fourth year of war much has been done to direct public attention to the value of infant life. Unification of effort is being achieved in this and other countries, emphasised by the visit to this country of such striking child-welfare advocates as Judge NEIL, of Chicago, Dr. W. PALMER LUCAS, of the American Red Cross, and Dr. F. TRUBY KING, of New Zealand. Many of the leading home agencies for the care of mother and child have combined in a National League for Health, Maternity, and Child Welfare and the new and influential Council for the Unmarried Mother and her Child was represented unofficially at the Baby Week inauguration. This being so, the arrangements for the London Week centred round a series of conferences and didactic lectures held within sight of an exhibition arranged by Mrs. OGILVIE GORDON, D.Sc., to show the thread connecting all kinds of child-welfare effort. More, probably much more, remains to be done in order to make an exhibition of this kind accord with the present level of exact knowledge, while still arresting public attention. The sections devoted to venereal disease and to the question of heredity were happier in achieving this than that devoted to alcohol. In general, the conception of fatherhood appeared again rather strangely absent from the exhibition, giving point to Mr. BEN TILLETT'S remark at the inaugural ceremony that although we required all the mothers we might easily do with half as many fathers.

The educational aspect of the child-welfare question is dealt with in a broad way by two writers in our present issue. Sir ARTHUR NEWSHOLME combats the prevailing ignorance of the elements of public health in an address recently given at a conference of sanitary authorities in the county of Durham. What the Bishop of BIRMINGHAM described at the Baby Week meeting as the Kingdom of Heaven on earth would be realised easily enough if we could start afresh with new materials, but the substructure of that Kingdom in Durham county is characterised at present by extremely filthy domestic arrangements. Sir ARTHUR NEWSHOLME shows that a thousand infantile deaths occur each year in the county which would have been saved if Durham shared even the mediocre average experience of the rest of the country. His remarks are primarily addressed to Durham authorities, but that no one elsewhere may glory in his superiority Sir ARTHUR NEWSHOLME states that in every area "pockets" may be found which form death-traps for the infants living in them. He asks whether any of us could live healthy lives in houses possessing no larder and no sink, and a malodorous ashpit and privy in the back-yard. Some of us with higher ideals and greater initiative may be inclined to reply that we could, possibly forgetting that the deplorable sanitary conditions described destroy

not merely physical health but any desire for betterment on the part of their occupants. Sir ARTHUR NEWSHOLME fairly claims for his address that it makes less venial the ignorance of town councillors and property owners in regard to the importance of local hygiene.

Dr. H. W. POOLER'S article is also a plea for education, but for education of a different and more definite kind His paper is a closely reasoned reply to a report published by the Medical Research Committee, which found that in the child-welfare movement educational methods were subsidiary to the clearing of slum areas and the abatement of smoke pollution. He stands for the consensus of opinion represented by 20 years' increasing and strenuous work for the education of the mother and the improvement of the home. House-to-house visitation by trained municipal and voluntary visitors has, as he rightly says, become the rule during this time in almost every town and county in the kingdom, and the Local Government Board has recently stiffened its demand in regard to the proportion of health visitors to notified births. One to four hundred is now the authorised standard. Has all this vast work to be unconditionally scrapped, Dr. POOLER pointedly asks; and we commend the careful attention of our readers to his reasons for finding the conclusions of Dr. W. A. BREND and Dr. LEONARD FINDLAY to be ill-grounded. With regard to the relative ignorance of urban and rural mothers Dr. POOLER speaks with the authority of experience, and taking ignorance of mothercraft in the broadest sense he asserts without hesitation that the infants of the agricultural classes are far better off than those in the towns. For, he says, "mothercraft" means carefulness, personal cleanliness, clean bedding, clean floors, proper storage and preparation of food, frugality, thrift, sobriety, early hours, and, above all, breast-feeding; and the opportunities for all these things the country woman possesses to far greater extent than her sister in the slums. The Research Committee's report was in large measure a plea not to lose sight of the wood—i.e., not to neglect the broader issues of public hygiene in the pursuit of its personal and private applications—for the trees which compose it. Dr. POOLER reminds us that the wood is made up of trees and that there is much accumulation of undergrowth to be removed, and we are in hearty accord with his conclusion that in the careful local consideration of local conditions the problem will be solved. No panacea has been or will be found. A central guiding Ministry of Health may help; the Local Government Board's "fertilising grants" will also help; but neither will avail without an influx of knowledge permeating down to the worker and the mother.

Sir Bertrand Dawson not being able to deal sufficiently exhaustively in one lecture with the subject "The Future of the Medical Profession" in the Cavendish lecture at the West London Hospital, will deliver a continuation of the lecture on Thursday next, July 11th, at the Royal Society of Medicine at 8.15 P.M., when a discussion will follow, whereat the views of all interested will be welcomed.

Annotations.

"Ne quid nimis."

PHYSICAL DISABILITY AND PUBLIC SAFETY.

THE problems of conduct presented to the medical profession as a result of the clash of the duty of professional secrecy with the duty of care for the interests of others have often enough been discussed. A correspondent sends us for criticism a modern instance as met with in the work of the medical recruiting boards of the Ministry of National Service.

These bodies have recently, and in great numbers, had before them for medical examination men of mature age, and men who for one reason or another have not volunteered for military duty. Such recruits are, of course, of low physical efficiency, generally speaking, and will naturally present a large amount of disease and defect, disabilities which, on the one hand, the prospect of military service may make them communicative about, and amongst which (on the other) are sometimes now coming to light such as, if known to employers, or, indeed, to fellow employees, would entail dismissal, being plainly incompatible with the safety of others, sometimes of very many others, if not of their own as well. Medical boards have found here and there anomalies like colour-blind signalmen, epileptics in charge of colliery lift apparatus, syphilitic glass-blowers, these gross physical disabilities having been previously concealed by their subjects through carelessness or self-interest. It is said, too, that requests by the presidents of boards for instructions as to possible action in view of the menace to public safety have not been answered in a positive sense. Hard as the saying "do nothing" may seem, it yet does apply in many cases where the relation between medical examiner and examinee is the ordinary one between physician and patient. But the instance under question seems of a different complexion, for here the relation in question is public, not private, is brief and casual, not intimate and confidential. There is no "cash nexus"; while, it might be added, the present is a time when any man in any degree able-bodied can find employment somewhere, and when public health and welfare need conserving as never before. As a matter of practical politics, would it not be better to remove the individuals alluded to from their dangerous posts and compensate them rather than run the continual risk entailed by the plan of leaving ill alone?

The point raised is one of interest to the public as well as to the medical profession, but the situation, as matters stand, is fairly clear. The medical practitioner who ascertains the physical condition of a proposed recruit is working as a servant of the Crown under the instructions of a Government department, and the man whom he examines presents himself under orders in like manner. No relation exists such as that between a medical attendant and his patient, and there is no question of ethical obligation in such publication of the physical condition of the person examined as may arise out of work done for the recruiting board. It is quite different, however, when it is proposed to make known to employers conditions in a workman which may render him unfit for his employment. To do this in the present circumstances would hardly be justifiable ethically; it might quite possibly constitute a breach of the Official Secrets Act, and any such action taken independently of official authority might render those responsible for it the object of litigation at the hands of the person reported upon. This, however, is hardly what is proposed, the suggestion being, as we understand it, that official reports should be made to employers as to conditions which render continued employment of a workman undesirable. No doubt such reports, if they could be made upon the authority of medical men gaining knowledge through the discharge of duties primarily connected with recruiting, would in an appreciable

number of cases be advantageous to the workmen in contact with the person reported upon and to the public. The extent of that advantage would, however, probably have to be established with reasonable certainty before the Government would move in the matter, and it seems likely that an Act of Parliament would be necessary in order to ensure complete safety for all those connected with the passing on of information obtained for a particular purpose, with a view to use being made of it for purposes wholly disconnected from the first.

META-INFECTIVE FEVERS.

UNDER this heading Professor Umberto Baccarani, in *La Riforma Medica* of March 16th, calls attention to the fact that patients, subsequently to acute febrile diseases, not infrequently develop after a few days of complete apyrexia, a subfebrile condition which is not easy to account for. These processes are of variable duration and uncertain course, their pathology is different in different cases and often puzzling to explain. It is necessary, in the first place, to exclude from this category relapses and reinfections of the primary processes, and complications attended by febrile manifestations of evident origin and easy interpretation. True meta-infective fevers may be the only manifest expression of a slight and temporary complication of the previous acute disease or may have their origin in the flaring up of some morbid condition not previously recognised, or depend on some unusual complication which has no relation to the preceding infection. But in other cases the meta-infective fever is cryptogenetic or essential in the sense that its real cause remains obscure in spite of the most diligent investigation and laboratory research. When, therefore, a patient in an apparently well-established state of convalescence has a rise of temperature from causes which otherwise are not capable of raising it, the implication is that we have some potential morbid condition which should be thoroughly investigated. Such meta-infective fevers usually make their appearance a few days after the cessation of the illness, from three days to a week. After this period the occurrence of fever cannot be classified under this appellation, since it almost invariably points to a true and recognised complication of easy diagnosis and special characteristics. Their duration is short, not usually more than a week, their form and course strikingly variable, and their intensity moderate, the temperature ranging from 37° to 38° C. Professor Baccarani's clinical observations have led him to attribute the cause of these meta-infective fevers to the following conditions:—

1. A simple follicular colitis, usually concomitant with a return to more substantial diet and associated with slight abdominal pain and distension, loose stools, or constipation. The condition disappears rapidly on a return to milk diet. 2. A mild appendicitis with absence of any prominent symptoms at the time, but which becomes evident by subsequent events. 3. Cholecystitis, most often after a typhoid infection. 4. Pyelitis and cystitis, revealed by examination of the urinary sediment, and especially frequent after typhoid and paratyphoid infections. 5. Endocarditis of a benign type. 6. Slight localised pleurisies. 7. Osteomyelitis of mild type, the only symptom being an aching and tenderness in the lower third of the thigh; this cause is most frequently met with in young adults and children. 8. Crypto-bacillary fever—tubercular, malarial, or syphilitic. 9. Adenoids. 10. Diseases of the female genital system. 11. Slight inflammatory conditions of the skin or subcutaneous tissue caused by hypodermic injections of camphorated oil.

Professor Baccarani's observations are singularly interesting and suggestive. The interaction of morbid processes is a subject which has as yet not attracted the attention it merits. The occurrence of febrile or subfebrile conditions during convalescence is very frequently observed, and is too often disregarded or looked upon as a mere incident in convalescence. We hope that Professor Baccarani's paper will lead to a more scientific analysis of these conditions in this country. It is more than probable that research on these lines might lead to some valuable results both in pathology and treatment.

THE SUPPLY OF "MARYLEBONE CREAM."

DIFFICULTIES in connexion with the supply of cream for infant feeding have created a great demand for substitute fats, and an enormous quantity of specially prepared emulsion of linseed oil, known popularly as "Marylebone cream," has been supplied to welfare centres. Unfortunately, the supply of linseed oil available for this purpose is rapidly becoming exhausted. We understand, however, that one at least of the large wholesale firms which supply Marylebone cream has made application to the Food Controller for the release of a sufficient quantity of this oil to satisfy the requirements of welfare centres, urging as a plea that its use for this purpose is of national importance. We hope that the Ministry of Food will take a favourable view of the application, as deprivation of a physiological supply of fat is a serious cause of malnutrition among the infants of the poorer classes, and linseed oil is one of the cheapest forms in which fat can be supplied, while experience goes to prove that it gives excellent results when used judiciously.

REGISTRATION OF NURSES.

TWO important meetings of nurses have recently been held, at both of which the question of registration was to the front. The conference organised by the College of Nursing, Ltd. (by guarantee), was of a more general character, dealing in successive sessions with the higher education of nurses, with the preliminary course of training for probationers, and with reconstruction in nursing ideals and practice. The attendance at this conference was large and the discussions of a free and helpful character. At two sessions medical men occupied the chair, and both medical men and women contributed to the discussion. The other meeting was the annual gathering of the Society for the State Registration of Trained Nurses, and this meeting dealt more exclusively with the immediate and pressing question of the adoption by Parliament of the Registration Bill. Major W. A. Chapple, who is in charge of a Nurses' Registration Bill, stated that he had been in communication with the College of Nursing and could come to an agreement whereby two-thirds of the electorate of the proposed Nursing Council should be nurses. In addition to this, he said that it could be agreed in the Bill that two-thirds of the actual Council should be nurses. These two things, he thought, were sufficient to ensure the principle of the government of nurses by nurses, and therewith the economical independence of the worker on which every profession now lays stress, and Major Chapple himself is prepared to assist in an agreed Bill upon these lines. We welcome an assurance made by Mrs. Bedford Fenwick from the chair, speaking on behalf of the

Society for the State Registration of Trained Nurses, that the society has never been obstructionist; and now is evidently the time to give practical proof of this. A resolution was passed at the annual meeting of the Society for the State Registration of Trained Nurses, and sent up to the Central Committee for State Registration, which contained a clause dissociating the society from the College of Nursing. The affirmative vote was by no means a large one, but an amendment to secure freedom from "the domination" of the College of Nursing, "without dissociation from it," was not accepted by the chair. We find this attitude hard to distinguish from obstruction. We have every confidence in the ability of nurses to settle their own polity without help from outside, but the statement of a speaker at the second meeting already referred to, that nurses had made up their minds decades ago and resented the butting-in at the end of a new group, may make even the sympathetic outside observer a little anxious in regard to a wise and just settlement. It is, after all, the present and the future of the nurse that really matter, and the past—like other pasts—may well be buried. Nothing is more certain than that the profession of nursing is likely to undergo profound changes within the next few years, and provided that it is placed in a position to manage its own affairs plasticity is altogether desirable. A new vista of public health work has already opened before the nurse in America, where she is acquiring a position of usefulness and importance in relation to the maintenance of health rather than to the treatment of developed disease. Conditions of training in this country need to be widely modified before the nurse is fitted for this. The present hospital routine disciplines the nurse rather than trains her. Unless possessed of superhuman powers, the nurse throughout her training course is too fatigued by her routine ward duties to think or read of anything outside them. The training becomes largely one of patience, endurance, and self-sacrifice. Essential though these traditional virtues are, the community could forgo some part of them in favour of a more thoughtful and intelligent health agency. In the change just introduced by University College Hospital, London, where an eight-hours day for nurses has practically been adopted, we see the beginning of better things. Moreover, it is impossible for us to believe that the nurse will not wish to take her share in the great wave of infant welfare activity now sweeping over the country, from which the tendency is at present to exclude her on account of the onesidedness of her training.

WE deeply regret to announce the death of Viscount Rhondda, which occurred on Wednesday morning last, at the age of 62. To Lord Rhondda's courage, energy, and resourcefulness this country owes an incalculable debt.

Colonel William Hunter will give a lecture on the Prevention and Arrest of Lice-borne Diseases at the Royal Society of Medicine, at 5.30 P.M. on Wednesday, July 17th. As president for two years of the advisory committee for the prevention of epidemic diseases in the Eastern war areas, and colonel in charge of the British Military Mission to Serbia in 1915, Colonel Hunter has had exceptional opportunities of practical experience in the new methods of disinfection. The lecture will be accompanied by lantern demonstration and is open to any member of the medical profession.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions and donations to the Fund have been received during the week ending June 29th:—

	£	s.	d.
The Right Hon. T. R. Ferens, M.P.*	21	0	0
The Right Hon. Lord Leverhulme*	10	0	0
Dr. A. B. Kingsford ...	1	1	0
Mr. F. Ransom†	10	0	0
Sir Rickman Godlee ...	2	2	0
The Lady Betty Leslie Melville‡	50	0	0
Dr. Thos. Wingrave ...	1	1	0
Sir Anderson Critchett	5	0	0
Dr. F. R. Proctor-Sims	1	1	0
Dr. M. M. Bowlan	3	3	0
Dr. Norman Walker ...	10	10	0
Dr. Wherry Wilson ...	1	1	0
Dr. A. H. F. Barbour ...	25	0	0
Dr. T. Steele Sheldon ...	1	1	0
Dr. H. G. Turney	3	3	0
Dr. H. Lyon-Smith ...	5	5	0
Dr. A. H. Copeman ...	5	5	0
Dr. Victor Philippe ...	1	1	0
Dr. Hervey Bodman ...	5	0	0
Lt.-Col E. Le Cronier Lancaster, R.A.M.C....	2	2	0
"R."	2	0	0
Dr. M. Black Jones ...	2	2	0
Sir Alfred Pearce Gould (monthly)	5	0	0
Dr. E. Farquhar Buzzard	5	5	0
Mr. and Mrs. Herbert Tilley	15	15	0

* Per Sir Thos. Barlow. † Per Sir Rickman Godlee.
‡ Per Dr. Des Vœux.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

MEETINGS OF THE EXECUTIVE COMMITTEE.

A meeting of the Executive Committee was held at the offices of THE LANCET on Wednesday, June 19th, when a letter was read from the Commission for Relief in Belgium (C.R.B.) stating that the subsidies of the Fund were always received by those for whom they were intended, and were of enormous value and moral support. In the letter was enclosed a long statement from the Belgian Commission Mixte sitting in Brussels, which proved the dire need of the Belgian medical and pharmaceutical profession of drugs, the careful steps taken to distribute to the best advantage their supplies, and their dread of a failure of those supplies.

Dr. DES VŒUX stated that the Fund had now only £600 to its credit, and that a further subsidy was due to the Belgian Committee at Brussels in July, which meant the virtual end of the Fund unless appeals to the medical profession proved more fruitful. He commented on the fact that the Fund was very poorly supported by the leading members of the medical profession. He said that the second appeal had brought in £1100 5*s*. before the issue of the circular letter and £1156 since, but added that £400 of that money had been given in response to personal appeals to friends made by the chairman and himself.

Dr. HERBERT SPENCER said that, judging from, among other things, the attitude of the Fellows at a recent Comitia of the Royal College of Physicians of London, the profession did not believe that the money reached its destination in Brussels, but was chiefly distributed among the Belgian doctors in this country; and several members of the Committee agreed that this was a prevalent feeling despite the categorical statement to the contrary repeated in the medical and pharmaceutical press.

In a debate on the course to be pursued to raise more money, in which every member of the Committee took part, it was agreed that for the present the appeal should be made to medical men and pharmacists only, but that they should be asked to bring the urgent need of the Fund before their personal friends.

A meeting of the Executive Committee was held on Monday, July 1st, at the offices of THE LANCET, when Dr. Des Vœux reported that the letter from Sir Rickman Godlee, published in the *British Medical Journal* and *The Lancet* the previous week, and urging members of the medical profession to support the Fund, had produced good results. The publication in the *Pharmaceutical Journal* of excerpts from the statement of the Commission Mixte (see below) had been very serviceable. The mensuality of £400 for July would be sent off.

An Urgent Appeal from Belgium for Immediate Assistance: A Guarantee that the Relief Reaches the Distressed Classes.

The following passages from a communication addressed to Dr. S. Squire Sprigge, Honorary Secretary to the Fund, by Mr. Lewis Richards, the Assistant Director of the C.R.B.,

speak eloquently as to the imperative need for further substantial succour of our hapless professional brethren in Belgium :—

"I need hardly remark that the charities thus in receipt of subsidies through our channels are most carefully administered, and there is no possibility of any leakage on the way. I would like, however, to repeat—nor can we emphasise this point too strongly—that the need of help for Belgium grows with every day, and the reports which we receive from all branches of the work are nothing short of heart-rending. In this connexion we think you will be interested in reading an appeal which we recently received from a commission of doctors in Belgium asking for various medicines. You will see from this letter [the appeal of the Commission Mixte—see below] the difficulties against which the medical profession in all its branches has to contend."

"Your Fund is one which reaches a class which cannot be helped in any other way. For the most part the professional men are too proud to come to the public soup-kitchens, and after four years of terrible privation any little savings which they may have had are by now exhausted. But they will and do most gratefully receive help from your Fund, and with the assistance thus given them goes a most comforting feeling that their happier colleagues overseas are not forgetting them—a feeling which brings moral support, as the money brings them material comfort."

The Grave Need for Drugs.

The communication from the Comité National des Secours et d'Alimentation (Commission Mixte des Médicaments, Brussels), addressed to the Director in Europe of the C.R B., is the document alluded to in Mr. Richards's letter. It is signed by M. Herlant, pharmacien and D.Sc., professor at the Free University of Brussels, and M. Coelst, pharmacien, echevin of the commune of Laeken, as well as by Dr. Pechère, Dr. Herman, and M. Meunier, the secretary. It is a clamant appeal for the despatch to Belgium of supplies of chemical and vegetable drugs, of which there is a total lack. The dearth is such that many practitioners have to resort to inferior alternatives, and many antiseptics are practically unobtainable, so that in the event of an epidemic the situation would be of unheard-of horror. The drugs distributed by the Commission are also supplied to the middle classes, who are grievously impoverished, and as a consequence of innutrition or malnutrition the whole population is seriously enfeebled, and is therefore consuming a larger and larger amount of tonic and fortifying drugs. In order to cope with these adverse circumstances the Comité National has organised a Medical Secours and Pharmaceutical Secours. Medical cards are issued, and the medicines prescribed by 2000 doctors united for the service are dispensed by 1500 chemists throughout the country at a uniform rate, and the Comité pays the bill, which averages 1,500,000 francs monthly. In Brussels there is a Central Pharmacy, under the control and administration of the Comité, which manufactures and distributes the large bulk of the standard pharmaceutical products to doctors and chemists, and also undertakes dispensing. In less than two years it has dispensed 250,000 prescriptions, and by means of statistical analysis of the drugs used in these prescriptions and those issued through the Medical Secours the Comité can determine what quantities of the drugs commonly prescribed are essential for the maintenance of the pharmaceutical service for one year.

Special attention has been directed by the *Pharmaceutical Journal* to the statement in the closing passages in this document, which ought once for all to allay the suspicion that the money or goods destined for the relief of Belgian doctors and pharmacists and of the general population in Belgium get into the wrong hands or are improperly administered :—

"The Commission Mixte, which the C.N. has specially created to assure the distribution and control of medical supplies which it manufactures or imports, can give the assurance that the drugs imported will never give rise, under its dispensation, either to smuggling or to abuses. They are in a position, without commercial interference, to send them direct to the hospitals, to the 1500 chemists' shops of the country, to the 500 doctors holding office, according to the real needs of each one, needs which are determined according to a rationing of indigenous products in use for more than two years, and which, up to the present, has given every satisfaction to the services of control instituted by the Comité National.

"The Commission Mixte would be happy to be able to convince the C.R.B. of the absolute necessity of immediate intervention. The profession, the larger hospitals, the official Medical Commission, all those who in this country have a practice, a post, or a responsibility, are conscious of the danger, and send us constant expressions of alarm. We will be glad to believe that the C.R.B. will not neglect any means by which it can be avoided that to all the sorrows, inevitable sufferings, should be added for our enfeebled and anæmic populations the terrible prospect of even worse days to come, when to moral tortures shall be joined physical sufferings which it will be in no man's power to alleviate or to cure.

Similar assurance has been regularly given by the *British Medical Journal*, the *Pharmaceutical Journal*, and *The Lancet* that the money subscribed invariably reaches the Belgian sufferers in that country, and that the benefits derived from it are allocated with scrupulous care.

THE FUTURE OF THE INDIAN MEDICAL SERVICE:

DEPUTATION FROM THE BRITISH MEDICAL ASSOCIATION TO THE SECRETARY OF STATE FOR INDIA.

A DEPUTATION from the British Medical Association met the Secretary of State for India, the Right Hon. E. S. MONTAGU, M.P., on June 27th, to discuss the present conditions and the future of the Indian Medical Service.

In introducing the deputation, Sir CLIFFORD ALLBUTT expressed the general feeling that the I.M.S. is not so attractive as it might be to the young medical man, mentioning as a deterrent the absence of opportunities for research. Lieutenant-Colonel R. H. ELLIOTT, I.M.S., alluded to the reasons which made the I.M.S. at the present time "the despair of British medical schools." Financial stress, constant supersession by junior officers of other branches, and interference with retirement, were some of the points he mentioned. Sir BERKELEY MOYNIHAN spoke of what he considered the progressive deterioration in the qualities of the Service, and pressed for reform in the substitution of a single Royal Indian Medical Corps for the two corps at present serving in India, for increase of pay, and for the right of private practice. Dr. J. NEAL, speaking as deputy medical secretary of the B.M.A., desired the Government to know the extent of the discontent existing among the officers of the Service. Dr. DAWSON WILLIAMS compared the cream of men entering the I.M.S. in his own early days with the deteriorated tone, changed outlook, and discouragement of the present service. Surgeon-General P. H. BENSON, I.M.S., concluded with an expression of regret that the Service had no direct access to the Council or Governor.

Mr. MONTAGU then read a comprehensive reply to the deputation, recalling his own medical study and giving his personal views on a policy which he intended to see through. He agreed with the apprehension felt at the very unsatisfactory state of affairs. He desired himself to consider the whole question as one of doing something for India by insuring a supply of good doctors. In regard to what had already been done he said :—

"We have improved the rates of staff pay in the field; we have developed a scheme of accelerated and acting promotion to prevent supersession of I.M.S. officers by officers of the R.A.M.C.; and finally we have made promotions in the place of officers who have had to be retained beyond the normal limit. In addition two temporary surgeons-general have recently been appointed to meet the special needs of the war."

Mr. Montagu went on to lay down the following four governing principles to guide future action :—

1. To ensure for the I.M.S. suitable opportunities of interesting practice, wide experience in the cure and prevention of disease, and the retention of private practice in so far as it did not interfere with the efficient discharge of public duty. The indigenous medical profession should, he thought, grow up in an atmosphere of free competition with highly trained European doctors.

2. To revise the present inadequate pay and emolument of the I.M.S., for which the introduction of the station hospital system afforded opportunity of reconsidering. Sufficient periodic leave must be available for Europeans serving in India.

3. To provide increased opportunity for Indians to enter the I.M.S. on equal conditions and with equal opportunities of promotion, and to extend medical education in India.

4. To remove sources of friction in the service at present producing great unhappiness. The two services in India must, he said, be considered together with a view to achieving unification.

Mr. Montagu concluded by an expression of agreement with the deputation in regard to the training of all members of the services in the diseases of women and children, and of the provision of facilities for research, stating that the Viceroy was determined to provide for India the medical assistance needed by the Empire.

EPSOM COLLEGE.

Annual General Meeting.

Sir HENRY MORRIS, the treasurer, presided at the annual general meeting of the Governors of Epsom College on Friday last, June 28th, at Soho-square.

The SECRETARY submitted the report of the scrutineers and mentioned that as two further vacancies for pensionerships had occurred the Council would admit at their meeting immediately after the annual general meeting the first two unsuccessful candidates—namely, Mrs. Lydia A. B. Clark and Mrs. Emily Archer.

Successful Candidates.

Seal, Arthur M. B. ...	4,953

† Ordinary pensioners.

In submitting the annual report for the past year the CHAIRMAN drew attention to the establishment in perpetuity of four Entrance Salomons Scholarships of £50 a year each and three Leaving Salomons Scholarships of £100 a year each. These scholarships, he said, had been established as a result of a grant of £10,000 by the committee appointed under the will of the late Mr. Leopold Salomons to distribute his residuary estate, the award having been made "as a slight recognition of the splendid work of the medical profession carried on during the war." The Chairman also drew attention to the War Memorial Fund for rebuilding the nave of the chapel in harmony with the new chancel, wherein a suitable monument could be placed bearing the names of Old Epsomians and Epsom masters fallen in the war. At present, he said, there were over 700 Old Epsomians serving with the forces, of whom 600 had joined since the outbreak of war. In the Roll of Honour of Old Epsomians were included 75 who had been killed in action, 4 who had died in hospital, 7 accidentally killed, 10 who had died of wounds, 120 who had been wounded, 6 who were missing, and 5 who were prisoners. Fifty-eight Old Epsomians had been mentioned in despatches, 1 five times, 2 four times, 2 three times, and 4 twice; 1 had been awarded the Victoria Cross (Brigade-General R. B. Bradford, since killed), 7 the Distinguished Service Order (2 with additional bars), 1 the Distinguished Service Cross, 47 the Military Cross, and 1 the Croix de Guerre.

The report was adopted, but certain paragraphs therein, reflecting upon the attitude of the Royal Medical Bevevolent Fund, were made the subject of discussion. The paragraphs in question alluded to disputes which have arisen during the last ten years between the College and the Fund with regard to the testamentary intentions of certain donors. Dr. G. E. HASLIP, Mr. ERNEST PAGE, K.C., the Vice-Chairman, and Sir RICHARD DOUGLAS POWELL took part in the discussion, and the last suggested the formation of a Conciliation Committee composed of a few members of the Council of Epsom College and of the Committee of the Royal Medical Benevolent Fund. The CHAIRMAN having said that a resolution to that effect, being carried by the annual general meeting, would have the greatest influence in determining the Council towards carrying out such an arrangement, the following resolution was moved, seconded, and carried unanimously:—

"That the Council be and is hereby requested and authorised to take such steps as they may think best calculated to avoid friction arising between them and the Royal Medical Benevolent Fund on any questions that may hereafter arise as to the title to funds in which either body may from time to time consider itself interested."

Mr. Horace E. Haynes was elected a Vice-President in recognition of his having collected the sum of £1000 for the Royal Medical Foundation attached to the College, when a vote of thanks to the Chairman brought the proceedings to a close.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue:—

Previously reported Missing, now reported Died of Wounds.

Capt. E. Newton, R.A.M.C., qualified at Aberdeen in April, 1915, and shortly afterwards joined up.

Died.

Capt. D. T. O'Flynn, R.A.M.C., attached R.F.A., qualified in Ireland in 1906, and held appointments at the London County Asylum, Cane Hill, and at the Isle of Man Lunatic Asylum. At the time of joining up he was assistant M.O. at the London County Asylum, Hanwell.

Wounded.

Capt. J. W. Darling, M.C., R.A.M.C., attached R.F.A.
Capt. A. Malseed, M.C., R.A.M.C., attached Liverpool Regt.
Capt. R. Craig, R.A.M.C., attd. Northumberland Fusiliers.
Major R. H. Hodges, M.C., R.A.M.C.
Major A. E. P. McConnell, M.C., R.A.M.C.
Capt. W. M. Cameron, R.A.M.C.
Capt. W. F. Shanks, R.A.M.C., attached R.G.A.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Capt. M. D. Quill, Royal Marine Artillery, died as the result of an accident whilst on leave, elder son of Surgeon-General R. H. Quill, C.B., of Cheltenham.
Lieut. K. T. Campbell, R.A.F., killed in action, only son of Lieut.-Col. S. Campbell, C.A.M.C., of Winnipeg, Canada.
Second Lieut. J. F. Northcote, West Yorkshire Regiment, reported missing in October, 1917, now believed to have been killed in action, younger son of Dr. A. B. Northcote, of Monkgate, York.
F. G. Thomas, Mercantile Marine, torpedoed at sea, fifth son of Dr. W. Thomas, of Birmingham.
Lieut. G. Wilson, R.A.F., reported missing in May, now reported killed in action, younger son of Dr. H. Wilson, J.P., of Cheadle, Cheshire.
Major C. F. Clarke, Indian Cavalry, died in hospital after long illness contracted on active service, only son of the late Dr. J. F. Clarke, of Nightingale-lane, London, S.W.

MENTIONED IN DESPATCHES.

The name of the following medical officer is mentioned in despatches:—

Surg. Andrew Harman Pearce, R.N.

FOREIGN DECORATIONS.

French.

Legion of Honour: Officer.—Surg.-Gen. J. L. Smith, C.B., M.V.O.

VENEREAL DISEASE AND THE DEFENCE OF THE REALM ACT.

During the month of June three cases of solicitation by women suffering from venereal disease in a communicable form came before the justices at Eastbourne, Brighton, and Hove. The maximum term of imprisonment (six months) was imposed at Eastbourne and Brighton and three months at Hove. The Canadian military authorities have, with the assistance of the civilian police, been taking the initiative, and an officer told the justices that the military authorities considered the Act under which the proceedings were instituted to be "the best that had ever been placed on the Statute Book." The Canadian military authorities, the officer added, were willing to prosecute in every case that came to their notice. The proceedings, it should be stated, were taken under section 40d of the Minutes of Emergency Legislation under D.O.R.A., which provides that—

"No woman who is suffering from venereal disease in a communicable form shall have sexual intercourse with any member of H.M. Forces or solicit or invite any member of H.M. Forces to have sexual intercourse with her."

The section provides also, *inter alia*, that—

"A woman charged with an offence under this regulation shall, if she so requires, be remanded for a period, not less than a week, for the purpose of such medical examination as may be requisite for ascertaining whether she is suffering from such a disease."

Syphilis, gonorrhœa, and soft chancre are cited in the section.

MEDICAL TREATMENT OF DISCHARGED DISABLED SAILORS AND SOLDIERS IN IRELAND.

FOR some weeks past the Irish Insurance Commission has had under discussion with representatives of the Irish Medical Committee a scheme for providing medical treatment for discharged disabled sailors, soldiers, and marines, and it is understood that the scheme proposed by the Commissioners, which has received general approval on behalf of the profession, is now under the consideration of the Treasury. The scheme presented greater difficulties in Ireland than in Great Britain owing to the exclusion of medical benefits from the Insurance Act in its application to Ireland. As there were no panels some other system of attendance had to be arranged, and the scheme as proposed follows closely on the lines of the scheme for certification of insured persons which has been working smoothly since the beginning of 1916. The total sums available for payment will be put into a common pool for the whole country, and medical practitioners will be paid quarterly in proportion to the work done by each. Each service rendered will have a definite "token value"—e.g., a consultation at medical practitioner's house, 1; at patient's residence, 2; with journey of defined distance, 3; operation, 4. The total sums available will accrue from a capitation rate for every discharged disabled sailor, soldier, or marine in Ireland, of 12*s.* 6*d.* for those resident in urban areas and 15*s.* for those in rural. As practitioners who join in the scheme will also receive the certification capitation grant, varying from 1*s.* 3*d.* to 2*s.* 6*d.* in different areas, the remuneration appears not to be unfair.

OBITUARY OF THE WAR.

FREDERICK ARTHUR JOHN ROBERTSON BROOKE, M.R.C.S. ENG.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain F. A. J. R. Brooke, who was killed in action in France on May 27th, was elder son of the late Thomas George Brooke, surgeon, of Langport, Somerset. Educated at Epsom College and the London Hospital, he took the qualifications of the Conjoint Board in 1894. In July, 1915, he accepted a commission in the R.A.M.C., and after taking charge of wards at Sidmouth Barracks he was appointed to the H.S. *Britannic*, and made many voyages with wounded in that vessel. Later he was at Thornhill Camp, Winchester, at a convalescent camp in France, and finally with a field ambulance.

From his student days Captain Brooke was at heart a soldier. He entered the R.A.M.C. with enthusiasm, and would have been glad to accompany his men over the parapet. His friends speak of him as an exceptionally brave man and a gifted letter-writer. He married in 1895 Constance Blanche, daughter of the late Rev. Francis Wellington Moore, of Duffield, and leaves a widow and six children. His son Cecil was killed in action at Arras on April 24th, 1917.

WILLIAM FRASER HALE, M.D. BALTIMORE,

CAPTAIN, CANADIAN ARMY MEDICAL CORPS.

Captain W. F. Hale, who died as the result of accidental injuries on June 8th, the 42nd anniversary of his birthday, was son of the Rev. Joseph Hale, of Louisburgh, Nova Scotia. He was born at Springhill, Nova Scotia, and graduated in medicine at Baltimore, Maryland (U.S.A.), in 1902. In January, 1917, he joined the C.A.M.C., went to France, and later served with a general hospital.

FRANCIS GEOFFREY THATCHER, M.B., CH.B. EDIN.,

MILITARY CROSS,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain F. G. Thatcher, who died of wounds on June 1st at the age of 27 years, was youngest son of Charles H. Thatcher, F.R.C.S., of Edinburgh. He was educated at the Edinburgh Academy and University, graduating M.B., Ch.B. in 1913. He passed into the Royal Army Medical Corps in July, 1914, and on the outbreak of war was sent almost immediately to France, attached to the Queen's Royal West Surrey Regiment. Wounded at the first battle of Ypres, he was on hospital duty in this country for a few months before being given command of a hospital ship. Being again sent to France, from May, 1917, he acted as D.A.D.M.S. to a division, and while so engaged was fatally wounded by a bomb, only surviving his injuries two days. Captain Thatcher was a keen sportsman, a member of the Edinburgh University O.T.C., and one of the team who won the Territorial Marathon race in 1910. He acted as first whip to the Edinburgh Beagle Hunt for several seasons. His cheerful disposition made him a pleasant companion and accentuates the loss felt by his colleagues and brother officers.

Captain Thatcher married, in 1915, Gladys, daughter of Maxwell Grayson, of Harrogate.

"Audi alteram partem."

ACUTE ŒDEMA OF THE LUNGS.

To the Editor of THE LANCET.

SIR,—I have only just seen in THE LANCET of May 11th Dr. F. de Havilland Hall's letter with reference to this subject. I should like to quote a case in point which I met with two years ago.

The patient, a girl aged 12, went to bed at 11 o'clock well, but became seriously ill about 12.30. I saw her at 2 A.M., when she was cyanosed, lying on her side, coughing and hawking; the frothy, tinged mucus which one finds in the trachea P.M. was pouring out of her mouth; there were râles all over lungs, and she died in about half an hour. I had never met with a description of the disease, but, strange to say, a few days after I came across an account of it in *Le Monde Médical*.

Two days ago I attended a sister of the above, aged 6 days. She had only been ill a few hours, but was slightly cyanosed, unable to swallow, no expectoration, fine râles all over both lungs. She died the following day. There is a great amount of whooping-cough about, and possibly an elder child is commencing with it.

As to the treatment by atropine, I should have been afraid to attempt it. I attended many years ago a young man for bronchitic asthma; he was spitting some three pints of frothy mucus a day. I gave atropine to check it and succeeded; but oh! how ill I made him! I had to do my best to neutralise it a few hours after, as he was nearly suffocating. I am, Sir, yours faithfully,

A. BOWES ELLIOTT, F.R.C.S. Eng.

Abergele, June 10th, 1918.

THE MEDICAL DIRECTORY, 1919.

To the Editor of THE LANCET.

SIR,—The annual circular in connexion with the Medical Directory has been sent to every member of the medical profession. It will help the editors considerably if this circular is returned promptly. If in any instance it has failed to reach a practitioner, a duplicate will be forwarded on request. We are, Sir, yours faithfully,

THE EDITORS.

7, Great Marlborough-street, London, W. 1, July 2nd, 1918.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Midwives Bill.

THE Midwives Bill passed through Committee in the House of Lords on Tuesday, July 2nd. The alterations made concerned the delegation of powers by local authorities. As the Bill now stands county councils and county borough councils cannot delegate the powers of inspection entrusted to them.

Medical Inspection and Treatment of School Children.

Clause 18 of the Education Bill deals with the medical inspection of schools and educational institutions. An amendment proposed in the House of Commons by Sir W. WATSON CHEYNE was accepted providing that the local educational authorities in making arrangements for treatment should consider how far they could avail themselves of the services of private medical practitioners.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 26TH.

Promotion in the Royal Army Medical Corps (Territorial).

Sir F. BLAKE asked the Under Secretary for War whether any and, if so, what steps had been taken to provide for the regulated promotion of officers of the Royal Army Medical Corps, Territorial Force; and, particularly, whether he would arrange to give the charge of hospitals which were lieutenant-colonels' commands to senior majors of that force of 20 to 30 years' service when they had served abroad with distinction and were strongly recommended by their commanding officers.—Mr. MACPHERSON replied: The recommendations of the committee appointed to report upon the promotion and pay of officers of the Royal Army Medical Corps have been complied with in accordance with the decision of the Government. In this connexion I would refer my honourable friend to Command Paper 8643 which was issued in January last. Duly qualified officers recommended for the posts referred to in the second part of the question are equally considered, and those best fitted for the command are appointed.

THURSDAY, JUNE 27TH.

Provision of Artificial Limbs.

Major CHAPPLE asked the Parliamentary Secretary to the Ministry of Pensions how many limbless men had been fitted with artificial limbs; how many were still unfitted; how many of those unfitted were ready and waiting to be supplied; how many of those fitted had returned for refitting or repairs; and what was the average cost of each artificial limb supplied.—Sir A. GRIFFITH-BOSCAWEN replied: Up to the end of last month 18,307 men had been fitted or were in process of being fitted with artificial limbs, and 12,855 were still unfitted. Of the latter number 4321 were ready and waiting to be supplied. It is not possible to state how many of those fitted have returned for refitting or repairs, as in many cases the orders are given direct to limb makers by local committees or commandants of military hospitals. As the prices of artificial limbs vary so greatly with the nature of the amputation, the type of limb selected, and the attachments, appliances, and fittings necessitated by the circumstances of the case, it would be misleading to name any figure as representing the average cost of each limb supplied.

Major CHAPPLE: Will he say what is being done for those who are now unfitted in the way of supplying them with temporary artificial limbs pending the provision of permanent artificial limbs?—Sir A. GRIFFITH BOSCAWEN: We are making large additional purchases, and in the next few weeks the accommodation in this respect will be much better.

Medical Grading at Bristol.

Mr. JOYNSON-HICKS asked the Parliamentary Secretary to the Ministry of National Service what was the total number of men examined and the number of men passed Grade 1 by the National Service medical boards at Bristol for the weeks ending May 4th, 11th, 18th, and 25th, and June 1st, 8th, 15th, and 22nd last, respectively; and what number of such men were between 43 and 51 years of age.—Mr. BECK replied: It would be contrary to the public interest at the present time to give the figures asked for by my honourable friend, but I may say that excluding re-examinations the percentage of the total number of men of the old military age examined at Bristol during May and the first fortnight of June who were passed Grade 1 was 71 per cent., while the percentage of the total number of men over 43 examined who were passed Grade 1 was 18·6 per cent.

Medical Examinations and Grading.

In Committee of Supply on an Estimate for the Ministry of National Service, Sir AUCKLAND GEDDES (Minister of National Service) made a long statement concerning the work of his department, with particular reference to medical examination and grading. He elaborated many of the points which he made in his speech in the House on June 20th.

He pointed out that in allocating men to the Army two considerations fell to be taken into account. The first was the purely medical consideration as to how fit a man was; the second was how the man who possessed such fitness could best be employed by the Army, and that fell to be decided by men with experience of the conditions of this war. Under the old scheme it was attempted to carry out these two functions and to get the medical men working on the medical boards to decide not only the medical problem as to how fit a man was, but also the further problem—what class of work he was fit to do in the Army. That led, as was inevitable, to great waste, because civilian medical practitioners in large measure were being asked to decide something which required military experience, and he thought that the great difficulty which led to the breakdown of the military recruiting boards was the imposition of this double function upon them. This system was changed after the medical examination of recruits was taken over by a civil department, and the advice received from the Medical Advisory Board and a large number of civil consultants was that the furthest a medical board composed of civil medical practitioners should be expected to say was whether a man was fit for his age. That was the advice which lay behind the terms Grade 1, Grade 2, and Grade 3 when they were introduced last autumn. The system of posting the men to the various branches of the Army took account both of the man's grade and the man's age. The whole of the posting was carried out under most careful supervision. When the men went to the reception station there was a posting board, which consisted of a field officer who had experience of how men of various ages were standing, a medical officer, and also a posting officer, who had full information given to him every month as to the requirements of each of the arms of the service and the classes of men who should be posted to the various arms. The medical men (the right honourable gentleman proceeded) who were doing the medical examinations for the Ministry of National Service were not officials, but in the vast majority of cases they were civil practitioners who were giving a portion of one, two, three, or four days in the week to help in this work.

Mr. P. A HARRIS: What is the tenure of their office? Are they subject to dismissal?

Sir A. GEDDES: The medical men are provided by the profession itself through its local official organisations, the local war (executive) committees. They prepared panels which included medical men in practice in the district, who were willing or who had time to do a certain amount of work on the medical boards. The local war (executive) committee might refuse to put a man's name on the panel. That, he believed, had happened, but no Government Department had anything to do with whether a man's name was on the panel or not, or was removed from the panel or not. They were paid by sessions of two and a half hours. These medical men were not in any sense servants of the Ministry of National Service; the Ministry did not, in fact, appoint them, but gave a formal approval which had never been withheld from the names sent forward by the local professional committees. Nor did any Government Department dismiss them. If any individual on one of the panels was guilty of misconduct the tribunal which would decide would be in the first instance the local war executive committee of the medical profession, and if it thought it a case of misconduct it would remove a man's name from the panel. So in fact there was no Government control over the individual medical men who were working on these boards. It was recognised that there would in all probability—and he believed that this was absolutely borne out by experience—be a far higher standard of professional work if the Ministry left it to the profession itself to select the men who were to perform it.

General Directions to the Boards.

The general directions with regard to the working of the boards—that was to say, the professional technical medical direction, not the administrative direction about hours, pay, and so on—were issued from the Ministry of National Service after consultation with the heads of the profession. They were issued after full discussion by the medical officers in the Medical Advisory Board and there was consultation in all cases dealing with certain physical disabilities with recognised specialists in particular branches of the profession. Once these instructions were issued the whole of the medical boards were expected to conform to them. A great deal of the recent criticism of medical boards had been directed to the wrong place. The medical boards had been working very well in the overwhelming majority of cases. The criticism about the grading of the older men that had been hurled at these boards had been, in his opinion, directed to the wrong place. It ought to have been directed against the Minister. There had been a lot of criticism directed quite unfairly against the practitioners who constituted the boards. They had been accused of grading men without proper examination, and so on. That might have happened in the case of one or two boards, but it was certainly not the case with regard to the vast majority. There were no fewer than 2500 medical practitioners from civil practice who were the very salt of the profession on the general practice side working on these boards. They did the work, not because it paid them, but out of a spirit of patriotism and because they realised that at this time it was a form of national work which they could do for the country. The right honourable gentleman, with the assistance of diagrams, explained what had been done with regard to the examination of the older men, and said that less than one-third of 1 per cent. of them had been posted. A man who was dissatisfied with his grading had a right of appeal to a National Service medical board for re-examination. Afterwards an appeal tribunal might send him to the medical assessors.

Mr. MCKINNON WOOD: Suppose the medical officer at the reception station classifies the man in a higher grade than he is classified at his medical examination—what is his position then?

Sir A. GEDDES: The medical officer there cannot classify him. He cannot put a man up. He can only send a man back.

Mr. MCKINNON WOOD: He has done so. I know of cases.

Sir A. GEDDES: I would be very much obliged to my right honourable friend if he will let me have any cases, because that is strictly against the instructions. He would certainly consider the question of putting up a notice at the boards, explaining the rights of appeal which a man had. The older men were carefully differentiated in their medical history sheets from the younger men. It was not intended to use the older men primarily in the first line trenches, or even in assault work. As far as possible the War Office had pledged itself to accept the undertaking to put the men of the new age-period to secondary services in connexion with the Army.

Important Suggestion.

Sir DONALD MACLEAN (who is chairman of the House of Commons Appeal Tribunal) said that the demand was now made to the Ministry that the men of the older ages should have at least as favourable a medical examination as the men of the lower ages. What was the definition of Grade 1? In the National Service Instruction, dated Nov. 17th, 1917, it was stated: "Grade 1 is generally equivalent to Category A, i.e., general service in the old classification." The definition went on: "It includes those who attain the normal standard of health and strength, and are capable of enduring the amount of physical exertion suitable to their age. They must be free from any organic disease or deformity." That was followed by M.N.S.R. 24 at a later date. He did not quite know that date.

Sir H. NIELD: In May.

Sir D MACLEAN: Then that was after the passing of the last Military Service Act. I will read it. "Grade 1. This grade will comprise those who attain the normal standard of health and strength and are capable of enduring physical exertion suitable to their age. The men must not suffer from any organic disease, with certain exceptions specified hereafter, and must have no grave physical disability or deformity. Minor defects, such as of the teeth and of eyesight, which can be removed or compensated for by artificial means, will not be regarded as disqualifications. Men who fulfil the conditions of Grade 1 will also be fit for general service in the Army." Again, there was "general service." In the first circular quoted by him they were the governing words, at the start of the definition. Here they were at the end, but still they were the dominating words of the whole definition. Now he came to another document, which was of April 29th, 1918. "Amendment of M.N.S.R. 24, Grade 1. The older men will be placed in Grade 1 if they possess the full normal physical fitness to be expected of their age. Such men must not have any serious physical defect and must not suffer from progressive organic disease. They must be able to endure physical exertion involving a considerable degree of strain, and to undergo gradual physical training in order to fit them for military duty. *Note.*—The physical training for the older men in this grade will be carried out under special medical supervision." There was not one word in the circular of April 29th of men of this class being fit for general service. There could be no conclusion other than this, that there was a change in the physical standard by which men were to be examined after the Act was passed as compared with when the Bill was in the hands of the House. Not only was that change made in the circular, but it was made in the instructions to the medical officers. When men came up classed Grade 1 before the tribunals they did not get the same consideration. Grade 1 men were wanted, and the result was that at the tribunals the men of the older age were getting far less consideration as compared with men of the lower age under the conditions. In his tribunal he had taken a drastic step in dealing with the older men of Grade 1. All he could do was to say, "Very well; it is called Grade 1. The only way we can work it is to call it Grade 2." He suggested that five or six Members of the House who had great experience of tribunal work, with the honourable Member for the University of Edinburgh (Sir W. Watson Cheyne) and the honourable Member for Derby (Sir William Collins), who were great experts in the medical profession, should meet and consider these matters. He was quite certain that they could thus settle the whole thing, always providing that they got rid of this physical standard of fixing a man's grade according to his age and not according to his physical fitness for the Army.

Sir WILLIAM COLLINS remarked that there was a good deal of confusion of thought in the proposition that a man who was fit for his age was therefore fit for some service in the Army. The medical profession required no justification. It had done its service nobly in the war; but it could not do impossible tasks. He did think that the method of making examinations, whether according to category or by the grade system, was setting an impossible task to the medical profession.

Conference with Chairmen of Tribunals Accepted.

Mr. LLOYD GEORGE said that he understood his right honourable friend (Sir Donald Maclean) had thrown out the suggestion that Members of the House who were chairmen of tribunals should meet the Minister of National Service and try to clear the matter up. It was an admirable suggestion and was far and away the best means of clearing up misunderstanding. He believed that there were seven honourable Members who were chairmen of tribunals and had direct and special experience of the administration of the Act. The Minister for National Service thought it desirable that these gentlemen should come together and interchange views, so that his right honourable friend should get the benefit of the special experience of those who were administering these Acts and should clear the matter up. He had not the faintest doubt that if they did meet all these difficulties would be swept on one side and the public would be considerably reassured in regard to the subject. He was very glad to be able to say that they had arranged to meet. The sooner they met the better, because it was interfering with the administration of the Acts and the need for men was very great. For that reason he hoped the meeting would be arranged at the earliest possible moment, and that they would be able to clear up these difficulties. He knew that the men from 41 to 51 were only too anxious to do their best for their country, but they wanted to be treated fairly. It was the intention of the Minister of National Service that they should be fairly treated. In his (Mr. Lloyd George's) judgment, and in the judgment of his right honourable friend, they were being treated fairly, but there was a misunderstanding about it. Therefore let the matter be cleared up.

The Medical Profession and Military Service.

In the course of the subsequent debate Sir W. WATSON CHEYNE dealt with some of the aspects of the relation of the medical profession to the recent Military Service Act. He said that he had received a number of communications from the older members of the profession asking whether it was necessary that they should leave their practices where they were doing a large amount of work to go elsewhere to meet the needs of the Army. He asked whether the Minister of National Service had assured himself that there was not a waste of medical man power in the Army in France. A committee which had investigated this matter had reported last December, and the non-publication of the report was giving rise to a great deal of trouble among medical men. He would ask whether the right honourable gentleman had satisfied himself by a consideration of that report that it was necessary to call on medical men to leave their practices. If he had not done so, would he do so and get it published, so that medical men might see what it contained. Medical men, especially those over 50, were filled with anxiety lest they should be asked to leave their practices, which would mean ruin to them, and to go and take up practice, say, in a mining district. At that age they were not, in many cases, physically strong enough to carry on a practice of that kind. On the other hand, they professed their readiness to take a commission in the Army and do work in base hospitals and in other ways, so as to allow the younger men to be sent abroad. One suggestion had been made in some quarters was that temporary employment in the R.A.M.C. should be offered for periods in the summer months when the work abroad was heaviest. A return to practice might be allowed in winter, when the demand at the front was less. A certain number of medical men objected to be sent to do panel work. He thought that the older men might be given part-time work in their own neighbourhood as far as possible. He could not help thinking that the raising of the age of service to 55 had been a little rash, and he hoped that means would be taken to mitigate the hardships as far as possible.

The vote had not been agreed to when the debate terminated.

TUESDAY, JULY 2ND.

Whole-time Women Doctors in the Army.

Sir ROBERT NEWMAN asked the Financial Secretary to the War Office whether he was aware that women serving as whole-time doctors in the Army and doing precisely the same work as their male colleagues received neither military rank nor status, thereby being deprived of equal pay, ration, and travelling allowances, as well as a gratuity; that they had their letters censored and suffered under many other disabilities owing to their not holding commissioned rank; and whether, under these circumstances, steps would be taken to grant women temporary commissioned rank, thus removing these grievances, and at the same time showing a just appreciation of the services rendered by women doctors in connexion with the war.—Mr. FORSTER replied: My honourable friend is misinformed. Women serving as whole-time doctors in the Army for service at home and abroad receive the same pay, ration, and travelling allowances and gratuity as temporary commissioned officers of the R.A.M.C. Those serving for home duty only on temporary engagements are treated in the same way as civilian medical men similarly employed. All officers have their letters censored. It is not proposed to grant commissions to women doctors.

A Ministry of Health.

Major ASTOR asked the Minister of Reconstruction whether he could state when he would be in a position to introduce a Bill setting up a Ministry of Health.—Dr. ADDISON answered: The Bill on this subject is under the consideration of the Government and I am not able to make any statement as to its introduction.

Glycerine for Medicinal Purposes.

Mr. MOLTENO asked the Parliamentary Secretary to the Ministry of Munitions whether it would now be possible to arrange for the release of a suitable quantity of glycerine for the preparation of medicines of which it was an ingredient and meet a want which was pressing.—Mr. KELLAWAY replied: Glycerine is released for medicinal purposes where it is indispensable, competent medical advice being taken in doubtful cases.

ROYAL INSTITUTION.—A general meeting of the members was held on July 1st, Sir James Crichton-Browne in the chair. The Duke of Northumberland was elected President and Sir Thomas Wrightson a visitor, while the treasurer announced that the managers had appointed Sir James Dewar Fullerian Professor of Chemistry.

METROPOLITAN HOSPITAL SUNDAY FUND.—The following are among the amounts received at the Mansion House up to July 2nd, the total sum to date being £46,000.

American Red Cross Commission, £5000; St. Mark's, North Audley-street, £2453; St. James's, Piccadilly, £356; Watts, Watts, and Co., Ltd., £315; Mr. John Latta, £282 10s.; Paddington Parish Church, £239; Brompton Parish Church, £238; Lieut.-Col. More Nisbett, £200; Mr. Alexander Miller, £200; Chapel Royal, St. James's £156; St. Paul's, Finchley, £145; All Saints, Eaulsmore-gardens, £131; Westminster Chapel, £120; Emmanuel, Wimbledon, £118; C. Goodall and Son, Ltd., £105; Cory Bros. and Co., Ltd., £105; United National Collieries, Ltd., £105; W. Gardiner and Co., Ltd., £105; London and Brazilian Bank, Ltd., £105; Wilson, Sons, and Co., £105; Dorman Long and Co., £100; Mrs. E. H. Stevenson, £100; St. Alphage, London Wall, and St. Mary, Aldermanbury, £100; Hong-Kong War Charities Committee, £100; Sloper Bros., £100; Mr. W. D. Graham-Menzies, £100; Messrs. Erlangers, £100; Vivian, Younger, and Bond, £100; Mr. J. A. Roberts, £100.

THE LANCET, VOL. I., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of June 29th is in preparation. Owing to the increasing shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a *post-card* (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

Medical News.

UNIVERSITY OF OXFORD.—At examinations held recently the following candidates were successful:—

SECOND M.B. EXAMINATION.

Materia Medica and Pharmacology.—J. Harris, Jesus; B. G. Von Brandis Mellé, Brasenose; and K. F. D. Waters, Keble.

Pathology.—B. G. Von Brandis Mellé, Brasenose.

Forensic Medicine and Public Health.—E. H. Cluver, Magdalen; J. C. Dixey, Brasenose; S. C. Dyke, Exeter; C. F. Krige, Hertford; J. E. B. Morton, Queen's; T. Patterson, non-collegiate; W. V. Robinson, New; A. E. Thomas, University; and K. F. D. Waters, Keble.

Medicine, Surgery, and Midwifery.—E. H. Cluver, Magdalen; S. C. Dyke, Exeter; T. Patterson, non-collegiate; W. V. Robinson, New; J. J. Savage, Brasenose; K. F. D. Waters, Keble; and E. A. Woods, Magdalen.

UNIVERSITY OF CAMBRIDGE.—At examinations for medical and surgical degrees held in Lent and Easter terms the following candidates were successful:—

SECOND EXAMINATION.

Part I., Human Anatomy and Physiology (March).—J. G. D. Currie, Peterhouse; J. H. Doggart, King's; A. C. V. Gosset and S. Orchard, Caius; and L. R. W. Price, Sidney Sussex. Women: J. R. Batten, Newnham; and D. A. D. Cropper, Girton.

Part II., Pharmacology and General Pathology (April).—C. C. Beney, Jesus; N. D. Dunscombe, Downing; H. Franklyn, Christ's; D. G. Garnett, Pembroke; N. B. de M. Greenstreet, St. John's; C. Griffith Jones, Caius; W. E. Heath, Queens'; C. A. Horder, Emmanuel; H. A. A. Pargeter, Sidney Sussex; R. Y. Paton, Trinity; C. V. Patrick, Caius; M. L. Sawhney, Downing; C. Suffern, Emmanuel; and M. L. Young, Caius.

Part I., Human Anatomy and Physiology (June).—W. D. Doherty and C. I. C. Gill, King's; S. H. G. Humfrey, Caius; P. Lazarus-Barlow, Downing; J. R. Lund, Catherine; L. B. Maxwell, Caius; O. G. Misquith, Christ's; C. Sturton, St. John's; K. H. Tallerman and G. I. F. Tweedie, Caius; C. E. Whitting, Christ's; and H. L. Willey, Caius.

THIRD EXAMINATION.

Part I., Surgery and Midwifery (June).—G. T. Calthrop, Emmanuel; F. N. V. Dyer, Clare; G. A. Fisher, Jesus; F. Gray, Caius; N. B. de M. Greenstreet, St. John's; R. J. Hearn, Jesus; L. G. Higgins, Clare; C. McC. Jones, Downing; S. D. Kilner, Emmanuel; J. H. E. Moore and R. A. Olphert, Caius; N. Rumboll, Emmanuel; A. H. J. Smart, Caius; and J. Whittingdale, Downing.

Part II., Medicine, Pathology, and Pharmacology (June).—A. B. Appleton, Downing; I. de B. Daly, Caius; E. A. Green, Emmanuel; L. G. Higgins, Clare; B. B. Jareja, Trinity; J. D. Jones, H. Selwyn; S. D. Kilner, Emmanuel; J. H. E. Moore and H. Morrison, Caius; A. H. Pearce, Clare; C. H. Vernon, St. John's; and F. G. Wood, Jesus.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates were successful in the subjects indicated:—

Surgery.—G. H. Fitzgerald (Sect. II.), Guy's Hosp.; and H. M. Waller (Sect. II.), St. Bart.'s Hosp.

Medicine.—W. E. P. Briggs (Sects. I. and II.), Manchester; N. Cheua (Sect. II.), Middlesex Hosp.; D. A. Dyer (Sect. II.), St. George's Hosp.; G. H. Fitzgerald (Sect. II.), Guy's Hosp.; and F. W. Kemp (Sect. I.), Charing Cross Hosp.

Forensic Medicine.—H. Carter, London Hosp.; and F. W. Kemp, Charing Cross Hosp.

Midwifery.—W. E. P. Briggs, Manchester; J. F. E. Burns, Bristol; J. Gorsky, Westminster Hosp.; F. W. Kemp, Charing Cross Hosp.; and E. H. Musgrove, Cardiff and Guy's Hosp.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: W. E. P. Briggs, D. A. Dyer, G. H. Fitzgerald, and H. M. Waller.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful in the subjects indicated:—

FINAL M.B. AND CH.B. EXAMINATION.

T. H. Almond, Sybil Bailey, Mary G. Cardwell, Thomas Colley, S. E. Critchley, F. L. Heap, John Mills, Kathleen O'Donnell, Norah H. Schuster, L. J. Schwartz, V. T. Smith, and F. L. Whincup.

Obstetrics.—James O'Grady and Bryan Walley.

Forensic Medicine and Toxicology.—Nooman Abdoh, Mary E. Boullen, Elizabeth C. Davies, Kathleen Doyle, Georgiana M. Duthie, Olive M. Gimson, F. G. Hamnett, Archibald Harris (distinction), Simon Kelly, J. G. Nolan, James O'Grady, Olga G. M. Payne, F. L. Pickett, Ellis Pigott, William Reikan, A. El. H. Sadek, Annie G. Thompson, Dorris M. R. Tompkin, Brian Walley, Ethel D. Willis, and Ruth A. Wilson.

THIRD M.B. AND CH.B. EXAMINATION.

Pharmacology, Therapeutics, and Hygiene.—Samuel Adler, May Ashburner, F. A. van Collier, Phyllis M. Congdon, J. W. Crawshaw, K. V. Deakin, A. M. El-Aguizy, F. R. Ferguson, Evelyn A. Garnett, Joshua Harris, G. E. Hayward, Sylvia K. Hickson, J. B. Higgins, F. S. Horrocks, Irma M. C. Jéhansart, F. C. Jones, Mary S. Jones, H. A. Lomax, W. E. Mason (distinction), Doris B. Norman, E. R. Ormerod, Emily M. Peach, H. D. Preston, Harry Rosenthal, Gerald Sheehan, Annie E. Somerford, Geoffrey Talbot, Doris A. Taylor, G. L. Taylor, H. W. Taylor, Mary I. Turner, and Raymond Williamson.

Hygiene.—Martha F. Barritt, Florence M. L. Graham, A. S. Leigh, and Bertha Renshaw.

SECOND M.B. AND CH.B. EXAMINATION.

Simon Almond, Ernest Jones, and J. S. Robinson.

DIPLOMA IN DENTISTRY (FINAL EXAMINATION).

Norman Flitcroft, and E. L. Morgan.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on June 25th the following degrees were conferred:—

Doctor of Medicine for Practitioners of 15 Years' Standing.—Kenlyn Cobham Edwards and Percy Arthur Storey.

Bachelor of Medicine and Bachelor of Surgery.—Dorothy Edith Butcher, Cyril Charles Herbert Cuff, Wallace Alexander Freedman, Mary Kathleen Henegan, William Andrew Hewitson, William Arthur Jaques, Bertram Sergeant, and William Edward Mandall Wardill.

Bachelor of Surgery.—Stephanie Patricia Laline Hunte Taylour Daniel.

Bachelor of Hygiene and Diploma in Public Health.—Harold Mason Leete.

At the Third Examination for the degree of Bachelor of Medicine the following candidates were successful:—

Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology.—Tom Hugh Ronald Anderson, Paige Canney Arnold, Neil Robertson Beattie, Robson Christie Brown (second-class honours), Samuel Whately Davidson, Mark Julius Erdberg, Alfred Stoddart Graham, Mary Louise Griffiths, Kate Gray, Dorothy Holmes, George Hurrell, Edith Catherine Morris Jones, Malik Abdur Rahman Mansoor, Thomas Norman Vickers Potts, May Raw, Joseph Silverston, Henry Rochester Smith, James Stonehouse, Athelstan Woodman, Kathleen Mary Weldon Watts, and Arthur Guy Weston (second-class honours).

UNIVERSITY OF GLASGOW.—The following degrees were conferred on June 26th:—

DOCTOR OF MEDICINE (M.D.).

Thomas Symington Macaulay (commendation) and Thomas Baxter.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following candidates have passed the Final Dental Examination and have been granted the diploma of L.D.S. R.C.S. Edin.:—

John Kohler Steel and Daniel van der Merwe du Toit.

NATIONAL UNIVERSITY OF IRELAND.—The degree of M.D. (honoris causâ) has been conferred upon Colonel R. J. Blackham, C.M.G., C.I.E., D.S.O.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—A garden party in aid of the Guild will take place in the Royal Botanic Gardens, Inner Circle, Regent's Park, London, on Tuesday, July 16th, from 2.30 to 7 P.M. There will be music provided by bands, dancing in a ball-room marquee, concerts at 3 and 3.45 by distinguished artists, and gift sales at 3.30. Practically the entire fête will be covered in ("weather absolutely guaranteed") and tea and refreshments will be provided. Admission 2*s.* 6*d.*; concert, 2*s.* 6*d.*; tea, 2*s.*; dancing, 2*s.* 6*d.* The chairman of the Guild is Lady Tweedy, 100, Harley-street, London, W. 1, from whom and 25 other ladies named in the handbill tickets can be obtained, as also from Keith, Prowse, and Co., Alfred Hays, Ashton, and Mitchell, and the District Messenger Co. The honorary organiser is the Earl of Wilton, Cassiobury, Watford.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on June 19th, with Sir Francis H. Champneys in the chair. Certain midwives were struck off the roll, the following charges, amongst others, having been brought forward:—

Being in attendance at a confinement, a midwife was guilty of negligence in the following respects: The placenta and membranes not having been completely expelled within two hours after the birth of the child, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (3); the patient being in the condition aforesaid, the midwife neglected to hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might immediately be forwarded to a medical practitioner or to an

approved institution, as required by Rule E. 20; the midwife not being scrupulously clean in every way, including her person, clothing, and appliances, as required by Rule E. 2, and not keeping her register of cases, as required by Rule E. 24. Medical aid having been sought for the patient, the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (a); she neglected to provide for the comfort and cleanliness of the patient during the ten days following, as required by Rule E. 12; she neglected to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14; and she neglected before leaving the patient's house to remove the soiled linen from the patient's neighbourhood and from the living-in room, as required by Rule E. 11. A child suffering from inflammation of, and discharge from, the eyes, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5). A midwife being drunk on duty while in attendance at a confinement, thereby being guilty of misconduct within the meaning of Section (3) (V.) of the Midwives Act, 1902.

At the meeting on June 20th a communication was considered from the Acting Registrar of the General Medical Council with reference to the action of a registered medical practitioner who had given a certificate to an uncertified woman certifying that she was "quite capable of undertaking the duties of an ordinary midwife." The Board decided that the chairman be asked to communicate with the President of the General Medical Council and to express the views of the Board on the doctor's letters.—A letter was considered from the Acting Medical Inspector of Midwives for the city of Bristol asking the Board to support a suggestion which he had made to the Food Controller proposing that midwives in active practice should be entitled to an extra meat ration. The Board decided that, while approving the suggestion, the Board does not see its way to initiate action in the matter.—A letter was considered from the Secretary of the Brighton Hospital for Women asking the opinion of the Board as to whether, having regard to the Board's resolution 12 (b) of May 16th, 1918 (Minutes, vol. v., p. 191), a pupil may be employed after delivery to act, under the conditions mentioned, as an assistant for a qualified midwife for visiting purposes only, although the midwife is primarily responsible. The Board directed that on the facts as stated a pupil may be employed as an assistant to a certified midwife provided that it is understood that the employment of an assistant in no degree relieves the midwife in charge of the case from all the responsibility entailed on her by the rules.

MEDICAL MAGISTRATE.—Dr. H. J. Thornton, of Acton, has been appointed a justice of the peace for the county of Middlesex.

AT their recent meeting the Senate of Glasgow University awarded the Bellahouston gold medal to Mr. R. T. Leiper, M.D., D.Sc., of the London School of Tropical Medicine, for his contributions to medical helminthology.

URBAN VITAL STATISTICS.

(Week ended June 29th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 13·2, against 11·4 and 11·7 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was also 13·2, and was 1·2 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 3·9 in Oxford, 4·2 in Edmonton, and 4·5 in Wolverhampton to 23·7 in Huddersfield, 23·8 in Merthyr Tydfil, and 30·2 in Stockton-on-Tees. The principal epidemic diseases caused 294 deaths, which corresponded to an annual rate of 0·9 per 1000, and included 109 from measles, 107 from whooping-cough, 30 from diphtheria, 27 from infantile diarrhœa, 12 from scarlet fever, and 9 from enteric fever. Measles caused a death-rate of 1·5 in Hull, 2·2 in Wakefield, 2·5 in West Hartlepool, and 4·4 in Barnsley; and whooping-cough of 1·8 in Enfield and in Walsall, and 3·5 in Merthyr Tydfil. The 857 cases of scarlet fever and 1189 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 30 above and 4 below the respective numbers remaining at the end of the previous week. The 1017 deaths from all causes in London included 67 from influenza, against 5 and 10 in the two preceding weeks. Of the total deaths in the 96 towns 130 resulted from violence. The causes of 44 deaths were uncertified, of which 12 were registered in Birmingham, 4 each in Liverpool and Gateshead, and 3 each in London and Sunderland.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 11·5, against 10·9 and 11·8 per 1000 in the two preceding weeks. The 250 deaths in Glasgow corresponded to an annual rate of 11·7 per 1000, and included 16 from whooping-cough, 11 from measles, 4 from infantile diarrhœa, 3 from diphtheria, and 1 each from scarlet fever and typhus. The 78 deaths in Edinburgh were equal to a rate of 12·2 per 1000, and included a fatal case each of whooping-cough and diphtheria.

Irish Towns.—The 120 deaths in Dublin corresponded to an annual rate of 15·7, or 1·2 per 1000 below that recorded in the previous week, and included 2 each from measles and infantile diarrhœa and 1 from whooping-cough. The 341 deaths in Belfast were equal to a rate of 45·2 per 1000, and included 10 from whooping-cough and 2 from infantile diarrhœa.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

L. Gibson to be temporary Surgeon.

ARMY MEDICAL SERVICE.

Col. (temp. Major-Gen.) G. B. Stanistreet, C.B., C.M.G., temporary Deputy Director-General, to be Deputy Director-General.

Col. (Hon. Surg. Gen.) Sir J. Maher relinquishes the temporary rank of Major-General on ceasing to be specially employed.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. G. J. Houghton to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

Capt. R. B. Phillipps relinquishes the acting rank of Lieutenant-Colonel and reverts to the acting rank of Major (with pay and allowances of his substantive rank).

Temp. Major E. L. Gowlland relinquishes the temporary rank of Lieutenant-Colonel on re-posting.

Capt. J. D. Kidd to be acting Lieutenant-Colonel whilst employed as Assistant Director of Medical Services.

Capt. J. Rowe relinquishes the acting rank of Major on re-posting.

Capt. E. D. Caddell relinquishes the acting rank of Lieutenant-Colonel and reverts to the acting rank of Major (with pay and allowances of his substantive rank).

Temp. Capt. A. J. Clayton to be acting Major whilst specially employed.

Temp. Capt. J. L. Jackson to be acting Major.

Lieutenants (temporary Captains) to be Captains: G. B. Hadden, H. C. Gooding.

Temporary Lieutenants to be temporary Captains: R. Calleya, J. S. Young, T. Gardner, A. H. Hall, J. T. Daly, D. R. Acheson, G. McNeill, P. Murphy, E. C. Tamplin, E. McK. Reid, J. L. Rankine, G. L. N. Miles, E. H. Noney, I. J. Roche, R. H. Dix, W. O. McKane, G. Wacher, J. E. MacFarlane, W. H. Pallett, W. Fleming, E. Lewis, R. W. Eddie, P. de S. Smith, A. H. Southam, J. W. Johnstone, J. B. O'Reilly, R. W. Reid, T. C. Innes, E. G. van B. Bergh, H. G. Barrie, W. Deane, L. C. W. Cane, H. R. Elliott, S. M. MacKenzie, G. McQ. Brunton, S. S. Brook, D. M. Humby, J. H. Porter, A. Roemmele, R. W. Brown, J. Wells, R. F. Lunn, H. D. Matthews, W. Kingdon, J. W. Miller, M. Stewart, H. A. Edwards, F. H. Kitson, F. R. L. Atkins, M. Macleod, E. F. Wills, S. H. Robinson, E. Thorp, T. D. Webster, J. C. Marshall, E. D. Struthers, F. M. Auld, C. E. Waldren, N. R. Ussher, F. W. W. Smith, W. B. H. Dundee, P. Hall-Smith, F. Thompson, R. H. Robinson, L. M. Markham, C. E. Lakin.

J. C. Turnbull, late temporary Captain, is granted the honorary rank of Captain.

To be temporary Lieutenants: E. R. Wheeler, I. Hodgkinson, C. H. Broomhead, J. B. McGranahan, E. F. Crabtree, C. G. Seligman, R. Rae, D. E. Carter to be temporary Honorary Lieutenant.

Officers relinquishing their commissions: Temp. Majors H. S. Raper, V. J. Blake; Temp. Capts. T. Pretsell, A. Emery, H. R. Sedgwick, J. C. Houston, W. R. White-Cooper, C. R. R. Huxtable, J. A. Vlasto, R. M. Forde, I. Campbell, F. W. Harrowell, R. C. Fuller, R. W. Ryan, W. Rogerson, H. F. Nolan, T. Gilchrist, A. J. Trinca, G. B. Simpson, G. D. Kerr, M. A. McKeever, E. H. Price, G. Holroyd, J. A. Tobin, E. A. Aylward, J. M. Morrissey, H. F. Vandermin, R. H. King, J. A. Giles, B. Beamish, W. Oliver, F. W. Davidson, H. C. A. Haynes, L. M. Dawson, R. W. Hogg, P. A. Doyle, J. F. Field, G. S. A. Bishop, K. Black, J. T. Courtice (and is granted the honorary rank of Captain), J. Loudon (and is granted the honorary rank of Captain), R. L. S. Nuthall; Temp. Capts. M. A. MacKinnon, H. P. Hamilton, R. L. Shields, H. R. Hurter (on account of ill health, and is granted the honorary rank of Captain); Temp. Lieuts. J. M. H. Caldwell, H. L. Blackley, J. H. Hall, M. B. Taylor, D. L. Davies, H. G. Bywater, F. J. Thornton, A. G. Gamble, H. W. Jeans, J. P. Moran, D. Ross, W. M. Brown, H. W. P. Young, W. C. Mayo, G. E. Downs, A. Fraser, W. T. Lydall, T. W. Lonsdale, W. A. Sharpin, R. F. Ballantyne, J. J. S. Scrase, F. Baillie, J. McKelvey, G. C. McL. Barber, F. W. Stewart, J. S. Higgs, R. W. H. Hillis, S. C. Jellicoe, H. L. Wilson, C. H. Wilson, F. R. Carroll, F. M. Matheson, S. Spencer; Temp. Hon. Lieut. C. E. Allison.

SPECIAL RESERVE OF OFFICERS.

Major W. A. Dingle is retired under the provisions of Para. 116, T.F. Regs., and is granted permission to retain his rank and to wear the prescribed uniform.

Major R. A. Bickersteth is restored to the establishment.

Capt. F. G. Stuart relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Captain.

Capt. W. H. L. McCarthy relinquishes the acting rank of Major on re-posting.

Lieutenants to be Captains: D. C. Beaumont, J. E. Carpenter, E. B. Andreae, K. Masson, J. A. Martin, N. M. Lewis, A. T. Woolward, M. F. Murphy, J. Wilson.

Granted temporary commissions as Captains: A. L. George, F. N. B. Smartt.

D. C. Rennie, from Birmingham University Contingent O.T.C., to be Lieutenant.

Granted temporary commissions as Lieutenants: H. G. James, H. L. Smallbone, S. G. Smith.

Lieut. G. O. Roper, from Flying Branch (K.B.), to be Lieutenant.

TERRITORIAL FORCE.

Major F. E. Fremantle to be Lieutenant-Colonel.

Major (temp. Lieut.-Col.) C. A. Stidston relinquishes his temporary rank on ceasing to command a Field Ambulance.

Capts. T. R. W. Armour, F. H. Robbins, and G. N. Anderson to be acting Majors whilst specially employed.

Major A. Cooke is seconded for service overseas.

Capts. J. Hobbs and A. B. Murray to be Majors.

Capt. (Brevet Major) H. F. Horne is seconded for service with R.A.F.

Capt. A. S. Parkinson relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Captain.

Capt. (acting Lieut.-Col.) A. T. Mulhall relinquishes his acting rank on alteration in posting.

Capt. N. C. Rutherford, from T.F. Res., to be Captain.
J. T. A. Walker to be Lieutenant.

ROYAL AIR FORCE.
Medical Branch.

Lieut. (temp. Capt) C. H. Biddulph-Pinchard to be temporary Major whilst employed as Administrative Major.
Lieut. F. R. McCambley to be Captain.

Walsall Education Committee.—L.T. Sch. Med. Insp. £400.
West Riding of Yorkshire, Maternity & Child Welfare.—Med. Prac. £400.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at East Nottingham.

Births, Marriages, and Deaths

BIRTHS.

BATCHELOR.—On June 26th, at Fons George House, Taunton, the wife of the late Major H. W. Batchelor, R.A.M.C., of a daughter.
HEWITT.—On June 20th, at Bernard-gardens, Wimbledon, the wife of Fleet-Surgeon D. Walker Hewitt, C.M.G., F.R.C.S., R.N., of a daughter.

MARRIAGES.

GODDARD—EDWARDS.—On June 25th, at the Presbyterian Church, Mold., Captain C. E. A. Goddard, M.B., R.A.M.C., to Enid, second daughter of the late Dr. David Edwards, J.P., and Mrs. Edwards, Tanybryn, Mold, N. Wales.
MUIR—CARTWRIGHT.—On June 26th, at the Parish Church, Cannington, Captain W. A. Muir, R.A.M.C., to Ann Liddon, daughter of Edward C. Cartwright, Belvedere, Cannington.
WADE—ALEXANDER.—On June 22nd, at St. Andrew's Church, Rugby, Captain (acting Lieutenant-Colonel) E. W. Wade, D.S.O., R.A.M.C., to Winifred, daughter of Mr. and Mrs. Alexander, of Dublin.
WALMSLEY—TURNBULL.—On June 27th, at St. Martin's Church, Bedford, by the Rev. F. H. A. Williams, Norman W. Walmsley, M.B., D.P.H., late Captain, R.A.M.C., to Mary E. Turnbull, eldest daughter of Mrs. Turnbull, Clapham-road, Bedford.

DEATHS.

MEADOWS.—On May 8th, Frederick Evelyn Woolner Meadows, M.R.C.S., L.R.C.P. Lond. (Middlesex Hospital), of Otley, Ipswich, aged 39 years.
SERRA.—On June 30th, at his residence, Rushmere, Newton-by-Chester, Claude L. Serra, M.D., late of Eccles, Manchester.
SHARP.—On June 10th, in India, of cholera, Maria Sharp, L.S.A., M.D. Brux., aged 55.
WILLIS.—On June 26th, W. Morley Willis, F.R.C.S., 7, Regent-street, Nottingham.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.
MEETING OF SECTION.
Monday, July 8th.

ODONTOLOGY (Hon. Secretaries—F. N. Doubleday, J. Howard Mummery): at 7.30 P.M.
Casual Communication:
Mr. Ernest Sturridge: A Case of Rheumatoid Arthritis treated by Ionization of Periodontal Membrane.
Paper:
Mr. F. N. Doubleday: Local Anæsthesia in Dental Operations.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
Clinics each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.
(Details of Post-Graduate Course were given in issue of June 29th.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Out-patients each day at 2.30 P.M.

COLLEGE OF AMBULANCE, 3, Vere-street, Cavendish-square, W.
Course of Special Lectures and Demonstrations on Ambulance Work and First Aid (illustrated as far as may be possible and followed by a Discussion).
THURSDAY, July 11th.—4.30 P.M., Lecture IX.:—Dr. J. M. H. Macleod: First Aid in the Management of Burns and Scalds.

ROYAL SANITARY INSTITUTE, at the Town Hall, Swindon.
SATURDAY, July 13th.—11 A.M., Discussions:—Infant Welfare Work and its Difficulties (opened by Dr. W. F. J. Whitley). Camp Drainage, &c. (opened by Mr. W. H. Beswick). 2.15 P.M., Visits will be made to the Swindon Maternity and Infant Welfare Hospital.

EDITORIAL NOTICES.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

We cannot prescribe or recommend practitioners.

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. Ayres, Liverpool; Messrs. Claudius Ash, Sons, and Co., Lond.; Dr. G. R. Anderson, Southport; Dr. E. L. Ash, Newbury; *Answers*, Editor of; Col. J. G. Adami, A.D.M.S.
B.—Mr. C. H. Bridle, Clacton-on-Sea; British Science Guild, Lond., Sec. of; Major A. S. G. Bell, R.A.M.C.; Capt. W. Brown, R.A.M.C.; Major J. S. Bury, R.A.M.C.; Lieut.-Com. G. E. Beer, R.N.V.R.; Messrs. Barimar, Ltd., Lond.; Dr. A. G. Bateman, Lond.; British Drug Houses, Ltd., Lond.; British Orthopædic Association, Manchester, Hon. Sec. of; Dr. W. B. Brownlie, Blackburn; Dr. N. Bardswell, Lond.; Mr. H. Blakeway, Lond.
C.—Cumberland and Westmorland Asylum; Major W. A. Chapple, R.A.M.C.; Dr. E. L. Collis, Lond.; Dr. H. P. Cholmeley, Forest Row.
D.—Dr. V. Dickinson, Lond.; Capt. A. B. Dunne, R.A.M.C.(T.); Major-Gen. Sir Bertrand Dawson, G.C.V.O., C.B.; Prof. J. S. C. Douglas, Sheffield; Dr. L. Drage, Hatfield.
E.—Surg.-Gen. G. J. H. Evatt, C.B.; Mr. D. L. Eadie, Edinburgh; Eugenics Education Society, Lond.; Major R. Eager, R.A.M.C.(T.).
F.—Sir R. Fox Symons, K.B.E., Lond.; Factories, Chief Inspector of, Lond.; Capt. F. Fraser, R.A.M.C.
G.—Dr. A. G. Gibson, Oxford; Glasgow, Medical Officer of Health of; Capt. M. Greenwood, R.A.M.C.(T.)
H.—Mr. C. Higgens, Lond.; Major A. J. Hall, R.A.M.C.(T.); Major A. T. Henderson, C.A.M.C.; Prof. J. Hutchinson, Lond.; Dr. T. Horder, Newport; Prof. R. Howden, Newcastle-on-Tyne.
I.—Insurance Committee for the County of London.
K.—Dr. W. Kidd, Alum Bay.
L.—Dr. M. Lipinska, Lond.; Messrs. Lea and Febiger, Philadelphia; Local Government Board, Lond., Medical Officer of; Cpl. A. C. Lomax, R.A.M.C.(T.); Mr. J. B. Lamb, Lond.
M.—Dr. R. Morton, Lond.; Mr. J. Y. W. McAlister, Lond.; The Medical Directory, Lond., Editors of; Metropolitan Hospital Sunday Fund, Sec. of.
N.—Miss J. Neil-Kerrison, Smethwick.
P.—Dr. Eric Pritchard, Lond.; Mr. R. H. A. Plimmer, Lond.; Professional Classes War Relief Council, Lond.; Dr. O. F. Pedroso, Lond.; Mr. J. D. Pennell, Merton Park; Comtesse Michel de Purredon, Tours.
R.—Royal Society, Lond.; Royal Institution, Lond.
S.—Dr. R. H. Steen, Dartford; Prof. W. Stirling, Manchester; Dr. H. R. Spackman, Wolverhampton; Dr. R. B. P. Squibbs, Lenton; Messrs. G. Street and Co., Lond.; Mrs. K. Senter, Edinburgh; Society of Apothecaries of London, Sec. of.
T.—Dr. C. H. Thatcher, Edinburgh; Dr. J. Tatham, Oxted; Dr. H. J. Thornton, Lond.
U.—University of Manchester; University of Glasgow; University of Durham, College of Medicine, Newcastle-on-Tyne.
W.—Capt. R. Wade, R.A.M.C.; Dr. F. J. Waldo, Lond.
X.—Xerxes.
Z.—Dr. T. Zangger, Zurich.

Notes, Short Comments, and Answers to Correspondents.

"NO BLIND PEOPLE, BUT ONLY NORMAL PEOPLE WHO CANNOT SEE."

Taking the above statement as his text, Sir Arthur Pearson, chairman of the Blinded Soldiers' and Sailors' Hostel, St. Dunstan's, Regent's Park, who presided at the seventh of the series of lectures on first-aid at the College of Ambulance (3, Vere-street, London, W.), on June 27th, in introducing the lecturer, Mr. A. Hugh Thompson, surgeon to the Western Ophthalmic Hospital, gave a stirring account of the work which is being done at his institute, where there are at present some 600 injured men from the front being educated. Already 500 have been sent out to every part of the British Empire happy, cheery, and contented, and most of them earning more money than they were able to do before their sight was injured. Colonel Bruce Porter, the commandant at the 3rd West London General Hospital, had been so impressed by the work of the masseurs supplied to him by St. Dunstan's that he had remarked it was nothing short of a shame that people who could see should do the work which blind men did so perfectly. Men were also trained as telephone operators, poultry-farmers, basket-makers, shorthand writers and typists, shoemakers, mat-makers, and joiners, the last-named being particularly expert at their work. Sir Arthur Pearson, who believes that play is as important as work, also referred to the athletic exercises and the games in which blind men excelled. Altogether the blind man left the institution much better equipped for the world than he entered it. Mr. Thompson, whose subject was first-aid in injuries and affections of the eyes, after discussing the anatomy of the eye, referred to the many injuries to which this organ was liable and the need for its protection in peace and war. More than half the injuries that blinded our soldiers, he said, were caused by small particles entering the eye, and a visor had been invented which gave the eyes protection, but he did not know how far it had been adopted. In a recent report by the Health of Munition Workers Committee it was stated that over 5 per cent. of the industrial accidents to munition workers were eye injuries, and that was, of course, a larger percentage than occurred in factories during normal times. The only possible means of preventing small particles of steel, emery, and so forth, from entering the eye was the wearing of goggles made of strong glass. He then described various simple means of rendering first aid in injuries and affections of the eye and concluded by impressing upon his audience the importance of having the eyes of children medically examined, especially in the case of young children.

RESUSCITATION FROM DROWNING.

AT a recent inquest, following a fatal boating accident on the Thames with the loss of two young lives, the City coroner, Dr. F. J. Waldo, in summing up, said that many cases of preventable deaths from drowning in the River Thames came before him officially in his two riparian districts (City and Southwark), and that many such deaths were due to the lack of proper provision for the resuscitation of people apparently drowned. The only station or place of succour for the purpose was the Thames Police Station at Waterloo Bridge, and among other places a similar station was badly wanted near London Bridge.

On the Seine at Paris numerous stations of this sort were provided, and there, with prompt treatment and the means of applying warmth in the form of hot baths and blankets always at hand, it was considered a disgrace if people, rescued after five minutes' submersion, were not brought back to life.

AMERICAN POISON PLANTS.

IN his little book on *First-Aid in Emergencies* (J. B. Lippincott. Price 6s.) Dr. Eldridge L. Eliason, assistant surgeon to the University of Pennsylvania Hospital, writes for the needs of travellers and others beyond the reach of medical aid. The chapter on poisons is remarkably well illustrated with attractive sketches of toxic plants which will be of interest to other than an American audience, although some of the names may puzzle. For instance, *Euphorbia marginata* (p. 188) is given as "Snow on the mountain," a popular name applied in this country to the white arabis. Wise counsel is interspersed throughout the book—e.g., "First-aid should never necessitate the use of a knife or needle, except when there is dire need and no physician is available," and "Carry out the rules published by the boards of health of the various communities in which you live."

CLAVADEL AS A POPULAR SANATORIUM.

WE learn from a Swiss correspondent that the Zurich Cantonal Home for Tuberculosis at Wald of 150 beds, which admits nearly 500 patients a year, is overfilled and there is a long waiting list. Efforts have therefore been made to provide another sanatorium in the Alps as a *dépendance*. A committee formed for this purpose has collected within a month over £40,000 in the canton and town of Zurich (total population 520,000), the cantonal and urban authorities both contributing large sums. The private sanatorium at Clavadel, above Davos, known to many of our readers for its magnificent situation at the opening of the Sertig Valley, has been bought, and will be opened during the present month for 100 poor and 30 paying patients.

GUIDES TO MEDICAL SERVICE AT THE FRONT.

THE arrangements of the medical service behind the lines and of the disposal of the sick and wounded are of perennial interest, and many will welcome an excellent little book entitled "Medical Service at the Front" (Lea and Febiger. 1918. Price $1.25), by Lieutenant Colonel John McCourbe and Captain A. F. Menzies, of the C.A.M.C. Their aim has been "to give the simple facts in a plain way" and Surgeon-General J. F. Fotheringham, who contributes a foreword, writes that the volume "is hot from hell's gridiron and correct in all its details." The chapters deal in succession with the R.M.O., the F.A., the A.D.M.S., and the C.C.S.—the war has taught us to think in initials—and are full of illuminating paragraphs, such as: An outstanding feature [of the C.C.S. during battle] is the "surgical team," made up of a surgeon, an anæsthetist, a nursing sister, and two orderlies, all specially qualified for their work. Usually several of these teams are sent to each clearing station behind a battle front. Numerous diagrams help the reader to visualise the arrangements described.—A useful summary of the regulations and routine of the military medical officer is given in *Hints for R.A.M.C. Officers* (Edinburgh: William Bryce. 1918. Price 1s.), by "Ramcorps," in a format suitable for the pocket, and containing the information which a newly appointed officer is likely to need in his administrative duties—e.g., the filling up of forms, signing certificates, and making reports.

THE ROCKEFELLER FOUNDATION.

AN account of the work carried out by the Foundation during the year 1917 has recently appeared. The President, Mr. George E. Vincent, reminds his readers of the many directions in carrying out the work of the institution in which the Foundation has worked for medical education and for the amelioration of conditions produced by the war. On August 13th, 1914, two weeks after war broke out, an appropriation grant was made enabling Dr. Carrel to begin his surgical work in France, while in the hospital erected on the grounds of the Rockefeller Institute for Medical Research in New York City the Carrel-Dakin method is now being demonstrated to American Army and Navy surgeons, 292 of whom attended classes in 1917. During the same period 3000 doses of serum were distributed to Government hospitals. Last year Dr. Thomas W. Salmon was deputed to visit Great Britain and to make a study of nervous diseases and their treatment in British military hospitals, his report to the Surgeon-General's office determining American Army policy in regard to these cases. Other activities of the foundation have been: Care for the victims of infantile paralysis; a crusade against tuberculosis in France; and the establishment at Johns Hopkins University of a School of Hygiene and Public Health. Steady progress has been maintained in the campaign directed against hookworm, malaria, and yellow fever, as well as in the systematic efforts to secure the enactment of sanitary legislation and to persuade governments to increase their expenditure on preventive medicine. "Dispensaries and physicians have of late been peacefully penetrating areas of the Philippine Islands and demonstrating the fact that for the purpose of placating primitive and suspicious peoples medicine has some advantages over machine guns," and in China hospitals have been subsidised and travelling scholarships granted. The report concludes: "When at last peace comes it cannot quickly bring universal confidence and goodwill; there may be years of suspicion and bitterness, of misunderstanding and recrimination; there is sure to be keen industrial and commercial competition. Is it too much to hope that such work as the Foundation is doing in many parts of the world may tend at least to emphasise the common interests of mankind in turning science from the destruction to the healing and the happiness of men?"

M.D. Durham has omitted to enclose his card.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The Goulstonian Lectures
ON
MODERN VIEWS ON DIABETES
AND ON THE SIGNIFICANCE OF ACIDOSIS IN DISEASE.

BY E. P. POULTON, M.A., M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, GUY'S HOSPITAL.

LECTURE III.*

ACIDOSIS IN DISEASE.

MR. PRESIDENT, LADIES AND GENTLEMEN,—In the first lecture Barcroft's definition [2] of acidosis was given; it is an increase of acid relative to basic radicles in the blood, the CO_2 of the blood not being considered. It has nothing to do with the final reaction of the blood—i.e., its hydrogen ion concentration.

MECHANISMS OF BODY IN DEALING WITH ACIDOSIS.

Under many physiological conditions of acidosis the hydrogen ion concentration of the blood remains constant, because the CO_2 content of the blood is reduced to compensate for the increase in acid radicles—a condition of "compensated acidosis." In other circumstances the CO_2 may not be lowered sufficiently, when an "uncompensated acidosis" results—i.e., the hydrogen ion concentration is increased. In other cases the acidosis is "over-compensated" when the respiratory centre is over-active, and washes out more CO_2 than is necessary, so that the blood becomes more alkaline than normal. This often occurs in diabetic acidosis of moderate severity.

This condition of over-compensation implies an alteration in respiratory control, so that over-ventilation occurs and the blood becomes alkaline, or, what is a different way of expressing the same thing, the excitability of the respiratory centre is increased, so that it reacts to a lower concentration of hydrogen-ions than usual. The variation in the excitability of the respiratory centre has been denied by Haldane, but there is evidence that it occurs normally. Straub [1] has shown that the alveolar CO_2 is distinctly higher during sleep in the middle of the night than it is in the day-time, which suggests that the respiratory centre, like the heat regulating centre, has a regular diurnal periodicity.

Under ordinary circumstances the respiratory centre is extremely sensitive to small additions of acid to the blood, and maintains the normal reaction of the blood by a fall in the alveolar CO_2. This fall and the consequent diminution in the CO_2 combined in the blood, the so-called alkali reserve, is one of the most important mechanisms the body possesses for preventing the rise in H ion concentration of the blood.

It is well known that the urine contains monosodium and disodium phosphates, although in the blood they are chiefly present in the red corpuscles. Acid is got rid of through the kidney by the conversion of the alkaline disodium phosphate into the acid monosodium phosphate, and by this process the hydrogen ion concentration of the urine is increased, though to nothing like the same extent as if the unaltered acid had been excreted in the free state. The phosphates act as "buffers," which damp down the effect of the addition of acid.

The third mechanism is in the formation of ammonia and its excretion combined with acid.

ALTITUDE AND EXERCISE.

One of the earliest investigations on acidosis in human beings was carried out by Barcroft [2] on the effect of altitude.

Ward [3] had shown previously by investigations on himself that on the top of Monte Rosa his alveolar CO_2 was lowered, and this effect persisted for many days after his return from the ascent. The explanation offered was that an acidosis was present, which required increased pulmonary ventilation. The beneficial effect of this was the fact that the oxygen pressure in the lungs was thereby increased; it was a mode of adaptation making it possible to exist in a rarefied atmosphere.

The actual acidosis was proved by Barcroft by means of the blood dissociation curve, described in Lecture II. He further showed by measuring the alveolar CO_2 that the acidosis was a compensated acidosis.

It has been already stated that the acidosis at high altitudes may be looked upon as a process of acclimatisation to enable the organism to live in a rarefied atmosphere. A good deal of attention has been paid to the nature of this acidosis

Ryffel showed it was not due to lactic acid. Hasselbalch [4] found in various people a sudden diminution in the ammonia excretion and an unusually alkaline urine as the immediate effect of reducing pressure in an airtight chamber. His explanation is that the acidosis is not due to the formation of a new acid, but that it is a relative acidosis due to deficiency of bases, brought about by the diminution in production of the endogenous base ammonia. This discovery provides a new outlook on the subject. Under conditions when an acidosis is favourable to the body, such as may occur in oxygen want, it may be deliberately brought about by diminishing the production of ammonia and making the urine more alkaline.

In the last lecture it was shown that in muscular exercise not only was there an acidosis, but the acidosis was uncompensated.

Barcroft has shown that the uncompensation becomes greater if the exercise is taken at an altitude. This acidosis has been shown by Ryffel to be due to the formation of lactic acid. Thus, it is a different type from that which the effect of altitude produces when the body is at rest.

PREGNANCY AND ECLAMPSIA.

The possibility that the normal process of pregnancy is associated with an acidosis was suggested independently by Hasselbalch and by Leimdorfer, Novak, and Porges. They found that the alveolar CO_2 was lowered.

The Viennese observers, as a result of work on 15 cases, claimed that the diminution in the alveolar CO_2 was one of the earliest signs of pregnancy.

A series of observations by Hasselbalch and Gammeltoft [5] on a case showed a distinct fall in the alveolar CO_2 on the first occasion when menstruation ceased, and the alveolar CO_2 fell gradually to 30 mm. just before the birth of the child.

The problem as to whether the fall in alveolar CO_2 was really due to an acidosis was settled by measuring the hydrogen ion concentration of the blood taken shortly before and after child-birth. In five cases the mean alveolar CO_2 before birth was 32·3 mm., and the mean value after birth was 38·1, a rise of nearly 6 mm.

The ph of two samples of blood taken before and after child-birth was determined, and at the corresponding alveolar CO_2 pressures the mean values were 7·43 and 7·44. This means that during pregnancy there is a fully compensated acidosis.

Hasselbalch and Gammeltoft observed a few cases of eclampsia.

The alveolar CO_2 was not measured. In two cases which were not very severe the fixed acidity was not abnormally increased; with 40 mm. CO_2 the values of ph were 7·38 and 7·36; the corresponding mean value for the five normal pregnancies was 7·39. In the two severe cases the values were 7·19 and 7·23, values so acid that the authors doubt whether the alveolar CO_2 would have been reduced sufficiently to compensate. Unless this had been the case the acidosis would have been uncompensated. Thus the cases resembled the condition in uræmia, to be described later.

RELATION BETWEEN AMMONIA EXCRETION AND ACIDITY OF URINE.

The relation between the ammonia excretion and the acidity of the urine has been recently investigated by Hasselbalch. [6]

As a general rule he found that an acid urine was accompanied by an increased ammonia excretion, and vice-versa. There is an obvious difficulty with regard to the ammonia excretion, and that is that the amount of ammonia formed depends, to a large extent, on the protein metabolism. He excluded this factor by using the ratio between the ammonia nitrogen and the total nitrogen expressed as a percentage.

If the ph of samples of urine passed at different times during the day on a mixed diet are measured the acidity is always diminished 3–4 hours after a meal, and increases again immediately after the meal. The maximum carbohydrate metabolism occurs 3–4 hours after a meal, and this diminishes the acidity. The latter has nothing to do with the reaction of the gastric juice.

The ammonia ratio always increases as the ph diminishes (i.e., as the acidity increases), and if the corresponding values for these two factors are plotted against one another, the points all lie on a rectangular hyperbola. The mean value for the ph of the urine is 5·8, and the corresponding ammonia ratio, "the reduced ammonia ratio," for normal people lies between 2·2 per cent. and 5·3 per cent.

This relationship is not altered by taking large quantities of water, salt, or dilute HCl, and is independent of diet. It is constant for the individual, but there are slight seasonal variations. In pregnancy, after severe muscular work, in fever, and in diabetic acidosis, the reduced ammonia ratio is increased and the ammonia figures corresponding to other ph's are correspondingly increased, the points still forming a hyperbola the position of which has been altered.

The increased formation of ammonia may be due to a specific formation of ammonia from protein, and this power of formation may well vary in different people. The object of the formation is obvious: it spares the alkali reserve of the blood, it prevents the unnecessary excretion of phosphates—the only other way in which acid can be removed from the blood.

ANÆSTHESIA AND SHOCK.

Emphasis has been laid on the fact that acidosis is accompanied by increased pulmonary ventilation, and conversely any case of hyperpnœa would suggest the possibility of an acidosis being present. It is remarkable in how many different conditions this has been proved to be the case.

In anæsthesia, particularly when open ether is used, the respiration is stimulated, and there is a fall in the alveolar CO_2. However, Morriss [7] has shown that under these conditions there is a diminution of the alkali reserve of the plasma, which indicates that some fixed acid is present in excess.

Yandell Henderson's well-known theory of shock attributed the condition to acapnia—a loss of CO_2.

* Lectures I. and II. were published in THE LANCET of June 22nd (p. 883) and 29th (p. 895), 1918.

Recent experiments of his[8] were carried out as follows. An anæsthetic like morphia was chosen which did not produce acapnia on its own account. The shock was produced by opening the body and handling the animal's intestines; a rapid fall in the alkali reserve was noticed, coinciding with the hyperpnœa. This would suggest that the acapnia was a secondary effect of the acidosis in this type of shock.

In other cases the hyperpnœa is presumably primary, such as the hyperpnœa associated with pain, but even in this condition a fall in the alkali reserve was noticed, and Henderson suggests that this acidosis is a secondary phenomenon to counteract the acapnia produced by the hyperpnœa. If no acid were produced the deep breathing would wash out the CO_2, and the individual might become asphyxiated owing to the removal of the CO_2, the normal stimulus to respiration.

Surgical shock can be produced in many different ways. Cannon has found that there is an acidosis present; but there is no proof that the acidosis is the cause of shock. It may be a compensatory mechanism to guard against acapnia, as Henderson has suggested; or a more likely explanation is that through failure in the circulation acid products are formed due to deficient oxidation, and these produce the acidosis, which is therefore the result of the shock and not its cause.

HEART DISEASE AND URÆMIA.

One of the most striking examples of dyspnœa is afforded by conditions of failing heart, whether it is the heart itself which is primarily at fault, as in simple valvular disease, or whether there is a renal element added to it, which forms a complex usually described as cardio-renal disease.

The first detailed investigation on this subject was carried out by Lewis, Ryffel, Wolf, Cotton, and Barcroft.[9] The subject is complicated because the separation of cases of this kind into different clinical groups is difficult.

The main conclusions of the paper, which Barcroft and Lewis[10] tried to confirm in a later paper, was that in cardiac failure from simple valvular disease there was no acidosis present, but that the dyspnœa was due to excess of CO_2 circulating in the blood. A further point was their refusal to define the meaning of the term uræmia, which they looked upon as too vague a term to be of any value.

Uræmia.

However, the term uræmia can be applied to, and should be restricted to, a very definite type of case in which there is retention of urinary products, and this retention can easily be determined by measuring the percentage of urea in the blood. There is evidence that urea is in itself poisonous, giving rise to drowsiness and coma associated with muscular twitchings.

Uræmia is roughly of two clinical types.

The commonest type is the case with fibrosis in the kidney and a high B.P., and during the attack the urea in the blood may reach a value of ten times the normal—i.e., 3 parts per 1000. If the patient recovers the urea falls, but owing to the damaged kidney it always remains higher than normal. The picture is the same whether the condition arises in the course of Bright's disease or whether it is due to sepsis in the urinary tract.

The second type is the uræmia of acute nephritis, and there may be here some other intoxication also present, due presumably to the acute infective process in the kidney. Though there is some retention of urea in acute nephritis, it is nothing like so great as in the fibrosed kidney,† and the probable explanation is that the body has accustomed itself to a large dose of urea in the blood in the latter condition.

The value of K by Barcroft's method was determined by Poulton and Ryffel[11] in four cases of uræmia in which the blood urea was about 10 times the normal concentration.

The alveolar CO_2 was low; there was an acidosis, and at the same time values for K suggested the hydrogen ion concentration was increased. Schlayer and Straub[12] had already observed that the alveolar CO_2 was diminished in uræmia, and had suggested there was an acidosis, but had not given any proof of it.

In order to get over the objection that the value for K may be affected by other factors than hydrogen ion concentration in pathological conditions, Donegan, Parsons, and Poulton‡ have investigated three other uræmic cases, measuring the hydrogen ion concentration of the blood directly.

In one obviously mild case, a man (urea in blood 0·46 per 1000, alveolar CO_2 of 31 mm., i.e., slightly reduced), with no perceptible hyperpnœa while sitting up in bed, there was a slight fully compensated acidosis. The ph at the alveolar CO_2 pressure was 7·40—a normal figure.

In a second man the urea in the blood was 0·54 per 1000, i.e., slightly raised, the alveolar CO_2 was 34 mm., and the ph was 7·39—again a slight compensated acidosis. The patient was walking about and feeling quite fit.

In a case of advanced uræmia, with the patient very dyspnœic and unconscious just before death, both the value for K (0·000055) and for ph (6·92) showed actual acidity. As far as I know, this is the most acid case that has ever been recorded. The urea in the blood was 4·0 per 1000.

The conclusion to be drawn is that in uræmia, when the dyspnœa at rest is marked, there is an uncompensated acidosis.

† However, Dr. Ryffel informs me that in two children with nephritis (ages 1 and 4) he has found quite high values for the blood urea.

‡ Not yet published.

Simple Cardiac Cases.

The remarkable feature about the dyspnœa of valvular disease of the heart is that in the milder cases, while the patient is quiet, the breathlessness is absent, but as soon as any exertion is taken the dyspnœa becomes obvious.

Peabody,[13] following Siebeck, explains this condition by the lowered vital capacity of the patient. This is determined by a spirometer. The patient inspires as deeply as possible and the total air consisting of a full inspiration and a full expiration is measured in the spirometer. In heart cases with failing compensation, much lower values are obtained than in healthy people, and the vital capacity becomes normal as the case improved. Dyspnœa on exertion will be due to the fact that in healthy people the pulmonary ventilation is increased without effort, but when the movements of the chest are restricted, as in heart failure, increased pulmonary ventilation will be difficult. This is probably only one factor in the dyspnœa.

Barcroft and Lewis[9 10] showed by means of the blood dissociation curve that in the mild type of case there was no acidosis. Peters,[14] later, came to the same conclusion, by determining the alkali reserve of the blood by Van Slyke's method.

Barcroft and Lewis argue from their results that in all cases of simple cardiac dyspnœa associated with valvular disease there is no acidosis.

But this is too sweeping a statement, because on analysing their cases it is found that it is only in the milder cases that the absence of acidosis is noted. This is shown by the following remarks from the two papers.[9 10]

Case 13 "was convalescent when the examination was made." Case 14 "had improved to some extent when the special observations were made." Case 15 "was convalescent." Case 7, "there was no distress, breath could be held 15 seconds." Case 8, "breath could be held 20 seconds." Case 9, "respirations were 25 per minute, but not distressed."

On the other hand, some of the simple cardiac cases did show a marked acidosis when the dyspnœa was severe, and, although Barcroft and Lewis considered that there was a renal element present, there was little evidence of this.

The following are examples:—

Case 2: Mitral stenosis, auricular fibrillation. "The breathing is very laboured and rapid; there is absolutely no reserve. P.M., kidneys show little change apart from congestion."

Case 5: Aortic disease and aneurysm; Cheyne-Stokes breathing. "Distress was considerable. P.M., kidneys congested, surface smooth, and capsules stripped easily."

Case 6: Aortic disease. "Breathing laboured, 40 per minute. P.M., kidneys congested, little or no fibrosis, epithelium swollen and granular."

The absence of any renal element was shown by the fact that the urea in the blood was not raised, and further microscopic examination did not show any extensive glomerular destruction. The albuminuria may be attributed to the renal congestion, which was always prominent in the case.

The conclusion to be drawn is that cardiac dyspnœa, if mild in degree—i.e., in the earlier stages of failure of compensation—is not associated with an acidosis, but that in serious cases an uncompensated acidosis occurs—i.e., the hydrogen ion concentration of the blood is increased.

This statement is borne out by a case of my own. T. H., a young man, was admitted on Jan. 9th, 1915, with rheumatic mitral stenosis and cardiac failure. The failure had been threatening for some months previously; his breathing was greatly distressed. He was relieved to some extent by venesection. Red cells 6,700,000 per c.mm., Hb 108 per cent., alveolar CO_2 23 mm. The blood dissociation curve at a pressure of 22·7 mm. CO_2 gave a K of ·000136. This case showed, a day or two before death, a severe uncompensated acidosis.

Cardio-renal Cases.

The remaining cases described by Lewis and Barcroft were not characterised by any obvious valvular lesion, and they were not cases of rheumatic heart disease.

They are perhaps usually described as cardio-renal cases. They all showed an uncompensated acidosis when the dyspnœa was severe. In only one case was the urea in the blood considerably raised above normal, when it was 1·07 parts per 1000. These patients were very prone to attacks of Cheyne-Stokes breathing. Six of the cases died and post-mortem examinations were made. In all these there was some evidence of myocardial degeneration, and all of them showed atheroma of the coronary arteries. In only two cases was there any extensive destruction of Malpighian corpuscles, and in one of these the blood urea was 0·4 per 1000 during life—i.e. slightly raised; in the other case the blood urea was not determined, but to judge from the appearance of the kidney it would have been high.

Hence in the majority of these cases there was not the same rise in the blood urea that was present in Poulton and Ryffel's cases, and so uræmia could not be said to be present.

The most characteristic point in the post mortems was the evidence of long-continued cardiac failure, the organs, particularly the liver, showing congestion and being enlarged. This, coupled with the myocardial changes, suggest that these cases are primarily failure of the cardiac muscle, and there is no reason to differentiate the nature of the uncompensated acidosis in these cases from the uncompensated acidosis present in the later stages of rheumatic and valvular heart disease. Doubtless in all cases of pronounced heart failure there are secondary changes in renal function.

Hale White, Ryffel, Poulton, Johnson, and Chisolm[15] investigated in considerable detail a case belonging to the same clinical group, but in which the Cheyne-Stokes breathing was extremely marked and lasted for weeks.

In this condition there is a considerable variation in the composition of the alveolar air at different periods in the respiratory cycle, a was first described by Pitt, Pembrey, and Allen.[16] Just at the end of the apnœic period the CO_2 pressure is highest, while the oxygen pressure is lowest; at the end of the dyspnœic period the condition is reversed. The result is that the respiratory centre is, at the end of the apnœa, supplied with blood containing CO_2 at 30 mm. pressure and at the beginning of the apnœa the CO_2 pressure in the blood has fallen to 16 mm.

Two determinations of K were made. At 16 mm. CO_2 K was 0·000261, which is a normal value, and at 30 mm. K was 0·000157, a value much more acid than normal. Hence, when the respiratory centre was being supplied with abnormally acid blood respiration started, whereas when the acidity was reduced to normal respiration stopped. The conclusion follows that in this case of Cheyne Stokes respiration the respiratory centre had a diminished excitability, because it only reacted to a more acid blood than normal and ceased acting when the hydrogen ion concentration was normal.

The urea in the blood was about three times the normal—0·75 per 1000. The lactic acid in the blood was not increased.

Post-mortem examination showed a nutmeg liver; the kidneys showed arterio-sclerotic changes, but the glomeruli were normal. The dorsal nucleus of the vagus showed advanced chromatolysis and atrophy of the cells; this is interesting, as this nucleus is regarded as the respiratory centre, and the patient had Cheyne-Stokes respiration. However, Johnson has found similar changes in all cases where there has been a terminal dyspnœa of some days' duration; so the significance is doubtful.

Two Types of Case.

A summary of these conditions is as follows. There are two distinct types of case—the uræmic with the high blood urea and the case showing simple cardiac insufficiency. The uræmic case tends to show acidosis in quite an early stage, and this is compensated to start with. In the final stages the acidosis is uncompensated, and extremely acid values may be found. In the later stages of simple cardiac failure there is an uncompensated acidosis. The cardio-renal case is usually a mixture of both these types. There is often obvious cardiac failure and the blood urea is raised to some extent. In the cardio-renal case there is often another independent condition—viz., the liability to Cheyne-Stokes respiration. This is due to a diminished excitability of the respiratory centre, which is probably due to sclerosis of the arteries supplying the centre, so that there is some failure in the supply of blood to the centre.

Nature of the Acidosis.

What is the nature of the acidosis?

It certainly is not lactic acid, and so far no other acid has been found. If it is permissible to speculate, I would point to the analogy of the acidosis observed at high altitudes, which is brought about by a diminished production of ammonia and has the object of providing the body with a larger supply of oxygen by greater ventilation of the lungs. It may very well be that a similar state of things occurs in severe cardiac dyspnœa. There is a call for more oxygen, and an artificial acidosis is created to supply the demand.

Cause of Uncompensation in Later Stages.

Why does this acidosis become uncompensated in the later stages?

It may be that lack of oxygen renders the respiratory centre less sensitive to CO_2, and so the hydrogen ion concentration increases, or the acidosis may become so great that it is impossible to excrete the CO_2 sufficiently quickly to keep pace with it. This second explanation is difficult, because in diabetic coma the alveolar CO_2 falls much lower than in cardiac dyspnœa, and yet the acidosis still remains compensated.

There is yet a third possible explanation.

Hooker, Wilson and Connett[17] have shown by animal experiment that CO_2 has a specifically greater stimulating effect on respiration than other acids—e.g., HCl. For a given H ion concentration the pulmonary ventilation was greater if the acid was CO_2 than if it was HCl.

In uræmic acidosis there is a diminution in the CO_2 and an increase in fixed acid. Hence the mixture will be less stimulating, and a higher H ion concentration will be required. It follows that an increasing acidosis will become more and more uncompensated. Diabetic acidosis apparently provides a difficulty, because even in severe stages the acidosis remains compensated. But it will be remembered that there is evidence that the aceto-acetic ion is itself a specific stimulant to respiration, and if its action is equal to the CO_2 it will make no difference if there is an increase of aceto-acetic acid and a decrease in CO_2. The stimulating action will remain the same, and however great the acidosis it will still remain compensated.

The specific stimulating action of CO_2 may provide the explanation of the great difference found in pulmonary ventilation in the most serious cases of dyspnœa, and the pulmonary ventilation in muscular work.

It is rare to find a higher pulmonary ventilation in disease than 20 litres per minute. The normal at rest in bed is about 6 litres. In muscular work enormous values of 60 or 80 litres per minute are obtained. It may be the specific stimulating action of CO_2 that admits of these huge ventilations taking place in muscular work.

ACIDOSIS IN OTHER DISEASES: GAS GANGRENE.

Acidosis has been described in various other diseases.

In septic febrile states Fridericia and Olsen[18] showed that the alveolar CO_2 was diminished. They inferred that an acidosis was present; but there is no proof without measurement of the alkali reserve.

Rogers[19] has described an acidosis in the uræmia of cholera, which is to be expected.

Barcroft and Lewis[19] showed the presence of acidosis in pneumonia, in a case of pneumothorax and exophthalmic goitre with distressed breathing, and in a case of paroxysmal breathlessness.

Wright and Fleming[20] have published results indicating the existence of an acidosis in gas-gangrene patients and advocating injections of sodium bicarbonate as a therapeutic measure.

Joffe and Poulton § have investigated the subject by observations on puppies infected with *Vibrion septique*. Oxyhæmoglobin dissociation curves at a constant pressure of CO_2 (37 mm.) were determined before and after the infection. No acidosis was found in the blood when the animal was constitutionally severely affected, but there was some definite acidosis in the blood taken from one animal immediately after death.

Wright used two methods:

He titrated the serum of gas-gangrene patients with standard acid, and he measured the hydrogen ion concentration of the serum by Marriotte's method after the CO_2 had been shaken out of it. Both methods give a measure of the fixed acids of the blood, which is increased in acidosis. Neither of the methods gives the hydrogen ion concentration of arterial blood—i.e., the blood at the alveolar CO_2 pressure.

There is no doubt about the acidosis Wright and Fleming found in their patients, and in addition many of them showed the hyperpnœa that would be expected. The main problem is to determine its importance, and in this question the knowledge of the effect of sodium-bicarbonate injections will be of value.

Wright used solutions of 500 c.cm. containing 5 per cent. sodium bicarbonate. In many cases the immediate effect of the solution was all that could be desired; the patient, although cold and pulseless, revived. An operation could often be performed, but death occurred in the majority of cases some hours later, very often in spite of a second injection of sodium bicarbonate. The authors themselves are not by any means enthusiastic about the treatment.

There is one other piece of evidence on this subject:

That is from Bull's recent work[21] on the preparation of the toxin from the bacillus of Welch, which he used in preparing his antitoxic serum. The acidity produced by the growth of the organism bears no relation whatever to the virulence of the culture.

These views bear out Joffe and Poulton's results, which indicated that the acidosis was a terminal result of the infection, and was not probably of much significance. It is impossible to help feeling that equally good results would have been obtained by Wright and Fleming if they had given intravenous injections of some neutral salt instead of sodium bicarbonate. Similarly it might be suggested that the equally brilliant results obtained occasionally in diabetic coma would also have followed a saline injection. In fact, Hilton Fagge published one such case. At the same time it must be admitted that when an acidosis due to production of acid has been proved the most rational method to adopt, if intravenous injection is assured, is to add some alkali to the fluid.

CONCLUSION.

And now the time for these lectures is drawing to a close. The attempt has been made to explain acidosis in two ways. It is either the result of increased production of acid, when the body uses the means at its disposal to compensate for its presence, and so prevent the rise in hydrogen ion concentration of the blood; or acidosis is of itself of benefit to the organism and is deliberately produced by the organism by modifying the action of the kidneys and liver—i.e., the formation of ammonia and the excretion of alkali.

These two types of acidosis will be similar to one another in the fall of the alveolar CO_2 and of the alkali reserve of the blood. They will differ from one another in the character of the urine. In one case the ammonia and the acidity will be increased, and in the other both will be diminished. Acidosis may be expected whenever the ventilation of the lungs is increased, and it is difficult to believe its existence except to a minute extent when there is no altered respiration. It is a very common condition and seems often to occur as a terminal phenomenon just before death. This was shown by Whitney, who found a blood acidosis in most cases after death, and particularly in those cases which had suffered from some infection.

Acidosis has been invoked as an important factor in certain diseases—scurvy, skin diseases, rickets. In the last-named condition it has been gravely suggested that the acidosis dissolves the lime salts from the bones. This would obviously be impossible without a rise in hydrogen ion concentration in the tissue fluid surrounding the bones. In

§ Not yet published.

none of these conditions is there trustworthy evidence that an acidosis exists; in fact, from the absence of respiratory symptoms its presence is extremely unlikely.

The last 10 years have made a great difference in our knowledge of the subject, but even now it is hardly out of its infancy. Workers of many nations have contributed to the advance. I do not think that we in this country need be ashamed of the share we have had in it. There are three names to whom before all others the modern conception of acidosis is due. They are Hasselbalch, of Copenhagen, and Haldane and Barcroft, of the Oxford and Cambridge schools.

THE

ABSENCE OF THE *BACILLUS INFLUENZÆ* IN THE EXUDATE FROM THE UPPER AIR-PASSAGES IN THE PRESENT EPIDEMIC.[1]

BY CAPTAIN T. R. LITTLE, C.A.M.C., O.C., CAPTAINS C. J. GAROFALO AND P. A. WILLIAMS, C.A.M.C.

(*From No. 1 Canadian Mobile Laboratory.*)

Is the present widely spread epidemic one of influenza or is it something new?

In recent years influenza has been only endemic, hence there has been little opportunity to study its causative organism by modern laboratory methods. The last great epidemic began about 1889, and lasted until about 1892. It rapidly spread over the civilised world. The present epidemic is also widely spread. Several camps have experienced it. A few weeks ago the —— area began to have cases. It rapidly spread through bodies of men. One reserve battalion had about 8 per cent. of its men develop the symptoms during 36 hours. Another reserve had 300 cases in four days. One camp reported an average of 40 cases per day for 12 days. Up to the present in the areas covered by this laboratory there have been about 1000 cases.

Symptoms.

Clinically the disease simulates influenza. It is an acute febrile infectious condition of three or four days' duration. The most striking symptoms are: Sudden onset with chills, severe headache with pain in cervical, dorsal, and lumbar regions, also pain in limbs and general malaise. The face is somewhat flushed and herpes labialis is to be noticed in a few cases. The fever soon attains its maximum, which varies from 99° to 102°. Several cases were observed in which the maximum temperature was 103° to 104°. Usually the highest point is reached on the second day, then follows an abrupt crisis, and on the fourth day the man feels practically normal. Many cases develop a cough, harsh in nature, with a thick sputum, scanty in amount and constant in appearance. It is not the greenish sputum of influenza proper, but is of a white mucoid nature. The urine is somewhat scanty, the appetite poor, and the bowels are constipated.

It will be noted: (1) That the pyrexia is of shorter duration; (2) that the total course of the disease is shorter; (3) that the gastro-intestinal symptoms are slighter than in the form of influenza due to the *Bacillus influenzæ*, commonly called Pfeiffer's bacillus. It is also noteworthy that convalescence is rapid and that as yet we have noted no cases of relapse, recurrence, or of complications. It must be remembered that the cases under our observation were young healthy soldiers in prime physical condition.

[1] A paper read before the —— Area Medical Society on July 2nd, 1918.

Owing to the rapidity of the spread we had no doubt that the causative organism was carried in the upper air-passages and that the infection was passed on by direct personal contact, drinking utensils, &c. This laboratory undertook an investigation of the epidemic.

Results of Laboratory Investigation.

The following examinations were carried out in 20 cases: (1) Urinary examinations; (2) leucocyte counts; (3) leucocyte differential counts; (4) blood cultures; (5) bacteriological examinations from naso-pharynx, throat, and sputum. The following are the results.

Urine.—Somewhat scanty and typically febrile, with a fair diminution of the chlorides; otherwise normal.

Blood counts.—Contrary to our expectation, we found that there is very little leucocytosis, the highest being 13,000 per c.mm., the average being 8000 per c.mm. The highest polymorphonuclear proportion was 60 per cent., the lowest 35 per cent., the average 47·5 per cent. We found that there was present a proportional lymphocytosis, the highest being 60 per cent., the lowest 32 per cent., the average 43·6 per cent. The blood picture is one of very little, if any, leucocytosis, with a decided increase in the relative number of small lymphocytes.

Blood cultures.—These all proved sterile.

Bacteriological examinations.—These were very interesting. We observed in all the cases studied that direct smears from the naso-pharynx, throat, and sputum contained among the organisms present one which was in outstanding predominance. It was a very small Gram-positive diplococcus, distinctly flattened on its apposing sides. Some of these smears contained no other organisms. In no smear examined were we able to discover the *Bacillus influenzæ*.

Cultures were made in these 20 cases from the two locations mentioned and from the sputum. Legumin serum agar plates were used. All the plates showed among other colonies one sort which was exceedingly abundant. In fact, in a few naso-pharyngeal plates it was in pure culture. In all the plates this colony was present vastly in excess of any other. It is a small, transparent, granular colony, strikingly like that of streptococcus. In each plate it proved to be composed of the same organism that we had noted in the preliminary direct smears. From no plates were we able to obtain colonies of *Bacillus influenzæ*.

It may be contended that this is due to the fact that we did not use media containing whole blood. It has been our experience that *Bacillus influenzæ* grows abundantly on legumin serum agar. We frequently obtain it when making routine bacteriological examinations from the naso-pharynx.

This diplococcus, we find, grows with reluctance on ordinary media. It prefers those containing serum. Hæmoglobin also accelerates its growth. It grows abundantly on Löffler's blood serum, legumin serum agar, blood agar, and in bouillon containing a little blood. On blood agar plates there is no hæmolysis, but in blood bouillon the erythrocytes appear broken up. The organism does not split either dextrose, lævulose, maltose, lactose, saccharose, or mannite. It has a slight tendency to anaerobic growth, and in fluid media containing blood a distinct tendency to chain formation.

When inoculated intraperitoneally it proved non-pathogenic to mice. The temperature of some was raised slightly for 24 hours. They showed a slight but distinct roughening of the hair. These reactions, however, might very well be due to the introduction of foreign protein. Further animal inoculation is being undertaken.

It will be noted that we found this organism in universal predominance and that we were able to cultivate it in the laboratory, thus fulfilling Koch's first two postulates. His final postulate we have not as yet, however, fulfilled.

Conclusion.

In conclusion, we wish to point out that although this epidemic has been called influenza for the want of a better name, yet in our opinion it cannot properly be considered such for the following reasons:—

1. The clinical course, though similar to that of influenza, is of very short duration, and there is, so far as we have observed, an absence of relapses, recurrence, or complications.
2. The present epidemic is not characterised by a sharp leucocytosis and polynucleosis, but rather by a very slight leucocytosis with a proportional lymphocytosis of the small mononuclear variety.
3. The organism of influenza—viz., *Bacillus influenzæ*—was in all cases absent and there was present with no exception a Gram-positive diplococcus.

Of course, it has long been recognised that attacks of so-called influenza are often due to organisms other than the *Bacillus influenzæ*. Many have been indicated. The purpose of our work was to determine the causative organism of the present epidemic. We consider this to be the above-mentioned diplococcus.

ON SOME UNUSUAL FORMS OF EPIDEMIC DISEASE.[1]

BY A. K. CHALMERS, M.D.GLASG., F.R.F.P.S., D.P.H.,
MEDICAL OFFICER OF HEALTH, GLASGOW;
R. M. F. PICKEN, B.Sc., M.B., CH.B.GLASG., D.P.H.,
ASSISTANT TUBERCULOSIS OFFICER AND ASSISTANT TO M.O.H., GLASGOW;
AND
A. MACLEAN, M.B., CH.B.GLASG., D.P.H.,
ASSISTANT MEDICAL OFFICER OF HEALTH, GLASGOW.

GENERAL REPORT BY DR. A. K. CHALMERS.

DURING May several incidents combined to direct attention to the occurrence of certain forms of illness associated in some instances with severe nervous symptoms and a high rate of mortality. These were isolated in their occurrence, but almost contemporaneous with certain other cases which were definitely grouped in places of employment and in residential institutions. Some of these were probably influenzal in character, while others assumed the clinical features of the Abercromby Street School outbreak of 1888.

Coincident with these occurrences the number of deaths registered in the first fortnight of May rose to 886 in place of 663 in the preceding fortnight and the rate to 20 in place of 15 per 1000. The largest increase in the grouped causes of death was ascribed to cerebral hæmorrhage and respiratory disease and the chief incidence was at ages under 25.

At this period the press was reporting cases of botulism (a form of food poisoning), and three cases admitted to the fever hospitals under other names (typhus and cerebro-spinal fever), together with one seen by Dr. Picken in consultation, presented some of the features elsewhere ascribed to this affection, but without any association with food, as a likely explanation of the illness.

Results of Investigations.

In view of these circumstances Dr. Picken conducted an inquiry into the isolated cases, and Dr. MacLean into the grouped industrial and institutional cases. These latter mostly occurred in Lanarkshire, but had relationship with certain antecedent cases in Glasgow.

In the inquiries beyond Glasgow he was associated with the public health staff of the county.

From both reports (which are appended) it seems likely that we are dealing with at least two types of affection of the nervous system apart from influenza.

In the cases investigated by Dr. Picken nervous symptoms were a predominant feature. Sometimes they took the form of rigidity of certain groups of muscles, chiefly of the arms or legs. In some the rigidity was followed by paralysis; in others paralysis occurred without any antecedent rigidity. In two cases the paralysis was facial and produced the mask-like expression associated with botulism, in others the paralysis more obviously affected the limbs as in ordinary infantile paralysis. In a few the onset was sudden, but in the majority the symptoms developed gradually but rapidly. Altogether 11 cases in this group have been recognised[2] and 5 died within 5, 6, 8, 11, and 24 days respectively.

In Dr. MacLean's inquiry the majority of the cases occurred among groups of workers in industrial establishments. All these cases were of a mild type, characterised by sudden onset, severe headache, prostration, and rapid recovery, usually within 2–4 days. This group contained 420 persons and the symptoms suggested influenza.

But there were further groups occurring in institutions beyond Glasgow which receive inmates from a working boys' home in Oak-street where 16 cases with symptoms similar to those of the factory-workers occurred. The institutional cases, however, were not all equally mild, and eight deaths are known to have occurred among them.

Nature of Infection: Preventive Measures.

Excluding the influenza element, we would seem to have to deal with a form of affection which attacks the central nervous system, alternately the brain or cord, and falls within the group of affections for which the name Heine-Medin (a combination of the names of two observers of outbreaks last century) has been adopted. Of these the form best known is where the cord is the chief seat of the disease (infantile paralysis or poliomyelitis), of which the outbreak in New York in 1916 is probably the most recent on a large scale. It is possible, as Dr. Picken suggests, that the form simulating "botulism" is an aberrant form of this, chiefly affecting the brain, and indeed in some parts of France where it has been recently present it has been called "lethargic encephalitis" to distinguish it from the more commonly recognised affection of the cord and as possibly due to a separate cause. In any case it would appear to be an affection of the grey matter of the brain as distinct from disease of the corresponding portion of the cord.

The precise methods of spread are somewhat obscure. The occurrence of isolated cases has suggested the agency of insects, and the stable fly has come under suspicion.

With regard to preventive measures, it would seem obvious that the best defence of the population against the spread of the disease lies in a rigid attention to the details of personal and domestic cleanliness, including vigorous action against vermin and insect pests of all sorts. The disease tends to increase during warm weather, and court and stair cleansing and the frequent removal of stable litter should be rigorously enforced.

In order, also, to bring the attendant conditions of each case under review there would be advantage in including both forms of the disease within the Notification Act. Poliomyelitis has been notifiable in England since 1912, but the resolution should include the aberrant brain form known as polio- or lethargic encephalitis.

[1] Report submitted to the Glasgow Committee on Health, June 26th, 1918.

[2] Subsequent information adds to the number.

POLIO-ENCEPHALITIS AND AN EPIDEMIC DISEASE OF OBSCURE ORIGIN.

BY DR. R. M. F. PICKEN.

During recent months cases of a disease which was at first regarded as botulism, a form of food poisoning, but is now generally believed to be polio-encephalitis, an aberrant form of acute anterior poliomyelitis, were reported in various parts of England. The Department was alive to the possibility of the disease appearing in Glasgow, and at least two definite cases fall to be reported.

The First Case.

On Sunday, May 5th, Dr. Picken was asked to see a patient in Ibrox in consultation with a practitioner. This patient, a girl aged 19, first complained on April 18th of dizziness and shivering, associated with stiffness and pain in the arms and legs. She was able to continue at work until April 23rd, when the general symptoms became more severe and the doctor was called in. On April 26th she was confined to bed, and on the 27th sickness and vomiting occurred. Her temperature now became elevated, and on the 29th she was delirious and fell into a semi-comatose condition, in which state she remained at the date of examination.

When examined her appearance was notable, the most striking feature being the complete absence of expression on the face and of ability to move the facial muscles. The eyes were almost closed and apparently incapable of being further opened, and the mouth was hanging open, the muscles of the jaw being paralysed. She moved very little, but was able to respond to questions put to her by her relations. There appeared to be a slight degree of paralysis of the left arm and leg. There was marked constipation. The patient had difficulty in swallowing.

So far the symptoms corresponded generally with those of botulism, but the absence of paralysis of the muscles of the eyeball and an excessive moisture in the mouth in contrast to the dryness of the mouth in botulism indicated that the diagnosis might lie in a different direction. This patient was removed to the Royal Infirmary on May 6th, where she is making a gradual recovery. The symptoms, the gradual onset of the disease and its subsequent course, point to a diagnosis of polio-encephalitis.

The Second Case.

A man, aged 35 years, was admitted to Belvidere Hospital on May 6th as a case of typhus fever, and was reported as such to the committee at the meeting on May 8th. The course of his illness, however, and the post-mortem findings (he died on May 9th) indicate that this also was probably a case of polio-encephalitis. In this instance the onset of illness on May 1st, as reported by Dr. W. Archibald, was more sudden than in the case above reported. It commenced with headache, sickness, stupor, and delirium, the latter appearing early and persisting throughout the illness. In this case also, although it was somewhat difficult to establish, there was evidence of facial paralysis and the expressionless appearance of the face was particularly pronounced. Prior to death there was a definite paralysis of the upper eyelids. In other respects this patient presented features differing from the previous one. Paralysis of the muscles of the eye was present and there was a greater degree of stiffness of the muscles of the body, which in his case was a very marked feature. The skin was hypersensitive.

Post-mortem examination was made by Dr. R. M. Buchanan, who reported evidence of a generalised toxæmia, and in particular a condition of the brain and spinal cord which indicated an inflammatory condition of these organs.

In the former case there was definite history of the consumption of tinned foods, and especially of tinned salmon, but those articles of diet had been shared by the other members of the family, none of whom

took ill. In the second case there was no history of such dietary and there was again an absence of symptoms in the other members of the patient's family.

Other Cases.

In addition to the two cases described in detail, two patients admitted to Ruchill Hospital—one as a case of cerebro-spinal fever, on April 25th, who died on April 27th, and another also admitted as cerebro-spinal fever on May 18th, who died on May 20th—presented cerebral symptoms differing from those of cerebro-spinal fever or any other type of meningitis, and the post-mortem examinations carried out by Dr. Buchanan revealed conditions similar to those described above. These cases had also no association with similar illness in the other members of their families, and conform fairly closely with the descriptions of polio-encephalitis, although the onset of the disease was more than usually sudden.

There is reason to believe, therefore, that cases of this unusual disease have been occurring in Glasgow, and probably many of them have been regarded as suffering from some other more familiar disease, since three of the four cases mentioned came under our notice as the result of mistaken diagnosis.

Dr. Leonard Findlay, of the Royal Hospital for Sick Children, reports the occurrence of six recent cases of disease affecting the nervous system, three of which at least appear to have been typical poliomyelitis, while others agreed more or less closely in symptoms with the cases already described.

OUTBREAK OF AN ACUTE FEBRILE DISEASE IN THREE FACTORIES AND AN INDUSTRIAL SCHOOL IN GLASGOW.

BY DR. A. MACLEAN.

During the first week of May of this year an acute febrile disease with symptoms resembling those of influenza invaded three factories and one industrial home for boys in Glasgow. The three factories accounted for 420 cases, the industrial school for 16. The disease was of a very mild type, and was characterised by sudden onset, severe headache, prostration, occasionally extreme, and rapid recovery usually in 2–4 days. Less frequent symptoms were nausea, shivering, and, very rarely, sore-throat.

No deaths, to our knowledge, occurred, and in no instance do we know of a medical practitioner being consulted.

The significance of this mild outbreak revealed itself when it was brought to our notice that a similar outbreak, attacking some 280 persons, had appeared in two industrial schools, a public school, and a hosiery manufactory in the county of Lanark. The greater number of cases in the county presented the same symptoms as the Glasgow cases, but a few had pulmonary symptoms, and there were 8 deaths —7 from one industrial school and 1 from another. The Glasgow outbreak occurred fully a week before it appeared in the county, and it has been ascertained that a boy resident in the infected industrial home stayed at the Lanarkshire Orphanage from May 10th to 15th, the first case occurring there in the person of the boy who slept in the same dormitory. Further, there is constant communication between this Glasgow home and a Lanarkshire school, where there were 80 cases and 1 death.

Similar outbreaks have occurred at intervals in several industrial schools throughout the country.

In 1888 the late Dr. J. B. Russell made an exhaustive report on an outbreak which occurred in St. Mary's Roman Catholic Industrial School, Glasgow. The Scottish Office caused a report to be published of an outbreak in St. Joseph's Industrial School, Tranent, in 1911. Others have been reported as occurring in various industrial schools in England. This is the first occasion, however, in which factories or works have been invaded by the disease.

Reviewing the published reports of previous epidemics, the Lanarkshire cases, some of which have been seen by us, and the history of the Glasgow cases, it is evident that we are dealing with the same disease, of which the following is a broad description.

Nature of the disease.—It is an acute febrile disease resembling in its mild form influenza, and usually diagnosed as such. When associated in an epidemic with the severe and fatal cases, it is evident that we are dealing with a disease quite distinct from influenza. This is further borne out by the bacteriological findings.

Types and symptoms.—Three types of the disease may be recognised, all sometimes occurring in the same epidemic, but these types frequently merge into one another.

1. *The mild non-pulmonary type (usual type).*—The onset is sudden, headache and prostration being the chief symptoms. There is feverishness, the temperature varying from 99° to 103° F. The recovery is rapid, usually occurring on the second, third, or fourth day. Less frequent symptoms are nausea and vomiting. Sore-throat is a rare complaint.

2. *Malignant type.*—Onset is sudden, coma, varying occasionally with delirium, rapidly supervenes, and death takes place frequently in less than 24 hours.

3. *Pulmonary type.*—The symptoms are similar to those of the first type, but symptoms of pulmonary involvement, with breathlessness and sometimes cyanosis, are superadded. Congestion, œdema, or consolidation of the bases of one or both lungs may occur.

The absence of nervous symptoms—e.g., ptosis, Kernig's sign, strabismus, pupillary irregularity, &c.—is a noteworthy characteristic in this and previous epidemics.

Pathology.—The pathology of the disease has not been completely worked up. Generally speaking, there is congestion of the membranes of the brain, but no meningitis, congestion with œdema, and sometimes consolidation of the bases of the lung, congestion of the mucous membrane of the stomach and upper part of small intestine, enlargement of the solitary glands, Peyer's patches, and mesenteric glands, occasionally enlargement and congestion of the spleen. These post-mortem findings bear a certain resemblance to those of epidemic poliomyelitis, which is of significance, inasmuch as the clinical symptoms are not unlike those occurring in the non-paralytic, a fairly common type of this disease.

Bacteriology.—This has not been completely investigated. Two important points, however, have transpired. The bacillus of influenza is invariably absent. This is in accordance with the clinical picture of the disease. A Gram-negative diplococcus resembling the pneumococcus has frequently been obtained from the nose, throat, lungs, and membranes of the brain.

A CLINICAL STUDY OF CRANIOTABES.

BY EDMUND HUGHES, M.R.C.S. ENG., L.R.C.P. LOND.,
LIEUTENANT, R.A.M.C. (TEMP.).

IF the various modern accounts of craniotabes in infants are analysed and compared they will be found inexact and often discrepant. Further, it has not been possible to derive from them any clear conception of either the time-incidence of craniotabes or the manner of its development and retrogression. Without information of this sort, however, the physician who meets with a case is clinically sightless. He can have no intelligent grasp of the fact when observed, and can make no discriminating use of it. I therefore undertook a fresh inquiry into the subject. The following statements are based largely on a close study of 94 cases, extending over the past four years, and reinforced and controlled by much other material. The work having had to be put aside in an incomplete stage, it has seemed none the less worth while making a brief statement of some of the findings to date, together with certain argument based upon them.[1]

Some Peculiarities of Healthy Immature Skulls.

To avoid confusion with other cranial defects at the same age whose causation may be different,[2] I shall limit the term "craniotabes" to denote the process described in this paper. Certain peculiarities of healthy immature skulls must be understood, or they may be mistaken for craniotabes proper.

Thus, if the skull of a healthy fœtus aged, say, 4½ to 5 months be examined *in situ* while in the fresh state, moderate pressure on the flat cranial bones will be found to produce deformation along their borders. The depression thus caused is shallow, roughly parallel with the edge of the bone, having relatively smooth margins which merge insensibly into the more ossified parts. If the parietal be next removed and examined, it is found firmly ossified, except for a broad even margin all round. This margin, though already tough, is flexible, forming when bent a smooth curvation without "buckling." By the twenty-eighth to thirtieth week this margin has normally become inflexible, in the sense that moderate pressure upon it is insufficient to cause yielding, but results merely in a tilting inward of the whole bone. By full term, *a fortiori*, all such attempts at indentation are unsuccessful.

The only exceptions to this appear to be as follows. In a majority of infants born at term, and for a varying number of weeks afterwards, a slight yielding occurs on *firm* pressure on the tip of the postero-lateral angle of the parietal, usually also on the closely adjacent portion of the occipital; and at the site of the parietal foramina (i.e., from ¾–1¼ inches in front of the posterior fontanelle). A sagittal foramen may, of course, replace these foramina, and exists, according to Broca's figures, in about 1 in 4 skulls. When the sagittal foramen is large, it is associated with widening of the interparietal gap posteriorly and of the posterior fontanelle.

[1] A well-informed summary of the knowledge existing on the subject when the present inquiry was begun will be found in the text-book of Garrod, Batten, and Thursfield, 1913, Art. "Craniotabes."

[2] A curious case recorded by Ballantyne (Ante-natal Pathology, 1902, p. 337) reads like a greatly exaggerated instance of the fœtal form of craniotabes, with delayed re-ossification.

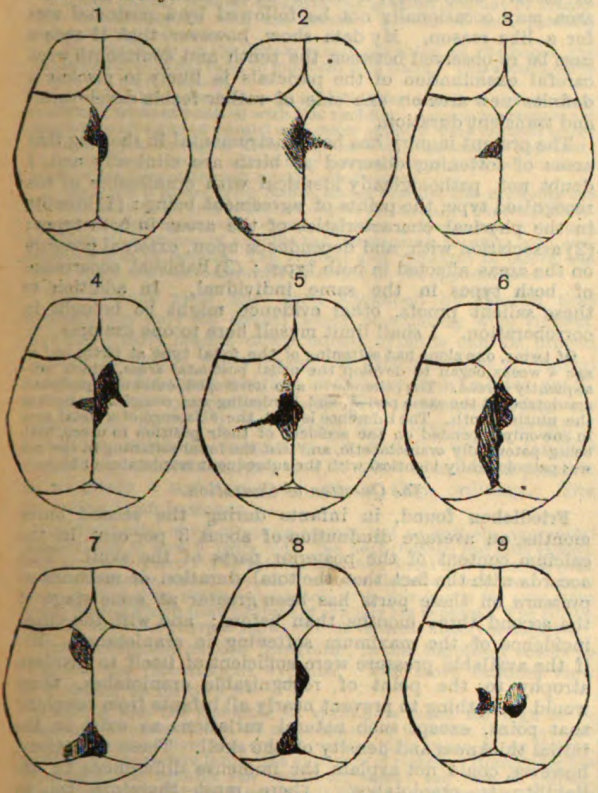
Out of a large number of skulls examined at viable ages, I have found but few which showed a remnant of the even marginal flexibility of the early fœtal bone. If present at all, it is limited to the extreme edges of the bones formed in membrane, and requires decidedly firm pressure to bring out.

The above normal sites of exception to the otherwise general firmness of these bones are readily distinguishable by their situation, their symmetry, and the degree of pressure required to disclose them.

Fœtal Craniotabes.

FIG. I.

The situations shown in Figs. I. and II. are approximate, not to scale, and transcribed from graphic records carefully made at time of observation. The amount of shading expresses relative degrees of loss of elasticity.



Among the population on which my observations have been made, an indefinite though probably no small number of infants born at or near term show true craniotabes at birth. Thus in 153 consecutive births I found craniotabes in 30, or about 1 in 5. This, which may be called "fœtal or primary" craniotabes, has the following characters and conditions: (1) it is asymmetrical, and elicited with slight to moderate pressure; (2) it is found only in vertex presentations; (3) it occurs nearly always in close relation with the sagittal suture[3]; (4) it is habitually followed, after a varying time, by craniotabes of the type recognised and described as such.

The situation of these areas of true fœtal craniotabes is best realised by means of illustrations. In Fig. I. are shown nine different representative sites, selected from observed instances. The amount of softening in craniotabes is conveniently expressed in terms of 4 degrees, which the palpating finger can distinctly recognise. The first degree implies that moderate (never forcible) pressure is required to elicit it. The third degree is that requiring very light pressure; the second degree being intermediate. These three degrees imply the capacity of the bone to recover its shape. In the fourth degree the bone has lost all resilience, and the area is membranous. In these fœtal cases all four degrees may be found in different examples, and even in different parts of the same individual bone. In respect of amount of elasticity, therefore, fœtal craniotabes strictly agrees with that of later ages.

The same agreement holds good with regard to irregularity and asymmetry. In some the sensation imparted to the finger is identical with that given by areas of later origin which are known to be rather slowly hardening, suggesting that some infants are born with remnants of areas formerly more extensive.[4]

After birth the fœtal area hardens or undergoes modification, according to its site. In many instances these patches, which often commence about 2 cm. behind the anterior fontanelle, lie between this and the region of the sagittal or parietal foramen, and so are no longer subject to pressure. A chance is then afforded of ascertaining the rate of healing of a craniotabetic area when suddenly and completely withdrawn from pressure. This, of course, will partly depend on its degree at birth. The shortest time my observations give for the area to become indistinguishable from the surrounding bone is 15 days. The commonest time was from four to five weeks. Some last considerably longer and are still detectible in the twelfth week. The hardening proceeds progressively and evenly, never in irregular patches.

Postnatal Craniotabes.

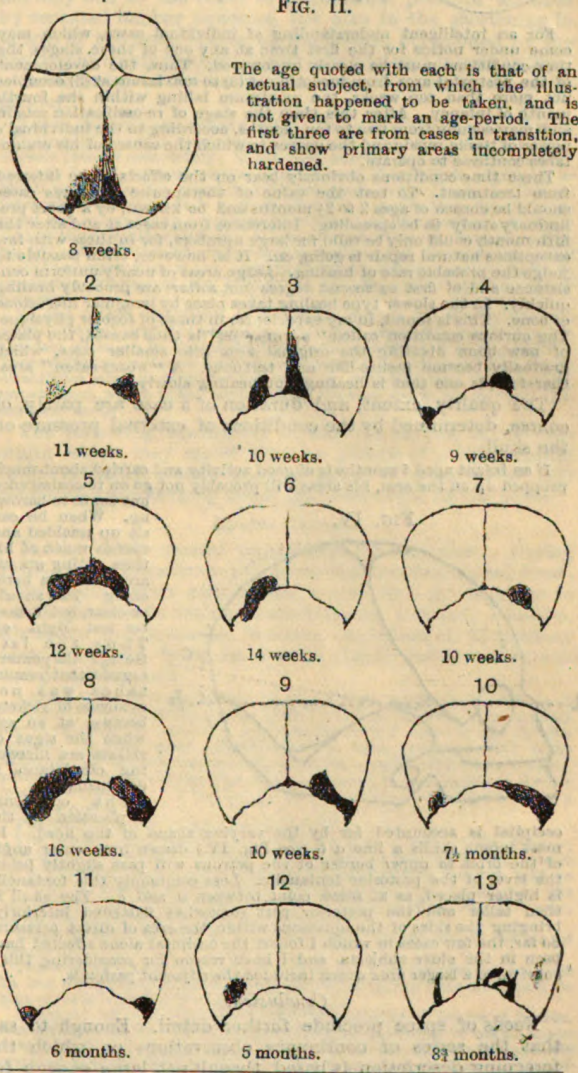
The "postnatal or secondary" area may first become evident towards the end of the first month of extra-uterine life.

It is thus not uncommon for fœtal and postnatal areas to be present on the same skull during the second month. My evidence indicates that the more advanced or extensive the fœtal areas the earlier and more widespread the formation of postnatal areas, and that the milder the former condition the slower and less complete the formation of the latter, though both these rules have exceptions. It will follow that, in the second case, there will be an interval of time during which no craniotabes is present. This circumstance, together with the difficulties of continuously observing some cases, prevents me from formulating the following rule without its qualification. It may, however, be truly posited that *craniotabes, according to its site, may be expected to be followed by, or to have been preceded by, craniotabes in other situations.*

In Fig. II are shown 13 common situations in which postnatal areas may be looked for.

FIG. II.

The age quoted with each is that of an actual subject, from which the illustration happened to be taken, and is not given to mark an age-period. The first three are from cases in transition, and show primary areas incompletely hardened.

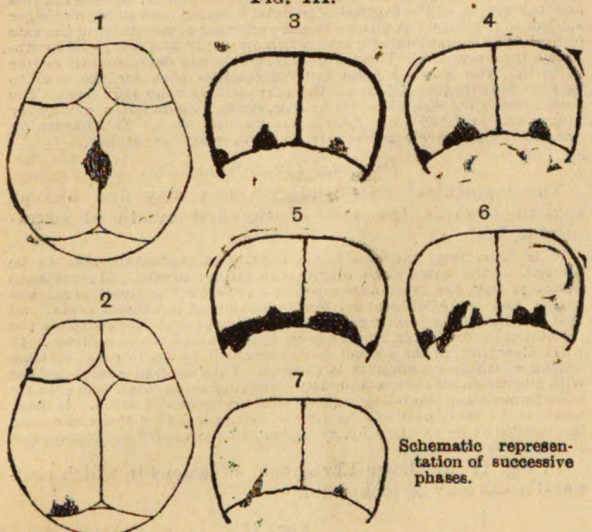


[3] Rarely, a marked softening of the postero-lateral angle of one or other parietal will be found along with vertex craniotabes in the new-born. The only case observed by me showing an exceptional site alone was the premature child of a woman who spent her seven months of pregnancy lying on her back or partly on her side through severe chronic arthritis. The child, who presented in the first position, showed a small discrete area on right parietal above midpoint of lambdoid suture. Large postnatal areas developed later on both parietals.

[4] The examination of the new-born for craniotabes should be repeated on the third or fourth day to allow time for œdema of the scalp to pass off. I have known this to mask smaller areas of softening.

Fig. III. is intended to show in schematic form the typical complete series of events in chronological order.

FIG. III.



Schematic representation of successive phases.

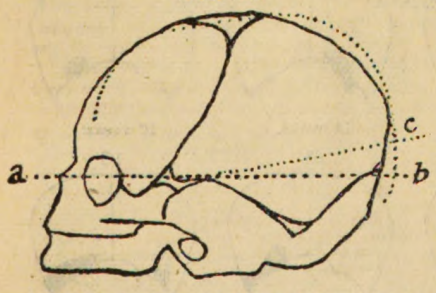
For an intelligent understanding of individual cases, which may come under notice for the first time at any one of these stages, the time-conditions must be clearly understood. Thus, the development of the postnatal area from inception at (2) to maximum at (5) occupies not more than ten weeks, the maximum falling within the fourth month of infancy. After this time the stage of re-ossification sets in and may occupy from two to ten months, according to the individual's power of tissue-repair and the degree to which the causes of his craniotabes continue to operate.

These time-conditions obviously bear on the effects to be inferred from treatment. To test the value of therapeutic measures cases should be chosen of ages 2 to 2½ months and be known, by a short preliminary study to be spreading. Inferences from cases at and after the fifth month could only be valid for large numbers, for in these with few exceptions natural repair is going on. It is, however, often possible to judge the probable rate of healing. Large areas of nearly uniform consistence and of first or second degree (not softer) are probably healing quickly. In the slower type healing takes place by irregular intrusions of bone. This is found, in my experience, in those of feebler physique. The curious condition called "worm-eaten" is thus caused, the plates of new bone dividing the original area into smaller ones, which gradually become fissure-like and tortuous. A "worm-eaten" area, therefore, is one that is healing, but healing slowly.

The quality, extent, and duration of a case are partly, of course, determined by the conditions of external pressure on the skull.

If an infant aged 4 months is of good activity and carried about much propped up on the arm, his areas will probably not go on to coalescence but begin to harden up. When he can sit up unaided and spends much of his time sitting up, his areas take on hardening. This should be clear, but it may be lost sight of. Thus the late George Carpenter[5] argued that craniotabes was not evidence of rickets, because at an age when the signs of rickets are increasing craniotabes is decreasing.

FIG. IV.



The occasional implication of the occipital is accounted for by the varying shape of the head. In most infant skulls a line *a b* (see Fig. IV.) drawn from outer angle of the orbit to upper border of the petrous will pass slightly below the level of the posterior fontanelle. Less commonly this fontanelle is higher placed, as at some point between *b* and *c*. The skull is then taller and the posterior part somewhat flattened inferiorly, bringing the sides of the squamous within the area of direct pressure. So far, the few cases in which I found the occipital alone affected have been in the older subjects, and I have reason for considering this a survival of a larger area which included the adjacent parietals.

Conclusions.

Needs of space preclude further detail. Enough to say that the series of continuous observations on which the foregoing description is based, though not large enough for exhaustive inferences, has been amply sufficient to establish a rule that when an infant is born with craniotabes he will continue to develop it anew in the situations described, and to show that the severities of primary and secondary areas are commonly in direct ratio.

On the other hand, parallel observations on slightly over 100 controls enable me to infer that infants (vertex presenting) born without craniotabes seldom show it postnatally. I have met with six exceptions among these. In all six the postnatal area was single, small, and of the first degree. One may hazard either that a small fœtal area had hardened by the time of birth, or, more rationally, that the combined causes of craniotabes were operating too feebly to produce it in utero. Conversely, it seems likely that a trivial fœtal area may occasionally not be followed by a postnatal area for a like reason. My data show, however, that if such a case be re-observed between the tenth and fourteenth week careful examination of the parietals is likely to disclose a definite new area on one side of rather feeble development and transient duration.

The present inquiry has been instrumental in showing that areas of softening observed at birth are clinically and, I doubt not, pathologically identical with craniotabes of the recognised type, the points of agreement being: (1) identity in the physical characteristics of the areas in both types; (2) association with, and dependence upon, external pressure on the areas affected in both types; (3) habitual occurrence of both types in the same individual. In addition to these salient proofs, other evidence might be brought in corroboration. I shall limit myself here to one example.

Of twins, one alone had softening of the fœtal type at birth, and at age 4 weeks began to develop the usual postnatal areas, which subsequently spread. The other twin also developed extensive postnatal craniotabes at the same period, and hardening was complete in both at the ninth month. The inference is that the existence of a fœtal area in one only depended on the accident of their position in utero, both being potentially craniotabetic, and that the fœtal softening in the one was pathologically identical with the subsequent craniotabes of both.

The Question of Causation.

Friedleben found, in infants during the second three months, an average diminution of about 3 per cent. in the calcium content of the posterior parts of the skull. This accords with the fact that the total duration of mechanical pressure on these parts has been greater at some stage of the second three months than before; and with the time-incidence of the maximum softening in craniotabes. But if the available pressure were sufficient of itself to produce atrophy to the point of recognisable craniotabes, there would be nothing to prevent nearly all infants from reaching that point, except such natural variations as exist in the initial thickness and density of the skull. These variations, however, could not explain the immense differences in the liability to craniotabes. There must therefore be an additional cause; and that this is pathological is shown by the affection being confined to a minority, who moreover are found to give evidence, sooner or later, of disease.

To account for this (organic) part of the causation, at least five hypotheses have been brought forward—i.e., that craniotabes is due to (1) rickets; (2) syphilis; (3) rickets combined with syphilis; (4) one or the other in different instances; (5) neither, but to some cause at present unrealised. Of these, the view numbered (4) is more easily disposed of than the others.

Concerning the forms of craniotabes under discussion, I have not, in over a decade of study of them, met with a case which departed so definitely from type as to fall outside the description already given. Upholders of the above view have the option of showing that this craniotabes consists of two distinct varieties wrongly classified under the same term, or else of falling into an error of theory very prevalent in medical reasoning by which it is carelessly assumed that the same event may have two or more different sets of causes.

The view numbered (5) rests on the undoubted fact that neither syphilis nor rickets can be demonstrated in every case; further, that both are sufficiently common among the town-bred to be regarded as adventitious accompaniments. These points are not easily met.

The absolute frequency of syphilis and rickets in the non-craniotabetic has never, to my knowledge, been worked out; nor have enough cases of craniotabes been followed up to show that they did or did not develop rickets or a syphilis previously latent. The absence of rickets is, one suspects, apt to be loosely affirmed, as it is a troublesome matter to follow up a considerable body of cases through the ages required for certainty on this point. Of 37 in which these conditions were observed I found obvious rickets in 35, in most of these moderately severe. There was also a significant ratio between the amount of craniotabes and the subsequent rickets. Of the two negatives, in one the areas of softening, primary and secondary, were trivial in extent and degree. In the other case the two previous children of that parentage had both been under my observation with rickets of some severity.

Regarding causation by syphilis: of the present 94, 40 were certainly syphilitic, 21 more were probables. In

[5] Carpenter: Brit. Jnl. Chil. Dis., March, 1908.

the remaining 33, evidence was either vague or absent.[6] Only 13 showed a severe infection. For this reason, clinical estimates of its proportion are apt to be fallacious unless examination is made in the early weeks, on repeated occasions, and knowledge is included of the parents or their previous children. On the hypothesis that syphilis is causal, however, these clinical deductions should prove correct:

1. In those severely tabetic, there should be evidence of syphilis, especially of cranial syphilis, co-existing or sequent. Of the present series, 38 had extensive softening, both sides being affected, with confluence of areas. Of these 6 showed severe syphilis, 13 mild forms, and in 19 syphilis was absent on all counts.

2. Where cranial syphilis co-exists, the greatest amount of craniotabes should coincide with the greatest activity of the syphilitic process in that instance.

3. On subsidence of the inflammatory condition of the bones, the craniotabes should be found to diminish *pari passu*. This should occur at least to a partial extent.

Craniotabes, however, in cranial syphilis I find to follow the pressure conditions, without relation with the syphilis. Among my records are cases where all signs of cranial and other syphilis were reduced under treatment; yet during or after their removal, craniotabes appeared. In a number of others, an existing postnatal area behaved during a course of mercury as though totally uninfluenced.

A boy, aged 9 weeks, with rather severe syphilis also involving the cranium, showed an area of second degree (postnatal). Vigorous treatment by inunctions was then carried out for four weeks, before the end of which all evidence of syphilis had disappeared, together with considerable gain in weight. The original area remained as before, and one of larger size had meanwhile developed on the opposite bone.

The curious view has been advanced by Marfan that syphilis can only be causal when co-existing with rickets. But this clearly breaks down unless syphilis can be proved present in nearly every case. It happens that a clinical diagnosis is far more weighty in infancy than in later years, as nearly all congenital cases give evidence within six months of birth. I can assert the absence of syphilis, therefore, without misgiving in certain whole families furnishing craniotabetics; and in a few it has been possible to maintain a scrutiny much closer than ordinary. The following is an instance:—

The first (male) child of young parents had an entirely uneventful infancy, and is now 8 years old. The next (female) had mild rickets, and is now 4 years. The third (male) had fœtal and extensive postnatal craniotabes, and is now, at 12 months, definitely rachitic. I have been in very close professional touch with this family for over eight years, during which time no trace of syphilis has appeared. The father, aged 29, shows no physical signs, and his venereal history is negative.

Such evidence as the foregoing, taken together, seems to rule out the causality of syphilis. The more rational view is, I think, as follows:—

Granting that the incidence of syphilis is much too high to be dismissed as adventitious, we may suppose it to favour the true cause in some manner now obscure. Assuming this cause to be rickets, syphilis will therefore favour the existence of rickets. Hochsinger has concluded that syphilis can hasten its onset; and this, if correct, would help to explain why pressure is likely to produce craniotabes in a syphilitic subject. But one is driven to grant that rickets not seldom exists during the period when the fœtal head comes to assume a more or less constant position in the lower uterine segment.

The following case may be cited as relevant to the present argument.

The first child (female) of apparently healthy young parents had fœtal, and at the second month postnatal, craniotabes, which underwent partial development. No syphilis, but well-marked rickets appeared in second year. During the first pregnancy the father joined the Army, and on a return on leave the mother conceived again. The next child (male), born 13½ months after the first, had fœtal followed by large postnatal areas, and at four weeks an extensive macular syphilide, rhinitis, slight hydrocephalus, &c. He responded well to treatment, though the craniotabes continued to spread, as in others. The fœtal area in the first child was moderate in size, involving the left parietal; in the second larger, involving both bones; and his postnatal areas were also larger.

This is offered as a possible illustration of syphilis in the rôle of accomplice. That the first child is a latent syphilitic is conceivable, but is not an impartial reading of the data.

In imagining a method by which syphilis might favour the cause, the added effect of plus intracranial tension seemed to merit inquiry. Gauging its degree by the fontanelles and amount of venous turgidity, I recorded 41 cases of cranial syphilis during the first four months, finding craniotabes in 9. In 16 the tension was relatively high, and 5 of these had craniotabes. Probably the effect of tension is negligible, as in many it cannot be shown to be increased.

While it is clear that mercury is without influence on craniotabes, the therapeutic test for rickets cannot easily be made on young infants, both through the dietetic limitations and the lack of a "specific" for this disease. Experiments, however, both dietetic and medicinal, had been begun on selected cases, which have had to be temporarily relinquished.

[6] Of 100 cases collected by Lees and Barlow (Trans. Path. Society, 1881) 47 were certainties, 40 more were probables.

THE NERVOUS SEQUELÆ OF CEREBRO-SPINAL FEVER.

BY CECIL WORSTER-DROUGHT, M.B. CANTAB., &C.,
TEMPORARY CAPTAIN, R.A.M.C.; NEUROLOGIST AND OFFICER IN CHARGE, CEREBRO-SPINAL FEVER WARD, ROYAL HERBERT HOSPITAL.

PRIOR to the introduction of repeated lumbar puncture and the intrathecal administration of specific anti-serum as routine measures in the treatment of cerebro-spinal fever many of the relatively few cases that recovered appear to have suffered from some permanent disability, either mental or physical.

The older writings on the subject abound with references to the frequency of infirmities met with in survivors from the disease. Some allowance, however, must be made for the fact that, owing to the absence of accurate diagnosis by an examination of the cerebro-spinal fluid obtained on lumbar puncture, polio-encephalitis and the so-called meningeal form of acute anterior poliomyelitis were often confused with meningitis; consequently many of the paralytic sequelæ of the former diseases were erroneously attributed to meningitis. Nevertheless, serious disabilities frequently followed cerebro-spinal fever, by reason, no doubt, of the compression to which the brain structures were subjected during the course of the disease by the increased tension of cerebro-spinal fluid unrelieved by lumbar puncture.

Contrary to popular supposition, it is an undoubted fact that in recent years serious sequelæ have been considerably less frequent than formerly. These improved results are not only due to the relief of intracranial pressure afforded by repeated lumbar puncture, but also to the shortening in length of the usual course of the disease occasioned by the use of antimeningococcal serum administered intrathecally.

In infants, as formerly, the sequelæ remain the most serious.

Batten, for instance, writing in 1915, states that in the endemic form affecting infants and occurring annually in London, only 15 per cent. of cases recover completely; 35 per cent. survive but exhibit some permanent defect—either mental impairment, hemiplegia, diplegia, or blindness, while the remaining 50 per cent. prove fatal. In infants internal hydrocephalus is a most frequent complication, its development and course being considerably modified by the anatomical condition of the infantile cranium; the intracranial pressure brought about by the accumulation of cerebro-spinal fluid in the ventricles not only leads to compression of the cerebral tissues, but also expends itself in producing bulging of the fontanelles and separation of the cranial sutures.

In the infant, therefore, the nervous structures of the cerebral cortex are subjected to a considerably more gradual pressure than is the case when, as in the adult, the cranial capacity is a fixed quantity. These facts may account for the occurrence in children of permanent disabilities such as diplegia, blindness of central origin, and mental impairment, which at the present time are observed in adults only with extreme rarity.

The following description of the conditions of nervous origin which may result from an attack of cerebro-spinal fever is based chiefly upon a study of a series of 120 recovered cases coming under the observation of the writer.

Mental Changes.

In the adult mental impairment is very rare. During 1915–17, of 120 patients recovered from cerebro-spinal fever, mainly adolescents and adults, I met with no instance in which permanent mental enfeeblement resulted. Bourke, Abraham, and Rowlands, however, state that of 77 military cases recovered from the disease (1915) feeblemindedness was present in two.

Among the minor psychical changes Netter mentions conditions of irritability and puerility, while other French authors describe marked loss of attention or memory, moroseness, morbid shyness and morbid egoism. During early convalescence I have observed that some patients may exhibit unevenness of temper, anger being easily evoked, while inability to concentrate the attention for any length of time is relatively frequent. Such changes rarely persist, but disappear after a variable period.

Puerility occurred in one case out of 120.

The patient, aged 23, had survived a severe attack of the disease; duration approximately 40 days. When first beginning to walk about he would attempt to carry out practically anything he was told to perform, no matter how absurd it might appear—e.g., walking on his hands and knees, lying under bed, &c. After a week or two, however, he recovered his normal mental equilibrium.

Three patients of the 120 recovered cases complained of defects of memory.

The first, seen three months after discharge from hospital, stated that he had occasional difficulty in remembering things that were told to him or orders it was his duty to carry out.

A second patient, four weeks after termination of course of illness, complained that he had forgotten the names of several of his intimate friends and also of places he had visited. When seen a year later his memory had greatly improved, but he considered that he could not remember facts as well as prior to his illness.

The third patient was employed in clerical duty at a military depôt; on returning to work he found that he had great difficulty in adding up columns of figures that previously he had managed with ease; no other psychical symptoms were complained of. Six months later his defect was still present.

Foster and Gaskell mention one recovered case in which there was complete loss of memory. As a concomitant paralysis of the right arm was present, however, the amnesia possibly owed its origin to a definite and localised cortical lesion. Six months later this patient's memory was almost completely restored, although some weakness of the arm persisted.

As regards permanent mental defects following the disease in infants, Looft estimated that 3·7 per cent. of 539 idiots owed their condition to an attack of meningitis. Netter, without doubt rightly, attributes a considerable number of such cases to insufficient serotherapy. Cases in which dementia results are often suffering from chronic hydrocephalus, which in some instances may persist for a considerable period. In all cases with dementia care should be taken to exclude hydrocephalus, even though apparent recovery from meningitis has occurred, before the patient leaves hospital.

Sensory Symptoms.

Headache.—Patients may continue to complain of headache for some time after convalescence is established and Kernig's sign is definitely absent.

In the majority of cases the headache entirely disappears after a few months; in others, however, it persists for longer. Of the 120 recovered cases already mentioned only 8 continued to suffer from headache three months after becoming convalescent; a few stated that the symptom only occurred after exertion, and in one case it was merely nocturnal.

Persistent headache of a severe nature may be due to a certain degree of hydrocephalus, which later may give rise to serious symptoms and even produce a fatal result.

Pain in the back.—Pain, weakness, and stiffness in the back are almost invariable complaints during the early stages of convalescence; in consequence, an awkward gait may persist for some weeks.

The majority of patients cease to experience backache about 3–4 months after termination of course of illness. Several, however, may complain of weakness in the back for many months after recovery; in some the symptom is only noticed on stooping, while in others pain is present in damp weather. Hyperæsthesia of the spine may occasionally persist well into convalescence.

That the pain and weakness in the back are due to the effect of the disease itself rather than to that of lumbar puncture is shown by an observation by Foster and Gaskell. A certain case in which lumbar puncture was performed once only, owing to the presence of auricular fibrillation, recovered completely from meningitis after a course of about 40 days; the patient, however, exhibited the symptom of pain in the back to a greater degree than other cases on whom a dozen or more punctures had been performed.

Also, I have known cases recovering from an abortive attack of the disease who had had no more than one or two punctures complain of pain and weakness in the back for a longer period than patients who had passed through a severe illness, necessitating the performance of many lumbar punctures. In all recovered cases I have carried out an examination for possible lesions of the cauda equina resulting from the punctures; of upwards of 120 cases, however, in no single instance could the slightest lesion be demonstrated.

Pain in the limbs.—Pain in the legs, persisting for more than three months after recovery, is a comparatively rare sequel. Occasional pain was complained of in two only of the 120 cases, the leading question not being put. Only one patient volunteered the information that he experienced occasional pain in the arms.

Motor Defects.

Ocular muscles.—As lesions of the nerves supplying the muscles of the eyeball usually improve coincidently with recovery from meningitis, permanent strabismus as a sequel is most uncommon. When present it is usually the result of involvement of the sixth cranial nerve.

Of the 120 cases only 2 exhibited an ocular palsy persisting for longer than three months after recovery from the disease.

The first patient, who during the attack of cerebro-spinal fever had had complete paralysis of both external rectus muscles, exhibited when seen three months after his discharge from hospital, complete paralysis of the left external rectus, while some weakness still remained in that on the right.

The second patient, examined six months after recovery, showed some nystagmus and marked weakness of one external rectus muscle.

Bourke, Abraham, and Rowlands, of 77 cases recovering, met two with permanent strabismus.

As a rule, the pupils remain somewhat dilated for some weeks after establishment of convalescence, but eventually become normal. Persistent myosis or inequality in the size of the two pupils is extremely rare. Permanent nystagmus also is most infrequent.

Limb palsies.—Paralysis of limbs, developing during the course of the disease, may persist for several months after recovery from meningitis. Monoplegias due to the involvement of spinal nerve roots almost always disappear eventually, although a considerable time may elapse before function is fully restored. As an example the following case may be mentioned:—

A child aged 6 years, suffering from cerebro-spinal fever, exhibited on the sixth day of illness considerable weakness of both arms. Three days later patient was unable to abduct either arm at the shoulder, the deltoid muscles being paralysed and flabby; paralysis of right biceps and triceps was also present, no degree of active flexion or extension being possible at the elbow. The supinator, biceps, and triceps jerks were unobtainable in both limbs, and hyperæsthesia was particularly marked in the right. By the fourteenth day there was a fair amount of wasting of affected muscles in right arm. Meningococci were present in cerebro-spinal fluid until ninth day of disease, and recovery from meningitis, as shown by the evacuation of a clear and sterile cerebro-spinal fluid, was not complete until the thirtieth day.

Fourteen days after recovery movement in the left arm had returned, but the right still showed paresis of the deltoid, biceps, and triceps. No response to faradism was obtained in these muscles, and with galvanism A.C.C. was greater than K.C.C. in the deltoid; in the biceps and triceps A.C.C. was about equal to K.C.C.

Full power was recovered in the affected arm about seven months after recovery from meningitis.

If a monoplegia or paralysis of a group of muscles persists without improvement, it is probably dependent upon definite changes in the anterior cornual cells.

Hemiplegia, occurring as a complication of cerebro-spinal fever, usually terminates in almost, if not quite, complete recovery.

For instance: In one case of the series, a boy aged 15 who ran a recrudescent course of over 80 days, hemiplegia developed about the fifty-first day of illness. By the termination of the course of meningitis (eightieth day), and about 30 days after appearance of hemiplegia, the paralysis of the arm had quite disappeared. Seven and a half months later, all that remained of the lower limb palsy was weakness of calf muscles and inability to flex or extend great toe; the other toes exhibited weak movement. Both patellar clonus and ankle clonus, previously present, had disappeared, but on the affected side, the knee-jerk and tendo Achillis jerk remained brisker than those in the opposite limb, and the plantar reflex was still extensor.

Cerebral hæmorrhage, occurring during the course of cerebro-spinal fever in middle-aged patients with pre-existing nephritis, may lead, if the patient recovers, to permanent hemiplegia.

Flaccid paraplegia, fortunately a very rare complication, may show some improvement but is usually permanent.

Some degree of weakness in the legs and unsteadiness of gait is frequent during the early stages of convalescence.

In a few instances, according to Sophian, exaggerated knee-jerks associated with a true ankle clonus and extensor plantar reflexes, may be elicited. I have frequently observed ataxia with a positive Romberg's sign and difficulty in walking; in many cases, exaggeration of the deep reflexes is also present. In no instance, however, in the absence of a definite upper neurone lesion has one found ataxia associated with either definite ankle clonus or a true extensor plantar reflex. Romberg's sign was not observed in any case in which a period of one month had elapsed from the time of the patient's beginning to walk.

One man, aged 30, was met with, who had had an attack of cerebro-spinal fever at Belfast eight years previously; for a considerable period following his recovery he had complained of weakness affecting the legs. When examined he stated that he still felt weak and "shaky" in the legs after violent exertion; he exhibited, however, no abnormal physical signs.

Peripheral neuritis.—This condition is a very rare complication of cerebro-spinal fever.

Of two cases seen in which definite neuritis affected the lower extremities, complete reaction to degeneration in the muscles supplied by the affected nerves developed in neither case. In one case the tendon reflexes were beginning to return, and sensation was nearly normal within three months of recovery from meningitis; the second patient, after a similar period, exhibited normal cutaneous sensation, but both the knee and ankle-jerks were still absent, and the vibration sense remained much diminished.

Muscular rigidity.—Rigidity of the cervical muscles persisting for any considerable period after recovery is extremely rare.

As a rule, neck rigidity is absent before or within a week or so of the cerebro-spinal fluid returning to normal. In the following case, however, actual head retraction persisted long after the course of meningitis, and even when the patient was up and about.

A youth, aged 19, was admitted to hospital acutely ill on the second day of a recrudescent attack of cerebro-spinal fever; four days earlier he had had an abortive attack elsewhere. On admission considerable head retraction was present. This symptom was still as marked on the twenty-fourth day of illness, by which time the cerebro-spinal fluid obtained on lumbar puncture was quite clear, sterile, and contained no more than the normal number of cells. At times occipital retraction had been so extreme as to cause difficulty in swallowing.

One month after the termination of the course, the patient having been up and about for over a week, there was still a tendency to head retraction, with inability to bring the head quite into the vertical position. Massage, &c., was then instituted and four weeks later there was some improvement; he remained, however, unable to flex the head beyond the perpendicular while standing in the erect position. Finally, it was not until three and a half further months had elapsed (five and a half months from termination of course of meningitis) that the patient was able to flex the head sufficiently for the chin to reach the chest.

Kernig's sign, in the majority of cases, persists for the first 5–14 days of convalescence.

In a few cases the sign may still be present for 20 or even 30 days following the evacuation of normal cerebro-spinal fluid and in the absence of all symptoms of hydrocephalus. Some rigidity of the hamstring muscles can occasionally be demonstrated 2–3 months after recovery.

Other Nervous Conditions.

Aphasia.—Persistent aphasia has been noted in rare instances. The only case of our series in which this complication occurred had fully recovered the faculty of speech before the termination of the course of the disease.

Epilepsy.—Sainton mentions epilepsy as a rare but occasional sequel of recovery from cerebro-spinal fever.

This observer mentions one case in which the crisis began with an aura of gastric origin—nausea and vomiting, followed by loss of consciousness and epileptic convulsions. The cerebro-spinal fluid between the crises was normal, but the fluid obtained immediately after the seizure showed a slight lymphocytosis. The general condition of the patient was good. Voisan reports a somewhat similar case.

Petit mal is also stated occasionally to occur.

Neurasthenia.—Considering the severity of the usual course of the disease process in cerebro-spinal fever, I have found the occurrence of true neurasthenia following recovery from the disease surprisingly uncommon.

It is contended by Dejerine and others that to constitute true neurasthenia, in addition to a state of neural fatigue, there must exist a condition of continued emotivity; the non-adaptation of a continuous emotive cause, to which is often added an obsessing preoccupation, produces a condition of neural exhaustion, and the sum-total of the phenomena resulting justifies a diagnosis of true neurasthenia.

The appearance of neurasthenia following recovery from cerebro-spinal fever, therefore, would depend to a large extent upon the temperament and inherent or acquired tendency to emotivity of the individual, as well as upon the severity of the disease. Chronic cases, it may be remarked, are more liable to become neurasthenic than those exhibiting a shorter course. Six patients only of the 120 cases recovered could definitely be said to show signs of true neurasthenia when examined 4–6 months after recovery from meningitis; of these six patients, two at least were neurasthenic prior to the attack of cerebro-spinal fever. Of the remainder the following case serves as an example.

The patient was examined six months after recovery from a severe attack of cerebro-spinal fever lasting approximately five weeks. He complained of frequent headache, soreness in the limbs, and of fatigue upon the slightest exertion; his appetite was poor and he slept badly.

Physical signs: The patient was thin and perspired freely during the examination although it was winter. The pupils were somewhat dilated, equal, and reacted sluggishly to light and accommodation. There was a well-marked tremor of the outstretched hands; the superficial reflexes were brisk and the knee- and ankle-jerks exaggerated. No ankle clonus was elicited and both plantar reflexes were flexor.

Two other patients exhibited a somewhat similar condition; one, in addition, complained of occasional loss of memory. Another recovered case, seen four months after his discharge from hospital, complained of sleeplessness but showed no other evidence of neurasthenia.

A slight tremor of the outstretched hands is frequently observed during the first few months following recovery from the disease.

One patient examined five months after recovery from meningitis closely simulated a case of disseminated sclerosis.

The man, aged 26, complained of occasional inability to use the left hand and also of frequent diplopia. On examination there was distinct rotatory nystagmus on lateral deviation of the eyes, together with weakness of the left external rectus muscle. The pupils were somewhat dilated but reacted normally to light and accommodation; the optic discs showed nothing abnormal. There was a coarse tremor of the outstretched hands, more marked on intention, together with some incoördination of the left arm. The left hand-grip was considerably weaker than that on the right; the left supinator, biceps and triceps jerks were brisker and of greater range than those on the opposite side. Both the knee and tendo Achillis jerks were brisk and exaggerated but equal on the two sides; ankle clonus, however, was absent and both plantar reflexes were definitely flexor. The abdominal and epigastric reflexes were also well marked and speech was normal.

The presence of the abdominal reflexes and a bilateral flexor plantar response alone serve to distinguish the above condition from disseminated sclerosis.

Foster and Gaskell mention a recovered case exhibiting exaggerated knee-jerks, volitional tremors, weakness of the bladder, and pallor of the optic discs.

Special Senses.

The eye.—Blindness may result from (1) damage to the tructures of the eyeball; (2) permanent changes in the nervous tissues associated with vision.

1. *Damage to structures of eyeball.*—Corneal ulceration may leave permanent opacities, and loss of vision is the usual sequel to iridocyclitis. This latter complication had occurred in one case of the 120; when examined three months after recovery from meningitis he was able only to distinguish light from darkness with the affected eye. Panophthalmitis is almost invariably followed by complete blindness in the affected eye.

A large vitreous hæmorrhage, associated with optic neuritis, occurred in one of our cases during the course of illness. When seen three months after recovery, the vitreous was practically clear and vision in the affected eye was 6/9.

2. *Permanent changes in the nervous structures.*—In adults, blindness of central origin is very rare; when present, it is usually due to optic atrophy and is permanent and incurable.

In infants suffering from the posterior basic type of the disease, blindness, according to Langmead, develops in about 30 per cent. of cases. Although at first the optic discs may exhibit no definite change, optic atrophy usually develops at a later stage. In most instances the blindness is due to changes in the visual centres situated in the cerebral cortex of the occipital region.

No instance of blindness of nervous origin occurred in the series of cases under review.

The ear.—Deafness is the most common of the serious sequelæ met with at the present day.

The disability is almost always bilateral and if persisting during convalescence, is usually permanent; some recovery, however, has been known to occur in a few instances after an interval of two or three months.

Below the age of 7 or 8 years permanent deafness usually leads to an associated mutism; even though speech has begun it gradually disappears. Statistics of the proportion of acquired deaf-mutes who owe their defect to cerebro-spinal meningitis are widely divergent, the number as estimated by different observers varying from 8 to 45 per cent. The condition appears less common in the posterior basic type of the disease than in the more ordinary types. There is little doubt, however, that permanent deafness resulting from cerebro-spinal fever is much less frequent now than formerly. The condition is probably brought about by atrophy of the auditory nerve and possibly some destruction of the cochlea.

Permanent and absolute deafness was present in 2 cases only of the 120 recovered from cerebro-spinal fever. Partial deafness (20 per cent.) of central origin resulted in one other case.

Vaso-motor and Secretory Disturbances.

In the majority of cases a well-marked tache cérébrale can usually be elicited for many weeks, or even months, following the disease.

Profuse and easily elicited perspiration, apart from a condition of neurasthenia, was present in some cases of the series up till two or three months after recovery from meningitis.

The Reflexes in Recovered Cases.

The following observations are the result of a study of 120 cases recovered from the disease and seen at various periods from two months to one year after recovery. One case of hemiplegia is excluded.

Knee-jerks.—In five cases only were the knee-jerks found absent, in spite of the employment of the usual methods of reinforcement.

Of these five cases, in two patients their absence was dependent upon the presence of definite peripheral neuritis, the tendo Achillis jerks also being absent, together with loss of both epicritic and protopathic sensibility over certain areas of the lower limbs. In two other cases the tendo Achillis jerks also were not elicited, although there was no definite evidenc of neuritis. The last case exhibited absent patellar reflexes, but the tendo Achillis jerks were brisk.

In 10 cases the response to tapping the ligamentum patellæ was very slight.

In 30 cases the knee-jerks were distinctly brisk and exaggerated, but in no instance was this condition associated with either true ankle clonus or a definite extensor plantar reflex.

In the remaining 75 cases the knee-jerks could be described as moderate.

Marked inequality in the reflexes of the two sides was noted in three instances only, and was unassociated with any other physical signs.

Tendo Achillis jerks.—This tendon reflex is usually proportional to that obtained at the knee.

In one case only, mentioned above, were the tendo Achillis jerks elicited in the absence of the patellar reflexes. In two instances the tendo Achillis jerks were brisk, but the knee-jerks excessively slight.

Inequality of the ankle-jerks on the respective sides was observed in two cases, one of which also exhibited a corresponding inequality in the knee-jerks.

In no instance was true ankle clonus obtained. Three cases showed what might be described as unilateral pseudo-ankle clonus, unassociated with any signs of an upper neurone lesion.

Plantar reflexes.—In all cases plantar stimulation yielded a flexor response.

Abdominal reflexes.—It would appear that cerebro-spinal fever may occasionally lead to permanent loss of the abdominal reflexes.

Failure to elicit these reflexes occurred in three cases; of these, no patient exhibited any other abnormal physical signs and in each they had been obtained in the earlier stages of the attack of cerebro-spinal fever.

In 14 cases the abdominal reflexes were only very slight, while in eight they were more than usually brisk. In all the remaining cases these superficial reflexes were moderate. Inequality was noticed in two cases only.

Summary.

A summary of the more serious sequelæ occurring in the series of 120 cases is as follows:—

Strabismus	2 cases.	Hemiplegia	1† case.
Blindness (peripheral) (one eye)	1 case.	Neurasthenia (true) ...	4 cases.
Monoplegia	1* ,,	Deafness (absolute)	2 ,,
		,, (partial)	1 case.

* Function fully restored about 7 months after recovery from meningitis.

† Recovery nearly complete as regards motor power 7½ months after onset.

From this table it will be seen that including neurasthenia 10 patients only of the 120 (8·3 per cent.) suffered from more or less permanent sequelæ.

Of the military cases recovering from the disease—94 in number—as far as I am aware it was necessary sooner or later to discharge as medically unfit for further Army service in any category whatever 11 cases only (11·7 per cent.).

Of these, one patient was neurasthenic prior to developing cerebro-spinal fever, and in addition had double otitis media of old standing; in the ordinary course of events he would have been discharged quite apart from the attack of cerebro-spinal fever. In four further cases discharge was also recommended on account of neurasthenia.

The presence of permanent deafness accounts for two others.

One patient each was invalided on account of one of the following disabilities: persistent strabismus, blindness (peripheral) of one eye, residual weakness of the foot remaining after hemiplegia, and lastly, in a patient aged 41, persistent pain in the lumbar region on exertion.

A NEW METHOD OF PREPARING GONOCOCCUS ANTIGEN,

AND A NEW TECHNIQUE FOR THE COMPLEMENT DEVIATION TEST.

BY DAVID THOMSON, M.B., CH.B. EDIN., D.P.H. CAMB.,
CAPTAIN, R.A.M.C.

THIS work was carried out in the laboratory of the Military Hospital, Rochester Row, London, S.W., under the direction of Lieutenant-Colonel L. W. Harrison, D.S.O., R.A.M.C.

Introduction.

The complement deviation test in gonorrhœa is destined to be of great importance. It is well known that it is extremely difficult to determine, by clinical and microscopic methods, when a person is definitely cured of this disease. This is especially true in the case of women, and it is a great responsibility for a physician to state that a given case is free from infection. The test will come to be of great value in this respect. It will prove a great source of help to the gynæcologist and will aid considerably in the differential diagnosis of many obscure cases of joint disease.

Researches which Led to Discovery of the New Method of Preparing the Gonococcus Antigen.

The gonococcus is a germ which autolyses or breaks up very readily. For this reason a vaccine of the organism does not keep well, but rapidly disintegrates and eventually becomes an autolysate. An investigation was carried out with a view to finding the cause of this autolysis, so that a more stable vaccine might be prepared. It was eventually ascertained that weak acids prevented autolysis, but that weak alkalies increased it. In consequence the vaccine is now made up in a weak acid solution by using 0·6 per cent. acid sodium phosphate instead of ordinary saline. In the course of this research it was found that the gonococcus was extremely soluble in alkali, so much so that if a profuse growth of the germ is shaken up with beads in an N/10 or N/20 solution of sodium hydrate, a clear solution is formed almost instantaneously. If sufficient acid be added to this alkaline solution to render it acid, a white precipitate is immediately formed, which is probably a precipitate of fatty acids. So it would appear that the gonococcus consists largely of a fatty substance, which is immediately saponified by the addition of an alkali. The meningococcus is similarly soluble in alkali, but apparently not quite so soluble as the gonococcus, and a faint milky tint is left in the solution. A strain of *Micrococcus catarrhalis*, on the other hand, was not soluble in alkali, so that a permanent opaque white emulsion remained after shaking up a growth of this organism in N/20 sodium hydrate. It would appear that this might be a useful method of distinguishing between these three allied species of organisms.

Method of Preparing the Gonococcus Antigen.

About this time Lieutenant-Colonel Harrison asked me to try to work up the complement deviation test for gonorrhœa. He had used the ordinary gonococcus vaccine as antigen with successful results in 1914. In consequence I employed at first our stock vaccine and found that it gave successful results when used in a strength of about 100 millions per c.cm. More concentrated vaccines were too anticomplementary for use. It then occurred to me that an antigen prepared by dissolving the gonococci in alkali and then rendered neutral might be suitable, and indeed it proved to be superior to the vaccine itself, being less anticomplementary and at the same time more powerful as an antigen in the blood test.

I make up this dissolved antigen in the following manner:—

(1) Prepare a standard emulsion of gonococci, such that 1 c.cm. contains 1000 millions per c.cm., and place this in a sealed test-tube about 1 inch in diameter.

(2) Shake up a profuse growth of gonococci (24 hours' incubation) in a test-tube containing beads and about 6 c.cm. of saline.

(3) Add one-half of this concentrated emulsion to a test-tube (A) of the same diameter as that which contains the standard and add the other half to a similar test-tube (B).

(4) Dilute the emulsion in tube (A) until it exactly matches the standard containing 1000 millions per c.cm.

(5) To the other tube (B) add a few c.cm. of N/10 sodium hydrate to dissolve the gonococci; a clear alkaline solution will be immediately obtained. Now add N/10 hydrochloric gradually until it is just neutral or very faintly alkaline to litmus. We now have a nearly neutral solution of gonococci. Add to this 0·85 per cent. saline containing 0·5 per cent. carbolic acid until the volume is exactly the same as that in tube (A), prepared as in (4) to match the standard. This gives us a solution containing 1000 millions of dissolved gonococci per c.cm. This should be stored in the ice chest as the stock antigen. It appears to keep well, and it does not become septic because of the weak carbolic it contains.

(6) For use this antigen should be diluted 10 times with 0·85 per cent. saline so as to bring it to a strength corresponding to 100 millions per c.cm. When used in the blood test it will be found that this antigen will absorb, as a rule, much less than one minimum hæmolytic dose of complement.

Antigens of many strains of gonococci have been prepared as above and are now being used in this research. So far I have tested the sera of 30 cases with 12 separate antigens, as well as with a mixed antigen composed of all the 12 strains together. This has shown clearly that a compound antigen is better than the antigen prepared from a single strain. A single antigen may only give a very weakly positive test with a given serum, while the single antigen of a different strain will give a strongly positive test; a compound antigen, however, gives a good positive where a single antigen may only give a very indefinite positive. It was also considered advisable to use a meningococcus antigen simultaneously with the gonococcus strains in my experiments, and a culture of this organism was kindly given by Major T. Hine, R.A.M.C. So far my experiments have shown that the meningococcus antigen almost invariably gives a weakly positive result with a strongly positive gonococcal serum; but a weakly positive serum gives a negative result with the meningococcus antigen. This shows that the meningococcus is a very closely allied organism.

Parke, Davis and Co.'s compound gonococcus antigen was tested against a compound gonococcus antigen prepared by the new method described above. The latter proved to be superior in two respects. It was less anticomplementary and more powerful antigenically, and sera which gave a weak positive with Parke, Davis and Co.'s antigen gave a strong positive with that prepared by the new method. It would appear therefore that a definite advance in the preparation of the antigen has been achieved.

The New Technique Employed in Carrying Out the Blood Test.

For this new and highly satisfactory technique I am indebted to Lieutenant-Colonel Harrison. He advised me at the commencement of my experiments to use a well-diluted serum and to allow for thorough fixation of the complement by placing the tubes in the ice-chest overnight previous to the addition of the sensitised cells, according to the method devised by Dr. Griffith, of the Local Government Board Bacteriological Laboratory, as a result of his researches on the Wassermann test (unpublished).

(1) *Inactivation of the serum.*—The serum to be tested is inactivated by heating to 55° C. for ten minutes in a water bath before dilution.

(2) *Standardisation of the complement.*—The complement should be titrated against the stock antigen diluted 1 in 10 with 0·85 per cent. saline as used in the test. To 12 Wassermann tubes add 0·1 c.cm. of guinea-pig serum (complement) diluted as follows:—

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)
1/10	2/10	3/10	4/10	5/10	6/10	7/10	8/10	9/10	1/100	1/110	1/120

To each add 0·1 c.cm. of the diluted antigen (1 in 10) and 0·1 c.cm. of saline. Shake the tubes and place the tray in the ice-chest for one hour. Then put tray in water bath at 37° C. for half an hour. Add to each tube 0·1 c.cm. of fully sensitised sheep's corpuscles (3 per cent. suspension). Replace tray in water bath at 37° C. and take the readings after 15 minutes. The highest dilution of complement which produces complete hæmolysis should be taken as one minimum hæmolytic dose.

(3) *The Test.*—Three tubes, A, B, and C, are employed.

(*a*) To A and B add 0·1 c.cm. (at a dilution of 1 in 20) of the inactivated serum to be tested. To C add 0·1 c.cm. of normal saline.

(*b*) To A add complement 0·1 c.cm. containing 3 min.* hæmolytic doses.
" B " " " " 2 " " "
" C " " " " 2 " " "
* Minimum.

(*c*) To A, B, and C add 0·1 c.cm. compound antigen (diluted 1 in 10). Tube C acts as the control.

(*d*) Place the tubes in the ice-chest overnight and next morning add to each 0·1 c.cm. of a 3 per cent. emulsion of fully sensitised corpuscles. Then place the tubes in the water bath at 37° C. and take the reading after 15 minutes. The control tube C should show complete hæmolysis.

Hæmolysis in A and B indicates a negative reaction. No hæmolysis in A and B indicates a strong positive. No hæmolysis in B alone indicates a weak positive.

N.B.—An antigen control is preferable to a serum control, since the antigen absorbs a considerable amount of complement during the long period of fixation in the ice-chest. It is not practicable to use the long fixation method in the process of standardising the complement, since the complement deteriorates from day to day. As a rule, it is hardly necessary to use a serum control, since the serum is diluted 1 in 20. With a serum, however, which has stood for several days and may be septic an additional serum control would be advisable.

The results obtained have been exceedingly gratifying, and this is due, no doubt, to the superiority of the antigen as well as to the superiority of the long method of complement fixation in the ice-chest. The sera of patients whose gonorrhœal discharge only commenced one week previously have all given a positive test—some weak, some strong.

The test also indicates the presence of the disease long after the disappearance of the gonococci, according to the microscopic and cultural tests. A case which had had no discharge for a month gave a strong positive test, and he relapsed shortly afterwards.

In a series of 20 cases in the hospital 19 gave positive tests and one was negative. The negative case had shown no gonococci microscopically during the previous three months, and was evidently free from the disease. All normal sera so far have given negative results.

I wish to thank Dr. A. Allport for his assistance in supplying me with cases and the histories thereof from his clinic at the hospital. I am especially indebted to Lieutenant-Colonel Harrison for giving me the full credit of this work, since the success obtained has been so largely due to technique which he advised.

A QUICK METHOD OF DIAGNOSING THE TYPE OF MENINGOCOCCUS IN CASES OF CEREBRO-SPINAL FEVER.

BY A. S. GORDON BELL, M.R.C.S., L.R.C.P. LOND.,
TEMPORARY MAJOR, R.A.M.C., OF THE CENTRAL CEREBRO-SPINAL FEVER LABORATORY;
AND
MISS I. M. HARMER,
OF THE CENTRAL CEREBRO-SPINAL FEVER LABORATORY.

IN the effective treatment of cerebro-spinal fever early recognition of the type of the infecting meningococcus is of the utmost importance in order that the corresponding specific curative serum may be given as soon as possible.

Under the most favourable circumstances 48 hours must elapse before the meningococcus can be grown from the cerebro-spinal fluid or naso-pharynx of the case and its correct type diagnosed by agglutination, and not infrequently 72 hours pass before the infecting meningococcus is classed.

An attempt was made in the first place to shorten this period by substituting a precipitin for the agglutination reaction; it failed dismally. Finding that in case of the four univalent agglutinating sera prepared from the rabbit and sent out from the Central Laboratory for identifying types of the meningococcus the results given by complement-fixation were practically identical with those obtained by agglutination, the writers next proceeded to apply the complement-fixation test to serum taken from patients at an early stage of cerebro-spinal fever, using the four standard type cocci as antigens in each instance. The results obtained in 16 successive cases of cerebro-spinal fever were as shown in the table given below.

It will be seen that in each of the 16 cases except (*b*) the results were not clean-cut. Nevertheless, the indication obtained by this method was proved right in all of the cases in which the type of the coccus could subsequently be verified by agglutination of the culture isolated from the cerebro-spinal fluid or naso-pharynx of the patient. Contrary to the experience of some other workers, it was found with one exception that there were too few antibodies in the patient's sera to produce agglutination with the four type emulsions.

Serum Control, 1 : 50, negative in each case.

†††, Complete complement fixation (absence of hæmolysis).
–, Negative fixation (hæmolysis complete).

Controls of normal serum from several sources were carried out in each instance and gave uniformly negative results. Serum from four syphilitic and eight gonococcal cases also gave either negative results or very slight complement fixation, and then only at a dilution of serum of 1 : 50. A sample of serum from a case (1) which subsequently was regarded to be one of tuberculous meningitis gave a positive result. The explanation of this is not yet clear. The earliest day on which a positive result was obtained was the third, but the history may have been incorrect, and this point wants verifying. The case indicated as "h" in the table shows the difference in antibody content of three specimens of blood collected on the third, fifth, and twenty-eighth days of the disease respectively.

Technique.—Two different antigens have been made use of so far. At first suspensions of the stock cocci were used in a strength of 200 million organisms per c.cm., this strength being chosen because an emulsion of 400 million per c.cm. was found to be slightly anticomplementary. Later, at the suggestion of Captain Thomson, of the Military Hospital, Rochester Row, who has been studying the test in relation to gonococcus infection, an antigen was made by dissolving the cocci in N/20 NaOH and bringing the solution back almost to the neutral point by the addition of N/20 HCl. This antigen is used in a dilution equivalent to 100 million cocci per c.cm. It is found to be a much more sensitive antigen than the stock suspension, though less specific with a serum rich in antibodies.

The patient's serum is tested in dilutions of 1 : 50, 1 : 100, and 1 : 200. It is found to be advisable to use all three dilutions for each test, as the readings are not sufficiently clean-cut for a single dilution only to be used. A sheep hæmolytic system is used and complement is obtained from the ear of a guinea-pig.

In the titration of the complement the following method is followed:—

Increasing doses of a 1 : 10 solution of complement—viz., 0·15 c.cm., 0·2 c.cm., 0·25 c.cm., &c.—are added to tubes already containing antigen and 1 : 50 normal human serum in the proportions subsequently used in the actual test. These are incubated in the 37° C. water-bath for half an hour before the hæmolytic couple is added. The exact amount of complement required to bring about complete hæmolysis under these conditions is then used in the test proper. A control is put up of the serum of the patient without the antigen and a further control of the antigens only.

THE Johannesburg Municipal Council has appointed Dr. A. J. Milne acting medical officer of health, during the absence of Dr. C. Porter, at a salary at the rate of £2000 per annum.

A NOTE ON

THE LOSS OF COMPLEMENTING POWER IN KEPT SERUM.

BY J. S. C. DOUGLAS, D.M. OXON., M.SC. BIRM.,
A TAIN, R.A.M.C. (T.F.); PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF SHEFFIELD;
AND
J. W. BIGGER, M.B., B.CH. DUB.,
DEMONSTRATOR IN PATHOLOGY IN THE UNIVERSITY OF SHEFFIELD.
(*From the Department of Pathology and Bacteriology in the University of Sheffield.*)

THE laws governing the disappearance of complement from sera are of the utmost importance in the elucidation of the problem of complement-fixation in the various "lytic" and other phenomena. Owing to the difficulties in the determination of even the simplest instance of the loss of complementing power—i.e., in kept normal serum—the literature only contains vague and contradictory statements, such as:—

Complement "disappeared spontaneously if the serum was kept for a few days" (Emery [1]); "Alexines are of the most unstable nature" (Ehrlich and Morgenroth [2]); "Rapidly, often within 24 hours, loses its strength when kept at room temperature" (Muir and Ritchie [3]); at 10° C. serum possesses only half its original strength at the end of 24 hours (Noguchi and Bronfenbrenner [4]); whilst Massol and Grysez,[5] without indicating their methods of investigation, give some determinations showing that the complementing powers of sera decrease rapidly at the commencement, becoming inactive by about the sixteenth day.

We have therefore endeavoured to determine the rate of loss of complementing power in kept normal serum in order to ascertain whether it is a regular phenomenon obeying definite physico-chemical laws. To this end we have elaborated a technique whereby the hæmolytic complement content of a kept serum can be ascertained with some exactitude from day to day.

The chief difficulty in such an investigation is in the preparation of standard suspensions of red corpuscles, which can be kept for the purpose of the determinations. This we have overcome by using sheep cells washed and stored in the manner described by Rous and Turner,[6] since we find that the susceptibility of such cells to hæmolysin, although somewhat increased during the first 48 hours, subsequently appears to remain nearly constant for a greater length of time than that covered by our experiments. We therefore allowed at least 48 hours to elapse before using the cells, and in this way obtained a preparation suitable for the investigation. The preserved sheep cells were washed free of Rous and Turner's fluid with sterile normal saline and suspended in the latter in such strength that the hæmoglobin liberated by distilled water and treated with CO was exactly twice the strength of that in the standard tube of a Haldane-Gowers hæmoglobinometer. This method allows of accurate standardisation of the test corpuscular suspension day after day when made from the same batch of preserved blood, the suspension of red corpuscles of this particular density being termed the "standard corpuscular suspension."

Complement was obtained from guinea-pigs with aseptic precautions. The blood after collection was allowed to clot and the separated serum centrifuged to free it from corpuscles. This serum was stored at the desired temperature, the amount necessary for each determination being withdrawn with a sterile pipette and immediately titrated. Each of the sera A, B, and C was obtained from a single healthy adult animal.

The immune body was a rabbit anti-sheep cell serum of high titre which was always used in the same dilution, so that three hæmolytic doses were present in each of the titration tubes.

Titration of Complement.

The complement-containing serum was so diluted as to cause standard hæmolysis in an amount between 1 c.cm. and 0·1 c.cm. of the dilution. Of this dilution 1·0, 0·8, 0·6, 0·5, 0·4, 0·35, 0·3, 0·25, 0·2, 0·17, 0·13, 0·1 c.cm. were measured into small test-tubes of similar diameter which already contained sufficient saline to make the total volume in each tube 1 c.cm. As a control another tube containing 1 c.cm. of saline was prepared. To each was added 1·5 c.cm. of a mixture of two parts of standard corpuscular suspension and one part of diluted immune body. The tubes were shaken, placed in a water-bath at 37° C. for two hours, then removed, shaken, and allowed to settle in the ice-chest till the following day, when the amount of serum required to produce standard hæmolysis was noted. Standard hæmolysis is equivalent to the hæmolysis of 60 per cent. of the added corpuscles. It was determined by comparing the colour in a similar tube containing 0·6 c.cm. of the standard corpuscular suspension hæmolysed and made up to 2·5 c.cm. with distilled water with the colours obtained in the titration tubes. It was thus found possible to make a very accurate estimation of the position of standard hæmolysis in the series by inspection. The strength of complement found in each specimen of serum is expressed in arbitrary units by multiplying the reciprocal figure of the actual amount of diluted serum giving standard hæmolysis by the number of times the serum was diluted.

The Experiments.

The experiments consisted in submitting complement as soon as it had been obtained free of cells (i.e., 21·5 hours after the collection of the guinea-pigs' blood) to temperatures of 9° C. in the case of sera A and B and 20° C. in the case of serum C, light being excluded. The temperatures were maintained as nearly constant as practicable until the removal of samples for titration had exhausted the specimens. The times at which the samples were taken and the number of units of complement found at the different intervals is recorded in the table for all three sera, whilst graphs of the results in the cases of sera B and C are also given. The duration of the experiments was, for A, 211 hours; for B, 305·5 hours; and for C, 186 hours.

Consideration of the Results.

An examination of the figures given in the table and of the curves shows that as time progresses the complement decreases, but that it has not completely disappeared at the times when the sera were exhausted, the percentages of the original strengths remaining at the final estimations being 16·1 (A), 11·2 (B), and about 7 (C). This decrease is rapid at first but later proceeds more slowly, both absolutely and relatively: for during the first 50 hours the complement falls from 279 units to 164 (A), from 258 to 151 (B), and from 222 to 93 (C)—i.e., a loss of 41 per cent. (A), 41·5 per cent. (B), and 58 per cent. (C), whilst during the same length of time between the 136th and 186th hours the fall in complement is from 77 units to 53·3 (A), from 83 to 57·5 (B), and from 30 to 18 (C), drops of 30·5 per cent. (A), 30·5 per cent. (B), and 40 per cent. (C).

These figures also prove that the loss is more rapid at the higher temperature, since Sera A and B were kept at 9° C. and C at 20° C., a point which is further emphasised by comparing the lengths of time required for a loss of 75 per cent. of the original strengths—i.e., 85 hours at 20° C. (C), 150 hours (A), and 169 hours (B) at 9° C, the loss at 20° C. taking about half the time which is required to produce the same change at 9° C.

The curves of loss of complementing power in the case of each serum are very regular throughout the ranges covered by the experiments (i.e., 1 to 1/6, 1 to 1/9, and 1 to 1/12), and the results are capable of being expressed by the formula $\frac{dx}{dt} \cdot \frac{1}{x^{n+1}} = K$, as can be seen in the table, where appear the figures calculated for each experiment from this formula after the graphic method given by Madsen.[7]

In this differential equation x is the amount of complement remaining after the lapse of t hours, n and K being constants.

Remarkable similarity is to be noticed between the results obtained experimentally and those calculated. In Experiment A, conducted at 9° C., there is only one point of marked deviation—namely, that at 114·5 hours, which seems to be due to some accidental experimental error. In Experiment B, also at 9° C., no error of such magnitude is present, the correspondence between observed and calculated results in both cases being highly satisfactory. Experiment C presents only moderate agreement between the calculated and the observed figures, but nevertheless is sufficient to indicate that the same formula may also hold good at 20° C., as will readily be seen by inspection of the table and the curve, in which the observed points and the theoretical curve are shown.

Conclusions.

1. A satisfactory method of estimating decreases in the complementing powers of sera over considerable periods of time has been devised.

2. Whilst kept normal guinea-pig serum loses its complementing power more rapidly in the early stages than the later, and at 20° C. than at 9° C., yet it retains its activity for a considerably longer time than has generally been conceded.

3. The loss of complementing power of such serum is perfectly regular and can be expressed by the formula— $\frac{dx}{dt} \cdot \frac{1}{x^{n+1}} = K$, at 9° C., and apparently also at 20° C.

KALA-AZAR IN MALTA: TWO CASES TREATED BY INTRAVENOUS INJECTION OF TARTAR EMETIC.

BY H. I. WINIFRED KERR, M.B., CH.B. GLASG.,
ATTACHED R.A.M.C.

ALTHOUGH the occurrence of the infantile variety of kala-azar in Malta is well known to medical men practising in the island, it was believed until recently that the adult variety did not occur. Lately several cases have been described among military patients in which the disease developed in Malta. One such has been described by Lieutenants Brodie and Yorke,[1] and Captain G. R. Ward has contributed to THE LANCET[2] a short note on two cases in which the disease developed after the return of the patients to England.

In the present paper two further cases are recorded. One patient came direct from England to Malta and had never been further East; the other patient had been invalided from Gallipoli with amœbic dysentery more than a year before he developed kala-azar, having been in "convalescent employ" in Malta. However, the cases acquire far greater interest and importance in that treatment by intravenous injection of tartar emetic, recently introduced by Sir Leonard Rogers,[3] was conspicuously successful, recovery being to all appearance complete and permanent. In Case 1 diagnosis was reached at an early stage, and the response to treatment was much more rapid than in Case 2, where patient was ill several months before treatment was initiated.

The recognition of kala-azar presents no special difficulty when one is on the lookout for it. In the early stages the diagnosis rests upon general weakness and wasting, with raised temperature, sweating, conspicuous splenic enlargement, and pronounced leucopenia, this consisting of a marked relative diminution of polymorphonuclears and relative increase of mononuclear cells. The characteristic temperature chart, with its double daily rise, does not become conspicuous until rather later. For confirmation of the diagnosis splenic or hepatic puncture is necessary. Relying upon the signs mentioned above the diagnosis of yet a third case in one of the military hospitals was made within a few days of the patient first reporting sick.

[2] THE LANCET, 1916, ii., 16.
[3] THE LANCET, 1916, ii., 782.

It is obvious that the treatment by tartar emetic should be resorted to in such cases as soon as the disease is recognised, for the cases here recorded tend to confirm its great value in a disease regarded hitherto as of specially evil prognosis.

CASE 1.—Sister B. Admitted Sick Sisters' Hospital Jan. 23rd, 1917. Age 29 years. Service 1 7/12 years. Had never been further east than Malta. Patient arrived on island in July, 1915; enjoyed good health till November, 1916, when she began to feel tired and more weary than usual. Slight cough in January, 1917; on Jan. 23rd T. 100·8° F. She reported sick. Nothing abnormal detected in heart or lungs. Abdomen moved freely; on left side was a mass, some doubt whether it was enlarged spleen or kidney. Urine acid; sp. gr. 1008; trace of albumin; a few granular and hyaline casts, no tubercle bacilli. She ran high T., which began to show indication of two rises in 24 hours from Feb. 12th; occasional rigor. Blood negative to Widal's reaction; no malarial parasites found. Diminution of both red and white cells; hæmoglobin fell from 52 to 30 per cent. Amenorrhœa for two months; no diarrhœa.

On findings of blood picture, the leucopenia, marked anæmia, suggestive temperature, with mass in left side, now undoubtedly an enlarged spleen, splenic puncture was advised; Leishman-Donovan bodies recovered. In neither case could these parasites be recovered from peripheral circulation, nor from serum of blisters.

On March 1st intravenous injections of 2 per cent. solution of antimony tartrate were commenced, and continued in increasing doses at four days' intervals, beginning with 4 c.cm. The first injection (2/3 gr.) was well borne; no marked reaction. By March 21st blood picture had improved; T. only slightly raised; patient had menstruated first time for three months. Spleen, which had been below umbilicus, had not altered much hitherto, but by March 24th lower border was ½ inch above anterior iliac spine. About April T., which had been normal, rose to 100°; an injection given at once checked relapse. After first six injections intervals between had been gradually increased and had evidently become too long.

By May 31st spleen was only four fingers' breadth below costal margin; left kidney again palpable, low and enlarged. By June 5th spleen was not palpable and remained so without further treatment. Regaining weight; no rise of T. Patient was subsequently returned home as a "walking case" and has now, we understand, resumed duty in a military hospital in England.

CASE 2.—Corporal C. Admitted Military Hospital, Imtarfa, Feb. 18th, 1917. Age 28. Service: 3 1/12 years. Foreign service: Egypt, September, 1914–August, 1915; Gallipoli, August, 1915–Oct. 28th, 1915; Malta, Nov. 3rd, 1915. Patient's health good during year in Egypt, and in Gallipoli till invalided with amœbic dysentery in October, 1915. On recovery stool examined at Camp Hospital; found to be carrier of *E. histolytica*. He was treated from May till July, 1916, at Imtarfa Hospital, being discharged back to Camp Hospital on July 9th, 1916. There he became a "convalescent employed" on orderly-room staff. There were plenty of fleas about, and a dog attached to the orderly-room slept frequently on his bed and had special attention as it was then suffering from "distemper."

About end of 1916 patient began to feel very tired; was getting thinner. In January, although taking quinine, 10 gr. daily, T. rose. In beginning of February he was having 20 grains daily; T. not controlled. Eventually he was sent into hospital again as case of P.U.O. Nothing abnormal in heart or lungs. In abdomen tumour below left costal margin, about hand's breadth downward. It was not tender; apt to vary in position Patient markedly emaciated; a curious greyish complexion. Carefully charting, it was noticed that T. rose twice in 24 hours, often as high as 104° or 105°. No symptoms of dysentery; stool reports negative. Quinine given intramuscularly; no effect on T. Blood did not agglutinate dysenteries, typhoid, paratyphoid bacilli, nor *Micrococcus melitensis*. No malarial parasites found in films taken; marked leucopenia and anæmia. These, with spiking of temperature and enlarged spleen, led to suggestion of splenic puncture. On account of extreme debility hepatic puncture was resorted to and *L. donovani* recovered.

On March 7th treatment by tartar emetic in 2 per cent. solution (normal saline) was commenced with 4 c.cm. intravenously, increased by 2 c.cm. and given every three days, till 10 c.cm. were reached. Marked general reaction each time. Reactions, with patient's debility and nervous condition, induced one to try ¼ gr. of morphine and 1/60 gr. of strychnine hypodermically, 20 minutes before injection. This had a good effect, quieting general reaction of coughing, retching, and hysteria, and abolishing entirely rigor which used to come on about two hours after injection. The 10 c.cm. dose had to be given within at least 60 to 90 seconds, or coughing and retching would begin, and it became impossible to keep needle directly in vein. Tartar emetic causes an intense inflammation should any escape, followed by cold abscess. Two of these occurred, but cleared up with treatment. There is less reaction when solution is heated to blood heat.

By March 26th patient was being given 10 c.cm. doses of tartar emetic, 2 per cent. solution; condition critical. T. still rose to 104° twice daily; P. 120. Heart sounds fairly good; no dilatation or murmurs. His condition got steadily worse. He suffered greatly from night sweats. As condition was desperate, drug was pushed to its limit, and on March 31st 12 c.cm. of solution were given, followed by 10 c.cm. every other day until April 16th, when T. rose once only to 101°. General condition much improved. T. did not rise again, and as his arms were very sore and suitable veins were not obtainable elsewhere a week's respite was allowed, during which time T. did not rise. Veins showed signs of inflammation and leakage at previous punctures where the solution had been given. 10 c.cm. and then 6 c.cm. were given at intervals of a week, but T. rose again with a smaller dose, with drowsiness and lack of appetite. On May 27th he was given 10 c.cm. and then 9 c.cm. of solution at interval of three days. This controlled relapse and two more doses completed this treatment. The spleen by July 11th was only just palpable below costal margin.

During treatment patient suffered from no skin eruptions nor rashes, no gastric disturbances, no diarrhœa, and no ophthalmic symptoms. He was transferred to England as a "walking case," and writes that he has now taken up former occupation. Except for the melancholy and depression, the antimony had no toxic effects, though given in such large and frequent doses; also no return of dysentery. Altogether he had 424 cg. of tartar emetic; 246 cg. of tartar emetic being used in Case 1.

Unless the period of incubation of kala-azar be longer than one year, we may safely conclude that in both cases the disease was contracted in Malta, and probably from the bites of insects. In Case 1 there was ample opportunity of being bitten by fleas and bugs, as the patient worked during the time that barracks were being converted into hospitals, and also during the height of the Gallipoli campaign, when patients were arriving direct from the firing line. In Case 2 one would specially incriminate the dog, with its fleas, though the parasite was never recovered from its peripheral blood. Both these cases occurred about the same time, at the beginning of the year 1917, but in different parts of the island.

I am deeply grateful to Dr. May Thorne, attached R.A.M.C., to whose kindness I am indebted for her notes on Case 1; also to Dr. E. J. Dalyell, attached R.A.M.C., who was responsible for the practical treatment of the case. I have to thank most of all Colonel Sir A. Garrod, F.R.S., but for whose aid these notes would be as yet unwritten; and also Colonel G. B. Price, officer commanding Military Hospital, Imtarfa, for kind permission to publish them.

Reviews and Notices of Books.

An Enquiry into the Analytical Mechanism of the Internal Ear. By Sir THOMAS WRIGHTSON, Memb. Inst. C.E. With an Appendix on the Anatomy of the Parts Concerned by ARTHUR KEITH, M.D., F.R.S. London: Macmillan and Co., Ltd. 1918. Pp. 254 + 9. Price 12*s.* 6*d.*

SINCE 1863, the year in which Helmholz published his classic on the physiology of hearing, much work has been done on the finer anatomy of the cochlea, but hitherto no corresponding advance has been recorded with regard to the physiology of hearing. There has been an increasing rejection of the Helmholz theory, especially among those with large clinical experience of the disorders of hearing, but no valid new theory of the mechanism of hearing has been proposed. The heart of the difficulty has been the question of the resolution in consciousness of compounded vibrations into their constituents. Helmholz saw no method by which this was possible, except his postulate of sympathetic vibration in the cochlea. As a physiological means for this he found no structure but the fibres of the basilar membrane, and in spite of the obvious difficulties he was content to accept it and build on this foundation. The foundation was unsatisfactory, and the theory of hearing has remained hampered by this moribund faith. We are now in a position to welcome a distinct and better theory. Sir Thomas Wrightson has been able to bring an almost life-long study of aerial wave-form into combination with an engineer's survey of the cochlea viewed as a machine. Professor Keith, in his luminous appendix, has clarified the anatomical considerations and strengthened the position of the theory by a consideration of the comparative anatomy of the cochlea.

In the consideration of the Wrightson theory the first point to be grasped is the real nature of the sound wave. The ordinary graph of a simple tone is a simple "zig-zag" wave-line, and, as Professor Keith acknowledges in his own case, has generally been misinterpreted as implying a stimulus in hearing of two phases, at the top and bottom of the alternating curve. This error has led to much difficulty. The "wave" is really a pressure variation passing from a zero position to a maximum, reversing direction, passing through zero, continuing to a minimum, reversing once more, and returning to zero. There are thus in the cycle not two but four positions of definite change and so of stimulus, at the maximum and minimum and at the crossing of the zero lines, at each of which points the direction of change is reversed. Now when two simple tones are sounded together their respective wave-forms are combined into a graph which varies in outline with the phase position in which the two curves happen to overlie each other, and at first, in even so simple a case, the result is indecipherable. By means of an ingenious machine which he calls an "ohmograph" Sir Thomas Wrightson has recorded a very large number of such compound curves of varying complexity, and has applied the four-stimulus theory to their analysis. In the result he has been able to show that while the resultant curves lose all obvious relation to the elementary curves which are plotted beside them by the machine, they are still capable of analysis, and show the survival of the changes of direction of their constituents. In other words, the compound wave may still be regarded as the simultaneous occurrence of the original rhythms, and if we grant a preferential consciousness for rhythmically repeated auditory stimuli all we need demand in the cochlea is an apparatus capable of yielding a stimulus at every change of direction in the pressure wave, simple or compound, as it arrives at the ear.

Turning now to the more directly physiological part of the inquiry, both authors accept the usual interpretation of the tympanic structures in its broad outlines. Two points need mention: the footplate of the stapes acts not as a piston, but as a hinged plate moving round its antero-inferior border, and the intrinsic muscles form an opposed pair, the tensor tympani pushing in the footplate while the stapedius pulls it out. The mean position is thus one of extreme instability, capable of being affected by the smallest pressures in either direction within a limit determined by the tension of the muscles. An important accessory resistance, not noticed by either author, is afforded by the radial fibres of the membrana tympani. The pressure variations of the sound wave thus arrive in all their complexity and fineness and are transmitted without change of period. At this point they pass from an elastic compressible medium to an incompressible one, and their physical character undergoes a corresponding change, and becomes a movement of direct translation of the perilymph. This perilymph pulse passes from the footplate of the stapes to the membrane of the round window, and in its passage evokes the essential stimulus. The elucidation of the nature and mechanism of this stimulus is the central point of the theory.

In relation to this problem Professor Keith in his appendix reviews the history of our knowledge of the structures of the scala media of the cochlea. The inadequacies of the Helmholz theory of resonators provided by the fibres of the striate zone of the basilar membrane are reviewed once more. The question is what are the physical happenings in the cochlea under the passage of a single pulse of sound. Clearly a displacement wave commences at the footplate during the compression phase and passes to the secondary membrane, subsequently reversing and bringing the footplate of the stapes back to its mean position, the volume displacement of the secondary membrane being equal to that of the footplate. But by what path is the volume movement transmitted? Neglecting the lax and easily displaced membrane of Reissner, the cochlea may be considered as two adjoining passages, closed as to one pair of ends by the footplate and the secondary membrane respectively, and communicating at their other ends by the narrow vent of the helicotrema. The party wall between the two passages is formed in part by the rigid bony shelf of the lamina spiralis ossea, in part by the basilar membrane. The latter again falls into two subdivisions, an inner elastic arcuate zone and an outer firmer striate zone. Standing on and practically limited to the arcuate zone is the organ of Corti, overhung by and in contact with the tectorial membrane. The aperture of the helicotrema is small and remote from both the moving diaphragms in the two windows; and the fluid friction involved in the passage of waves through the whole length of the double passage and the throttle hole of the helicotrema would probably damp out all but the strongest vibrations. On the other hand, the displacement will pass readily and directly from the upper to the lower passage across the membrana basilaris, displacing it correspondingly according to the phase of the pulse. The finer structure of the membrana basilaris is shown by Professor Keith to be admirably adapted for such elastic displacements. Accepting this, what happens in the organ of Corti? This has been elucidated by both authors, but with fine analysis by Professor Keith using scale models. It is shown that owing to the form and structure of the basilar membrane and to the arrangement of the rods of Corti and the supporting fibres of Deiters, the upward and downward swing of the membrane is transformed into a lateral movement of the surface of the organ of Corti. From this surface project the hairs of the sensory hair-cells, passing into the under surface of the relatively fixed tectorial membrane. The hair-cells with their supports thus move laterally under the tectorial membrane with each pulse of the sound wave, the hairs are deflected in correspondence with these movements, and undergo a change

in direction of the process of deflection at each of the four "stimulation points" of the complete cycle of a simple sound wave, and at each of the corresponding multiple points of a compounded sound curve.

In summary, the authors have discovered a mechanism which is capable of registering every complexity of the compounded wave and of passing it on to the sensorium in accurate record as nerve impulses. The final process of the appreciation of these impulses as simple or compounded and harmonised notes is of course central. In this beautiful theory we have at last an intelligible account of the genesis and nature of the peripheral stimulus concerned in the sense of hearing. It is, moreover, of special interest that the nature of the stimulus in the cochlea is essentially the same as that in the primitive mixed vibrational and positional organs of such creatures as the crustacea, and as that of the sister tracts in the vestibule and semicircular canals. We rejoice that we can claim so important a theory as British.

A Manual of Bacteriology, Clinical and Applied. By R. TANNER HEWLETT, M.D., F.R.C.P., &c., Professor of Bacteriology in the University of London, Director of the Bacteriological Department, King's College, London. Sixth edition, with 31 plates and 69 figures in the text. London: J. and A. Churchill. 1918. Pp. 769. Price 14*s.* net.

THIS manual is intended to provide such information in bacteriology as is required by the medical student, the practitioner, and the medical officer of health, and as it has now reached its sixth edition proof is not wanting that it has served its purpose. The difficulty in deciding how much of the large amount of work which is being produced at the present time is of permanent value has made the re-editing a task of considerable complexity. War problems have largely determined the direction of medical research, and the chapter on anaerobic organisms, which have been found so closely related to war injuries, has received certain additions. To some these additions may appear disappointingly small, though both Weinberg's and Fleming's researches are included. We may suggest, however, to the author that if the new methods he has incorporated really denote an improvement in technique older methods might have been deleted for them and more stress laid upon the advantages of the new. Bacteriology is making rapid strides forward, and a time must come for the bold remodelling of a popular text-book, along with the abandoning of older and less exact methods of technique. The responsibility of the teacher in this respect is especially great now that the reading of a text-book so largely takes the place of attendance on systematic lectures.

In view of the interest excited by "epidemic stupor" the section on *B. botulinus* will probably be enlarged in a subsequent edition. The production of anaerobic conditions of culture by the use of palladium black finds a place in the chapter on methods, and this chapter has received several other important additions. Epidemic cerebro-spinal fever has furnished another war problem, and the chapter on this subject has been rewritten, while there has also been considerable alteration in the section dealing with the typhoid-colon group of organisms, together with a greatly extended table of the fermentation reactions of this group. The Oxford standard method of agglutination also naturally now finds a place. There are a number of other alterations and additions, including Chalmers's classification and nomenclature of the streptothrix infections and fuller details of the Wassermann reaction in the section on syphilis. New figures and plates have been introduced where required. The book is well produced, and leaves little to be desired in its method of presentation.

Laboratory Studies in Tropical Medicine. By C. W. DANIELS, M.B. Camb., F.R.C.P. Lond.; and H. B. NEWHAM, M.D. Dub., D.T.M. & H. Camb. Fourth edition, thoroughly revised. London: John Bale, Sons, and Danielsson. 1918. Pp. 560. Price 21*s.* net.

Dr. C. W. Daniels in his preface to the first edition of these studies stated the object of the work to be to assist practitioners in the tropics in the application of simple laboratory methods to the practice of medicine. The book therefore ranged over a large variety of loosely-bound-together subjects, including, amongst others, post-mortem examinations, parasites found in the blood and tissues and their life-history, fæces, intestinal parasites, bacteriology, measurements, and statistics. Advances in tropical medicine have been rapid and the book has been revised in the third and again in the present edition with the assistance of Dr. H. B. Newham, director of the London School of Tropical Medicine. The authors express the hope that it may be of service to the many practitioners now meeting tropical disease for the first time in the various theatres of war.

But while it contains much useful information and is lavishly illustrated, the book should not be considered in the light of a complete guide to laboratory practice. It fails to be so by attempting to deal with too many subjects, much space being consumed in elementary teaching, such as the method of making a platinum loop, familiarity with which might be assumed in the class of reader to whom address is made. While sections on protozoology, helminthology, entomology, hæmatology, mycology, pathology, water analysis, and a variety of other miscellaneous subjects are included, to mycology, a difficult subject and one unfamiliar to the non-expert, less than five pages are devoted. Those who require to investigate a case of bacillary dysentery, paratyphoid, or plague will find little or no help in the book. Information about the cholera organism is limited to the fact that it is motile and liquefies gelatine. The description of amœbic and other protozoal cysts in fæces is incomplete and devoid of figures, while a scheme of life cycle of *A. coli* is included which cannot be said to be yet established. Misleading statements also are present: e.g., on p. 69 we find it stated that "Maurer's bodies" stain blue with Romanowsky's stain, and that lymphocytes contain no azure granules; on p. 201 (Fig. 84), in the transverse section of the proboscis of *Glossina palpalis*, some of the parts shown are in the right position, others are upside down.

In making these criticisms we do not imply that a book which has reached a fourth edition is not filling a useful place, but we suggest that a careful revision would tend to greatly increase its value.

Treatment of Gonorrhœa. By N. P. L. LUMB, Temp. Capt., R.A.M.C. London: H. K. Lewis and Co., Ltd. 1918. Pp. 120. Price 4*s.* 6*d.*

THIS book is written with a view to helping those in charge of venereal clinics whose previous knowledge of up-to-date methods may have been limited. The book satisfies the need for which it was written; it is of a convenient size, and the necessary information is compactly condensed and is commendably devoid of theoretical considerations.

The methods of diagnosis and treatment not only of gonorrhœa, but also of its local and generalised complications, are gone into. All the modern methods of diagnosis and treatment are described in detail and the reason for their use explained. There is rather a tendency in the book to suggest that vaccine-therapy is of primary importance, which may or may not be the view of the author, but to some it will appear that this importance is a little unduly emphasised. Valuable enough as vaccines may be, although this is debatable, it is a little unwise even to suggest to the mind of those who are not familiar with their use that they play a prominent part in the treatment of localised gonococcal infection. To lay too much stress on their use and omit the other forms of treatment is a perilous error. The book deserves to be well received by those for whom it is written; it is full of practical counsel.

A History of Departed Things. By Mrs. HENRY HEAD. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 1918. Pp. viii. + 242. Price 3*s.* 6*d.* net.

THIS record of a woman's thoughts and experiences, expressed in letters, will appeal to medical readers on many grounds. The heroine, the daughter of an Oxford professor, is twice married, and both husbands are members of the medical profession. The glimpses into Harley-street life and into the work of country medical practice are truthful and attractive. The heroine is a living, loving, much troubled woman, and her story a psychological study of temperament and disposition. In selecting the epistolary form of presentation Mrs. Head has taken grave risk, but the result justifies the experiment, as her work will bring refreshment to harassed and tired minds.

JOURNALS.

The Journal of Physiology. Edited by J. N. LANGLEY, D.Sc., F.R.S. Vol. LII., No. 1. Cambridge: University Press. 1918. Pp. 1–74. Price 7*s.*—The Guanidin Content of Muscle in Tetania Parathyreopriva, by Pearl S. Henderson. The symptoms of tetania parathyreopriva have correlated with the action of guanidin on the spinal cord, while an increase of guanidin in blood and urine has also been observed. The author finds that there is a fall in the total and in the free guanidin of muscle and a rise in the creatin. The fall in the total guanidin is far in excess of the nitrogen in free guanidin and creatin, and must indicate either a liberation of guanidin from the muscle or a failure in the power of the muscle to take up guanidin formed elsewhere, either of which may be correlated with the increase in the blood and urine.—The Velocity Factor in Cardiac Work, by C. Lovatt Evans. The energy expended in imparting velocity to the blood is very considerable, both under experimental conditions in animals and in the human heart during exercise.—Observations on the Atrophy of Denervated Muscle, by J. N. Langley and M. Hashimoto. This elaborate research extends to over 50 pages, and deals with so many aspects of the question that in the space at our disposal we can only refer to a few of the authors' conclusions. After describing the two methods—bilateral and unilateral denervation—in animals to determine to what extent a given treatment retards the atrophy of denervated muscle, the authors describe their results in bilateral denervation and the effects of some forms of treatment, such as ionisation with calcium and potassium salt, Ringer's fluid, rhythmic flexion, and extension and massage. In unilateral denervation the rate of atrophy, absolute and relative, in different muscles, is discussed. The normal difference in weight of the muscles of the two sides usually varies within rather narrow limits. The chief difficulty in experiments on the leg of the rabbit is that of preventing trophic changes in the foot and skin of the leg. Reviewing the effect of the various forms of treatment tried by them, the authors think "there is only one which gives any hope of considerably reducing the rate of atrophy—viz., ionisation with a potassium salt, and that is slender." The impression they got from the present and past experiments is "that none of the methods of treatment of denervated muscle now in use—passage of galvanic current, production of contraction, passive movements and massage—can have more than a slight effect of delaying muscle atrophy." On the Creatin Content of Skeletal Muscle in Degeneration following Denervation, by E. P. Cathcart, P. S. Henderson, and D. Noël Paton. Most of the experiments were made on cats, a piece of one sciatic nerve being removed to prevent regeneration. Up to the eleventh day there seems to be no distinctive change in the creatin content of muscle. After the fifteenth day, when the reaction of degeneration is well established, there is a steady and progressive decrease in the creatin content. The results point to the association of creatin with the sarcostyle element of the fibre.

The American Review of Tuberculosis. Baltimore: National Association for the Study and Prevention of Tuberculosis. Price 35 cents.—The April issue contains three papers on Artificial Pneumothorax. Dr. W. B. Kendall and Dr. C. C. Alexander, with an experience of 131 cases, report favourably on this treatment. They reserve it, as a rule, for severe or moderately severe cases, but in one early case they resorted to this measure to check a troublesome cough that had been refractory to other treatment.—Dr. Saling Simon and Dr. Samuel Swezey record a case of Pulmonary Abscess treated with artificial pneumothorax. The beneficial results were dramatically rapid and permanent.—In a paper on Pleural Shock Dr. J. B. McKnight, Dr. H. F. Gammons, and Dr. W. M. Knowles give an account of the one case of pleural shock observed by them in a series of 65 cases and about 800 punctures of the chest. It has been their practice to inject cocaine in every case, but not to give a preliminary injection of morphine. Their patient was a nervous young man, who had already been given several injections of air. At one operation the manometer showed no oscillation, and the operator was therefore about to withdraw the needle when the patient suddenly sat up without warning. Then he sank back unconscious, frothing at the mouth, breathing stertorously, and exhibiting tonic contractions of the whole body. For two days there was complete loss of vision. The authors regard the ocular symptoms as indicative of hysterical amblyopia, and they assume that the case was one of pleural shock, not embolism, because no gas had been introduced through the exploring needle. They do not mention the possibility that the needle may have wounded a blood-vessel into which inspired air may have been sucked. Their treatment included an injection of gr. ¼ of morphine, which proved useful.—In a paper on elementary conceptions of tuberculosis Dr. A. K. Krause pleads for systematic supervision in after years of children who have successfully run the gauntlet of infection in infancy, but who, if left to themselves, will swell the ranks of the adult consumptives.

New Inventions.

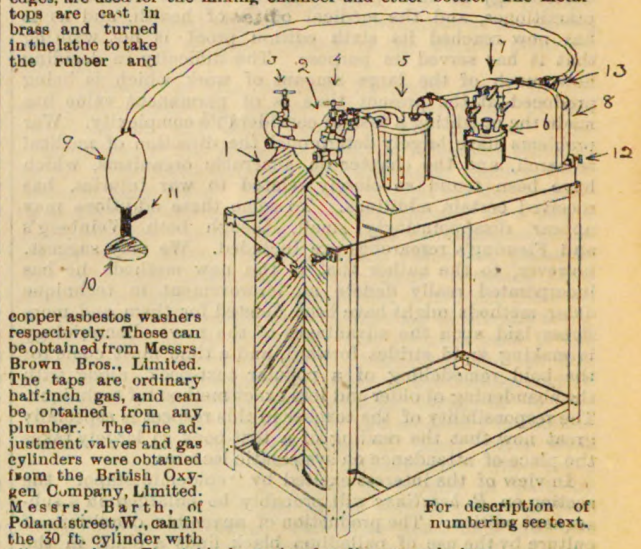
A COMBINED GAS-OXYGEN, GAS-OXYGEN-ETHER AND WARMED-ETHER APPARATUS.

THE success obtained by Gwathmey by the administration of gas oxygen suggested the construction of this apparatus.

It consists of an enamelled iron table, supporting at one end in a suitable casing a vertical 350 gal. cylinder of nitrous oxide (marked 1 in figure) and a 30 ft. one of oxygen (2). On the table is fixed a glass mixing chamber for the gases (5), with visible feed, an ether bottle (6) through which the gases can be directed at will, and a jacketed worm (8) for warming, if such is desired. To each cylinder a fine adjustment valve (3, 4) is attached. These regulate the flow of nitrous oxide and oxygen respectively through the glass cylinder of water. The oxygen tube has three and the nitrous oxide five visible lateral holes; thus from the number of holes bubbling the proportion of the two gases can be seen. The gases pass either directly to the breathing bag (9), if desired through a worm (tap marked 13) immersed in hot water, for warming, or may be directed through a water-jacketed bottle containing ether by means of tap (7). The table is of convenient height, so that the anæsthetist can be seated at the patient's head, holding the face-piece (10) in one hand, and having the other hand free to regulate the control taps.

The water and ether bottles are supported on a rubber cushion. The metal tops are attached in the same way as the lid of an acetylene generator, fly-nuts screwing down on studs fixed to the stand and passing through the cover, making by means of rubber and copper asbestos rings gas-tight joints. The transmitting pipes are also held in rubber-cushioned attachments. Originally a thermos flask was employed for warming the gases, but as this did not allow of a good sized coil a metal container was substituted (8). A tap is fitted (12), so that the water can be quickly run out when cool and fresh hot water added. A screw-cap permits the addition of ether to the ether chamber.

Wide-mouth glass bottles (80 oz. and 20 oz.), cut down with ground edges, are used for the mixing chamber and ether bottle. The metal tops are cast in brass and turned in the lathe to take the rubber and copper asbestos washers respectively. These can be obtained from Messrs. Brown Bros., Limited. The taps are ordinary half-inch gas, and can be obtained from any plumber. The fine adjustment valves and gas cylinders were obtained from the British Oxygen Company, Limited. Messrs. Barth, of Poland street, W., can fill the 30 ft. cylinder with nitrous oxide. The table is made of ordinary angle iron.



For description of numbering see text.

For warm and intratracheal ether a No. 2 Fletcher blow-pipe bellows is attached to the nitrous oxide pipe. If desired, a pressure gauge can be screwed to the ether chamber. Oxygen can be administered at the same time

The technique is as follows:—A preliminary narcotic of morphia 1/12 gr. and atropine 1/100 gr. is given 20 to 30 minutes before. The valves are regulated so that four nitrous oxide holes and one oxygen hole are bubbling. The breathing bag is lightly filled with this mixture. A Bellamy Gardner mouth-prop is introduced and a well-fitting face-piece applied. The Colman gas valve (11) is turned to valves and the bag kept moderately distended. After about 10 respirations re-breathing can be commenced, turning to valves at every 7 to 10 respirations. The proportion of nitrous oxide to oxygen is usually kept at 4 to 1, the colour of the patient being the guide for additional oxygen. Cyanosis should not be permitted.

To deepen the anæsthesia the ether taps can be opened; this need be but for a few respirations. During the division of nerves or bone cutting it is advisable also to pass the gases through the ether. Re-breathing to a certain extent is good for the patient. Practically about one third of the volume of each respiration should be of freshly added gas mixture. With less there is a liability (in long cases anyway) to post-operation headache and nausea.

The advantage of nitrous oxide and oxygen, with re-breathing and ether, when necessary, has been demonstrated by Gwathmey, Page, Flemming, and Boyle. For nerve resections, amputations of the breast, removal of sequestra, varicose veins, it seems ideal. Where perfect relaxation is needed, as in gall-bladder operations, orthopædic wrenchings, appendicectomies, hysterectomies, it is not so suitable, though it can be given for this purpose.

CHARLES T. W. HIRSCH, M.R.C.S., L.R.C.P. Lond.,
Temporary Captain, R.A.M.C.; Anæsthetist, Military Orthopædic Hospital, Samaritan Hospital, &c.

Modern Views on Diabetes.

DIABETES has long been known to be characterised by the excretion of glucose, and the usual treatment of the disease has been by the elimination of carbohydrate from the diet. Nevertheless, patients still excrete sugar, and we shall be excused if we enumerate, for the sake of clearness, the views which are generally accepted on this matter. The source of the sugar has been traced to protein. Protein consists of some 18 amino-acids; some of these, such as glycocoll, alanine, glutamic acid, are converted into glucose not only in experimental animals (depancreatised, phloridzinised), but also in diabetic patients. Others are not convertible into glucose. Another origin of carbohydrate is fat; such a transformation occurs in hibernating animals and has been found to take place in some diabetics; it is not of outstanding importance. The glucose excretion is not the only symptom of diabetes. In severer cases the acetone bodies, acetone, aceto-acetic acid and β-oxybutyric acid, are produced and excreted. Acetone is a decomposition product of aceto-acetic acid and is not the primary product. Aceto-acetic acid and β-oxybutyric acid are interconvertible in the body, but the main conversion in the body is that of aceto-acetic acid into β-oxybutyric acid by the process of reduction. The liver is the organ which is mainly, if not entirely, concerned in this mechanism. Aceto-acetic acid is the primary product; β-oxybutyric acid is the safeguard. The production of acid was formerly attributed to be the cause of diabetic coma, hence the treatment with sodium carbonate, which was not really effective. Acidosis is not the cause of coma, but the toxic action of aceto-acetic acid. The term ketosis, as aceto-acetic acid is a ketonic acid, is suggested to distinguish this action from acidosis. The fat of the food has been proved to be the source of the aceto-acetic acid, but it may also arise from protein. Though aceto-acetic acid can theoretically be derived from carbohydrate, this source may be excluded. To sum up—the glycosuria arises from the carbohydrate and the protein of the diet, ketosis from the fat, and, to a small extent, from the protein. The diabetic may be described as an individual who utilises sugar too slowly; in the absence of carbohydrate more protein and fat are catabolised than normally and more aceto-acetic acid is produced; this acid is difficult to catabolise and is reduced to oxybutyric acid; the oxybutyric acid is excreted instead of being oxidised in the normal way. The work on which many of these categorical statements are based was done by HURTLEY.

Diabetes is therefore a general disorder of the metabolism; the patient cannot properly utilise carbohydrate, he produces carbohydrate from protein, and, further, he produces aceto-acetic acid from fat. It would follow that the rational treatment of diabetes is to curtail the amount of all kinds of foodstuffs to the lowest possible limit, so as to reduce the quantity of the excretory products. This is the modern treatment of the disease as described by Dr. E. P. POULTON in the Goulstonian lectures.[1] It has met with a considerable amount of success. Fatal cases in Guy's Hospital have been reduced from 23 per cent. in the ten years before 1916 to 7·7 per cent. since 1916, owing to the adoption of treatment by fasting. Similar results have been recorded in other hospitals. By the fasting treatment carbohydrate disappears from the urine, and there is less aceto-acetic acid. By careful addition of carbohydrate to the diet it is possible easily to determine the carbohydrate tolerance of the patient. He may be able to assimilate, say, 50 g. of carbohydrate, but not 100 g.; as soon as this is determined he is given the right amount in his diet. Similarly, the protein and the fat are adjusted. On these small diets the patient does not receive the caloric value of food which is considered necessary to maintain life. By careful treatment he may be made to take from 1500 to 2000 calories, the lowest limit for the normal individual. A considerably reduced amount of food has been shown to be capable of maintaining life without loss of efficiency.

Success has thus followed the application of the results of biochemical research, but the research on diabetes is not yet finished. It has depended on the chemistry of the proteins and the fats. Proteins have always been regarded as a source of both good and evil to mankind. The diabetic produces sugar from protein; yeast produces fusel oil; bacteria produce toxins. Proteins are indispensable for nutrition; there is no life without the amino-acid tryptophane; growth is dependent upon lysine; arginine and histidine are also essential to life, and they may be precursors of uric acid. In considering the protein moiety of the diet its quality is the most important factor. No two proteins are alike in their composition, just as outwardly eggs are not like meat; they are wrongly reckoned as alternatives in judging food values. Obscure points in other diseases have been cleared up by a knowledge of proteins, especially diseases of deranged metabolism. The biochemistry of fats, which is now in its beginning, is sure to throw more light upon normal metabolism and upon disease. The actual stages of oxidation of fat in the body are unknown, though much experimental work has been done. Minute biochemical research in the future will clear up this ignorance and abolish the numerous useless and unnecessary theories which impede progress rather than advance knowledge, since they simulate and are mistaken for facts.

[1] See THE LANCET, June 22nd and 29th, 1918, pp. 863 and 895 respectively, and the opening columns of the present issue.

The Medical Treatment of Elementary School Children.

THE Committee stage of Mr. HERBERT FISHER'S Education Bill was completed in the House of Commons on Wednesday, July 3rd. The Bill is in effect as much a Health Bill as an Education Bill, and when passed into law will very largely extend the health functions of the local education authorities. Some little time ago attention was drawn in these columns to the unfortunate omission in recent legislative enactments to provide for the care of crippled children, and the view was expressed that the urgency for provision for such children need only be brought to the notice of Mr. FISHER in order to secure the insertion in the Bill of a clause relating to them. It is gratifying to note that a new clause extending the provisions of the Education (Defective and Epileptic Children) Act, 1914, so as to apply to physically defective and to epileptic children was moved by Major HILLS and readily accepted by Mr. HERBERT LEWIS on behalf of Mr. FISHER.

An important discussion also took place upon the medical treatment of school children. The Education (Administrative Provisions) Act, 1907, placed upon all local education authorities the duty of providing for the medical inspection of children in the elementary schools, but, while empowering the authorities to provide medical treatment for those children needing it, imposed upon them no obligations in the latter respect. Mr. ROWNTREE proposed to include in the present Bill a clause making it obligatory upon the local authorities to provide treatment. Mr. FISHER, however, was in the first place indisposed to accept the new clause on the ground that the Board felt that they should leave the progress and development of medical treatment to voluntary action. He claimed that the progress already made justified that attitude. In support he quoted figures which showed that while in 1908 there were 55 local education authorities making arrangements for medical treatment, the number doing so in 1916 had risen to 216. A further consideration affecting the attitude of the Board was the difficulty of defining the particular ailments to be treated. Considerable pressure was in the course of the debate exercised upon the President of the Board to alter his decision, and eventually he undertook, in view of the large body of opinion in favour of Mr. ROWNTREE'S clause, to review the position and see whether he could bring forward on the report stage proposals which were watertight and administratively possible. As Mr. FISHER suggested, the exact definition of the limits within which the local education authorities must provide treatment will be no easy task. The remedial activities hitherto voluntarily undertaken to any extent have included refraction work, dental treatment, X ray treatment of ringworm, operations on tonsils and adenoids, and nursing treatment of the somewhat indefinite class of complaints which have been termed "minor ailments." Not all authorities undertaking treatment, of course, have covered the whole ground; there are, for instance, only 35 which provide operative treatment for tonsils and adenoids. Dental treatment, owing to the quite inadequate facilities which at present everywhere exist, will no doubt first claim the attention of the Board. Refraction work, owing to the importance of visual defect as an educational bar, will probably present no difficulty, as the Board have already indicated that refraction is to be looked upon as an extension of medical inspection rather than as treatment. Operations for tonsils and adenoids and X ray treatment for ringworm, however, will not be easy to decide upon.

The difficult question here arises as to parental responsibility. If the education authority must provide, must the parents also submit? The public treatment of minor ailments presents its own special difficulties owing to the possibility of encroachment upon the domain of private practice —a very important consideration and one which has already made itself heard in the discussions on the Bill in connexion with the extension to adolescents of the provisions for remedial care already enjoyed by the elementary school children. It will be seen, therefore, that the whole problem teems with difficulties, and Mr. FISHER'S hesitation in regard to it is readily understood. The results of his promised survey of the question will be awaited with some interest.

A National Scheme of Industrial Medical Research.

SIGHT should not be lost of a sentence in the final report (Cd. 9065. Price 2*s*.) on Industrial Health and Efficiency of the Health of Munition Workers Committee over which Sir GEORGE NEWMAN presides. In the Committee's view, the sentence runs, it is necessary to make arrangements without delay for a national scheme of industrial medical research, and to accord fuller recognition to the importance of industrial hygiene. It is now more than a century since the Health and Morals of Apprentices Act was passed, and the Committee disclaim the suggestion that the ideas embodied in their report are new and untried or in any way their own invention. A great national emergency gave them an opportunity of applying in a thorough way to munition work the knowledge of industrial hygiene of a century and of thus entering into other men's labours. But the report goes on to say that while the Committee fully recognise the debt owing to the great hygienic workers of the nineteenth century it remains true that up to 1914 little attention had been paid by employers and others responsible for industry to the steadily accumulating evidence of the influence of occupation upon health, and little effort had been made scientifically to investigate its causes. This neglect must now cease. The munition worker is a type of all workers, and the principles of the Committee's report concern all forms of industrial labour. There is imperative need for a firmer and more comprehensive grasp of the whole problem of health and physique in relation to industry. And to this grasp a national scheme of industrial medical research, combining all such powers as those granted in the Silicosis Bill just passed by the House of Commons, is an essential preliminary.

Annotations.

"Ne quid nimis."

THE PREVAILING PANDEMIC.

THE clinical features of the infectious febrile complaint which has invaded this country are sufficiently well known, and the following brief accounts by our Paris and Belfast correspondents suggest that they are dealing with the same malady.

Paris.—A widespread epidemic of *grippe* in a mild form is at present invading Paris and a large part of France. It is probably an extension of the epidemic which has recently attacked the whole population of Spain, from the highest to the lowest. The cases are very numerous, but none so far of a grave nature. Complaint is made of headache, pain in the back, naso-pharyngeal catarrh which is persistent but rarely invades the lower respiratory tract. The temperature is moderately raised, dropping at the end of two days. The resulting indisposition, which seems to be spreading to the troops at the front, fortunately lasts at most a few days.

Belfast.—An extremely widespread epidemic of what is called "influenza" is prevalent in Belfast and surrounding districts. The number of deaths in Belfast for the week ending June 29th was 341, and of these 92 were from "pneumonia" and 75 from "other diseases of the respiratory system." It began apparently in the military barracks at first, but soon spread to munition works, mills, &c., and thence all over the city and surrounding areas. The symptoms are mainly high temperature with a sudden onset, congested eyes, sore-throat, and headache, with muscular pains, and in uncomplicated cases the duration of the fever is about three days. Occasionally there are sickness and bronchial catarrh, but pneumonia is not common. It resembles influenza in its sudden onset and its widespread epidemic character, but differs from former visitations of that disease in comparative absence of chest complications and post-febrile depression. The locus of the disease seems to lie in the throat, at the junction of pharynx and larynx. Bacteriological examination so far has shown the presence of diplococci, streptococci, and pneumococci, but no specific organism. It is being recommended to close the primary schools—a measure as little likely to be effective as shutting down the banks, mills, munition works, and cinemas. The epidemic seems very like the Spanish one recently reported.

The paper by Captain T. R. Little, Captain C. J. Garofalo, and Captain P. A. Williams, of the Canadian Army Medical Corps, which appears in another part of our present issue, is the first serious contribution which we have seen to the bacteriological study of the pandemic. These authors deal with about 1000 cases occurring in several camps served by their mobile laboratory. After setting out three points in which the clinical symptoms differed from those generally ascribed to Pfeiffer's bacillus, the statement is made that in all the cases studied one organism predominated in direct smears taken from naso-pharynx, throat, and sputum. This was a small Gram-positive diplococcus, flattened on its opposing surfaces. It was found to grow freely on legumin serum-agar plates, forming small transparent granular colonies closely resembling those of streptococcus. No colonies of *B. influenzæ* were discovered. The authors are now working to establish Koch's third postulate in relation to the organism. It is noteworthy that Dr. A. MacLean, who contributes to this present issue a memorandum on an outbreak of an acute febrile disease in certain Glasgow factories, has also found a diplococcus, in this case Gram-negative, in association with it. The disease, of which he dealt with 436 cases, was of a very mild type, characterised by sudden onset with severe headache and prostration, followed by rapid recovery in 2–4 days. No death was recorded, but a similar outbreak was brought to his notice in the county of Lanark, in which 8 deaths occurred in 280 cases. Acting under Dr. A. K. Chalmers, medical officer of health for Glasgow, Dr. MacLean is studying further the bacteriology of the outbreak. We commend both these series of investigations to the attention of bacteriologists in general. The loose application of the term "influenza" to a febrile infection in which Pfeiffer's bacillus cannot be demonstrated is, to say the least, unfortunate and we have always deprecated its use, suggesting as an alternative the term "catarrhal fever."[1] Mild though the present form of the malady is in a vast majority of cases, its death-rate has not been insignificant, and its epidemiology is a matter of very pressing importance.

ECGONINE AND ITS DERIVATIVES.

THE Home Secretary has given notice that the definition of "cocaine" in Defence of the Realm Regulation 40 B (which regulates dealings in cocaine and opium) and in the Proclamation prohibiting the importation of cocaine has been further amended so as to include ecgonine, its salts and derivatives. The definition now reads as follows:—

"Cocaine includes ecgonine and any substance, whether preparation, admixture, extract or otherwise, containing 0·1 per cent. (one part in a thousand) or more of cocaine or ecgonine or of any salt or derivative thereof."

Ecgonine is the parent of cocaine, which is benzoyl-ecgonine methyl ester. There are many other derivatives of ecgonine in the leaves of *Erythroxylon coca*, from all of which ecgonine can be separated. Cocaine is obtained economically from ecgonine by a synthetic process, using methyl alcohol and benzoyl chloride. Ecgonine is the essential pharmacological group of the alkaloid.

THE DEVELOPMENT OF THE MEDICAL PROFESSION: THE CAVENDISH LECTURE.

Major-General Sir Bertrand Dawson, in delivering the Cavendish lecture this year before the West London Medico-Chirurgical Society, found that the subject which he had selected could not be intelligibly expounded within the compass of one lecture, with the result that on Thursday evening he continued at the Royal Society of Medicine his Utopian picture of the future of the medical profession in this country. At the West London Hospital, where he had a large audience, he made the following point in an incontrovertible manner—that the growth of knowledge had rendered medical effort, whether for treatment or prevention, a combination of energies. No man any longer can pretend to have particular equipment or special knowledge by which he can do the best possible for all patients in all circumstances. There must in every case be some point where the special knowledge not possessed by any particular doctor might have been useful, and we shall all endorse Sir Bertrand Dawson's plea for the development of "team-work" in medical practice. The need for adequate medical service has outstepped its provision not only for the masses but for the well-to-do, added Sir Bertrand Dawson, who prophesied that the unsuitability of the home for the treatment of the sick would soon become generally recognised when larger institutional organisation would follow as a sequel. Reconstruction of medical practice on these principles, with the general practitioner the central pillar of erection, implies that the general practitioner must have opportunities for observation, advanced education, and prosecution of research which he is now totally without, but, as the Cavendish lecturer acutely pointed out, he requires, if he is to get any advantage out of such improvement in his professional life, adequate repose and adequate

[1] THE LANCET, 1910, ii., 1289.

remuneration. The medical service which Sir Bertrand Dawson outlined would have the local hospitals and clinics as their centre, and the staff of the central hospital would provide the consultants and specialists for the local hospitals, and would be a whole-time or part-time service according to the nature of the work. He dwelt upon the complications of working such an organisation alongside of the National Insurance Act, whose administration of medical benefits is directed towards the treatment of disease rather than its prevention. In the sequel, a second part of the Cavendish lecture delivered on Thursday night, the lecturer supplied the arguments to show that the officiate of the Ministry of Health should be in its essential characters medical, and the profession at a critical time in its career will be grateful to him for an outspoken pronouncement.

ANTINEURITIC AND ANTISCORBUTIC FACTORS IN FOOD.

Two interesting papers on the obscure but important constituents of foods known respectively as antineuritic and antiscorbutic substances appear in the June number of the *Bio-Chemical Journal*. The first is by Mr. J. C. Drummond, which embodies a study of the water-soluble accessory growth-promoting substance and its influence upon the nutrition and nitrogen metabolism of the rat. In this research, carried out in the Cancer Hospital Research Institute, London, the author found that the only apparent deviation from normal health in rats fed upon an artificial diet deficient in the water-soluble accessory substance was the appearance of creatinuria accompanied by a slow wasting of the skeletal muscles. The food consumption of rats fed upon the deficient diet is low, being probably reduced to that amount sufficient to supply the calorific requirements of maintenance. An increased food consumption is brought about by the addition of flavouring agents such as meat extract to the diet, but it is interesting to add that unless this agent contains the water-soluble substance no growth results. This observation seems to supply a criterion as to the value of meat extracts in the dietary, and those deficient in the accessory substance might have to be ruled out as possessing any dietetic value. The addition to the inadequate diet of water-soluble substance causes a greatly increased food intake, immediately followed by growth, the amount of growth being, within certain limits, proportional to the amount of accessory substance added provided that the diet is adequate in other respects. The experiments bear evidence that the length of time an animal is able to maintain itself upon a diet deficient in the water-soluble substance without suffering a serious loss of body-weight is directly proportional to the age at which the restriction is imposed. During the research it was found that actively growing animal tissues (embryos, tumours) do not contain appreciable amounts of the "water-soluble B" and pituitary gland, thyroid, thymus, testicle, and ovarian tissues showed a deficiency in this substance. The results are of interest, although the cause of the fatal decline which inevitably follows a deficiency of the water-soluble substance has not been determined. It may be noted, however, that symptoms of nerve disorder preceded death in three cases. In the second paper Arthur Harden and Sylvester S. Zilva deal with the differential behaviour of the antineuritic and antiscorbutic factors towards adsorbents. This research was undertaken in the Biochemical Department of the Lister Institute. The authors have confirmed the fact that fuller's earth absorbs almost quantitatively the antineuritic factor out of autolysed yeast. Dialysed iron does the same thing, but neither fuller's earth nor dialysed iron affects appreciably the antiscorbutic potency of orange juice, so that in a fluid containing autolysed yeast and orange juice the antineuritic factor is removed, while the antiscorbutic activity remains unimpaired. These observations are of interest in showing that there is nothing in common, apparently, between these antineuritic and antiscorbutic substances respectively so far as regards their behaviour with adsorbents. It is early yet to lay down what physiological significance these observations possess.

INCIDENCE OF INFECTIOUS DISEASE IN 1917.

Sir Arthur Newsholme's report to the Local Government Board on the local incidence of notifiable infectious disease has recently been published, the present being the seventh of the series.

Notifications in England and Wales during 1917.—Only 7 cases of small-pox were reported in the year, the average number in the preceding six years being 139. Typhus fever was reported in 4 cases only, against an average of 30. Of scarlet fever 48,817 cases were notified, or fewer by 26,905 than in the preceding year. Of diphtheria 43,315 cases, or 8392 fewer; of enteric fever 4601 cases, or 963 fewer; and of puerperal fever 1345 cases, or 651 fewer. The only diseases known to have shown increased prevalence in 1917 were cerebro-spinal fever and pulmonary tuberculosis, the reported cases of the former having increased to 1465, against an average of 1123 in the previous four years, and the cases of the latter having numbered 73,654, or more by 1175 than those notified in 1916. But this number includes duplicate notifications. The cases of measles notified under the Order of 1915, by medical men or by persons in charge of patients, exceeded half a million, but in this total German measles is included. In addition to the foregoing there were notified in England and Wales 13,325 cases of erysipelas, 357 of poliomyelitis, 8 of plague, and 6716 of ophthalmia neonatorum.

Seasonal incidence.—With respect to the seasonal incidence of scarlet fever, diphtheria, enteric fever, cerebro-spinal fever, poliomyelitis, and measles particulars are given in a table—the actual average weekly attacks being shown at the foot of each column. The proportion of the notifications to this average is given for each week, any special seasonal excess of 30 per cent. being indicated by heavy type.

Cases of sickness among sailors and soldiers.—Under a recent Act local medical officers of health now receive notification of all cases of infectious disease arising in barracks, camps, &c., in the occupation of H.M. Forces. The number thus reported in 1917 include 1244 of scarlet fever, 1296 of diphtheria, 177 of enteric fever, 442 of erysipelas, 2 of small-pox, 1023 of cerebro-spinal fever, 2210 of pulmonary tuberculosis, and 122 of other forms of tuberculosis.

In proportion as it becomes possible to compare the behaviour of infection in a longer series of years the value of these reports will obviously increase.

THE TREATMENT OF SCIATICA BY LUMBAR ANÆSTHESIA.

THE strenuous life of troops in the trenches and the exceptional climatic conditions of damp and cold have been productive of a large number of severe and refractory cases of sciatica and allied conditions in the military hospitals in Italy. In addition to these rheumatic cases there have been many others due to the direct action—contusion or wound of the nerve, or indirect action—neuritis following septic wounds, of projectiles. A large number of such cases have come under the notice of Dr. Claudio Mancini[1] at the military hospital at Spezia, who has obtained very encouraging results from treatment by lumbar anæsthesia, which may be summarised as follows.

[1] La Riforma Medica, June 1st, 1918.

Attempts have been made in the past to act directly on the sciatic nerve by injecting its trunk with anæsthetic solutions, thus Lange practised perineural infiltration with physiological solution, with the addition of tropococaine and stovaine at a temperature of 37°-38° C. Jaboulay proposed the injection of anæsthetic solution into the retro-rectal space in front of the coccyx with the idea of acting on the sacral sympathetic, and Cathelin and Sicard with the same intention made the injection into the epidural space. This latter method, however, is not easy of execution in fat subjects, and its action is uncertain and limited. Dr. Mancini's method proposes to obviate these inconveniences and carry the anæsthetic into contact with the roots of the injured nerves and their medullary connexions by lumbar puncture. For some years he used the ordinary mixture of novocaine and stovaine, but he now uses the former alone in doses of 12-15 cg. in a 5 per cent. solution. The injection is made in the third or fourth intervertebral lumbar space, and the duration of the anæsthesia varies from three-quarters of an hour to two hours. Note that novocaine undergoes changes by prolonged boiling or in old solutions, so that it is preferable to prepare the solution at the moment of use by dissolving the requisite quantity of novocaine in distilled water, previously sterilised and cooled, in a sterile test-tube, bringing it to the boil two or three times and rapidly cooling under a tap.

In traumatic cases which are susceptible to the anæsthetic action there must necessarily be an absence of anatomical lesions, such as cicatrices, adhesions, and compression. A prominent fact, however, was that in cases where spastic paralysis existed only to a small extent a permanent disappearance of pain and spasm followed the treatment. On the other hand, where the pain was merely symptomatic, as in incipient tabes, tuberculous coxitis, or Pott's disease, lumbar anæsthesia failed entirely.

THE PRIMARY CAUSE OF SHOCK.

IN an article published under this title in the *Medical Record* for June 2nd Dr. Fenton B. Turck has summarised his extensive observations on surgical shock, and has put forward a novel theory as to its causation. The starting point of the author's theory is his belief that injured tissue at once begins to undergo self-digestion, leading to the production of toxic albumins which when absorbed are deadly poisons. He finds that the stomach, intestines, and liver are the organs most severely affected by these "shock poisons," and that the nervous system is not primarily involved in shock. The possibility of producing immunity against shock forms a natural development of this conception, and the author holds that a high degree of immunity can be induced by injecting into an animal repeated and increasing doses of the homologous autolysed tissue. In the course of his experimental study of shock, Dr. Turck found that the intravenous injection of peptones brought about a condition of shock similar to that following on severe wounds or mechanical injury to the tissues; the same condition was produced by the injection of autolysed muscular tissue. In one series of experiments Dr. Turck shut off a limb by elastic ligatures from the general circulation and then mechanically injured the muscles peripheral to the ligature, thereby "liberating and disintegrating cells" and permitting autolysis to occur. After a variable interval the elastic ligature was removed and the free autolysed cells and their products were allowed to enter the general circulation; this procedure promptly caused severe symptoms of shock. Shock also occurred if the autolysed muscle tissue was transplanted into another animal or if the extract of such tissue was injected into another animal. Dr. Turck's work on the possibility of producing in man immunity against wound shock is still in progress, and obviously many difficulties have to be got over before the conclusions are accepted.

TECHNICAL RE-EDUCATION IN ITALY.[1]

BY PROFESSOR ETTORE LEVI (FLORENCE),

MEMBER OF THE EXECUTIVE COMMITTEE OF THE ITALIAN NATIONAL COMMISSION FOR THE ASSISTANCE AND PROTECTION OF THE DISABLED.

A LAW for the protection and assistance of men disabled in the war was adopted by the Italian Parliament in March, 1917, and upon it is based the whole complex work of the after-care and social assistance of the disabled man, whether incapacitated by wounds or illness.

The execution of this great undertaking was entrusted to a new organisation, known as the National Commission for the Protection and Assistance of the Disabled, composed of Members of Parliament, administrators, specialists, and disabled soldiers themselves, presided over by Professor Durante, Senator.

Organisation of Treatment.

The amalgamation of existing civil and military organisations was brought about of necessity, by the experience of the first year of war. For this experience showed that re-education, as a general measure, was doomed to failure if it were not preceded by adequate moral and physical preparation of the disabled man from the initial stages of his incapacity, and followed by a wise and kindly supervision during the critical period of his return to normal surroundings. Ideally, this pre-re-education—that is to say, the moral preparation of the patient—should be initiated at the very moment when he first realises that he will remain hampered for life by his physical disabilities.

In order to realise such an ideal we have attempted in Italy to concentrate without delay all the seriously disabled in two surgical first receiving centres, where they may live in an atmosphere favourable to their preparation for an active future. For this reason every patient, from whatever sector of our extended front he may come, is immediately conveyed to Mantua for the Northern front and Bari for the Eastern front, where he is ensured efficient treatment and intelligent moral preparation.

In order to carry out such preparation from the start—in field hospitals and hospital trains—the National Commission undertook the distribution of a pamphlet designed to popularise the law relating to the disabled, explaining to the patient and to all who may attend him—doctors, nurses, chaplains, and so on—what are the rights to which he is entitled and all that these imply: medical and surgical attendance, free provision of artificial limbs, maintenance for six months in a school of re-education, the laws relating to pensions and legal medical attendance, social relief and the securing of employment. This pamphlet has served the purpose of explaining to many discharged disabled soldiers the rights and privileges which were not at first made adequately clear to them.

From the first receiving hospitals in Mantua and Bari, the patients are distributed among the first-grade concentration hospitals of Turin, Milan, Genoa, Bologna, Florence, Rome, and Naples, and thus brought without delay into the neighbourhood of their families and of their normal environment. Surgical treatment is completed under healthy and agreeable surroundings, and the moral preparation, already initiated, carried on by the personnel of the local School of Re-education. As soon as the patient is able to sit up in bed he is encouraged to attempt light occupations, such as bead-work, cardboard-work, and toy-making. Thus his passive mentality is transformed into an active mentality, and he begins to feel the hope of a renewed possibility of work and to appreciate its necessity.

When his wounds are nearly healed he passes to the local concentration hospital of the second grade, where his physical and orthopædic treatment is completed. Mutilated limbs are adapted to artificial members, and crippled limbs are functionally restored as far as possible. The patient is no longer confined to bed and is encouraged to attend the existing schools. Here the illiterates, unfortunately numerous in Italy, are taught to read and write; or, having already mastered the rudiments of education, they may bring their knowledge to some degree of perfection. Small workshops are provided for the light manual work suitable

[1] Abstract of a Paper read at the Inter-Allied Conference on the After-care of Disabled Men.

to the great mass of disabled men who come from agricultural districts; these deal with wicker-work and basketry, coopering, clog-making, and the like. By these means even patients who refuse to spend six months in the schools of re-education are enabled to return to their homes with some notion of exercising their normal occupations. During this period they are furnished with temporary artificial limbs.

Schools of Re-education.

Then follows the third and last period of treatment. The physical treatment of the patient completed, after a month's leave he passes on to the School of Re-education already existing in each one of the above-mentioned cities. Re-education is, unfortunately, not compulsory in Italy, but the law makes it compulsory for every indigent patient to stay at least 15 days in the schools of re-education. He is, accordingly, made to realise the possibilities open to him and does not risk refusing such benefits owing to an incomplete appreciation of them. The return of those who repent of their refusal is thus made easy. Only in the School of Re-education itself do the disabled men receive their permanent artificial limbs. These are supplied by the special laboratory attached to each school under the direction of an orthopædic surgeon. Many schools also furnish gratuitously the necessary implements for the exercise of the trades and handicrafts taught there. This system has the object of centralising and retaining every patient for the longest possible time in the schools of re-education.

These schools were established in Italy through local initiative, and for this reason neither their administration nor their programmes have been perfected or coördinated. They are now, however, under the control of the National Commission, which will reinforce and organise them according to a general and uniform design, as follows:—

1. The great mass of disabled agricultural workers will be given some elementary scholastic knowledge.
2. They will be taught at least one of the easier trades which may be followed in any part of the country, and are known therefore as subsidiary to agriculture.
3. The more informed and intelligent agricultural labourer will receive instead a general and technical instruction which shall advance him according to his former occupation, teaching him the more highly specialised methods of agriculture and of stock-breeding. Such a programme will tend to check the artificial movement toward the cities and the pernicious pursuit of Government employment.
4. Disabled men who prefer non-agricultural work will find in the same centres of re-education both primary and secondary schools and workshops where they may be trained in the trade most adapted to their education, with special reference to local industries.

We in Italy are convinced that the resident system is greatly superior to the non-resident, and we have, therefore, put the former into more extensive practice, yet without such rigid enforcement as to prevent men availing themselves of every practical local training scheme carried out upon a different basis. We are equally convinced that the larger institutions present material advantages over the smaller. Up to the present time, however, the smaller institutions have perforce been more prevalent with us, since, during the early days of private initiative in Italy the local bodies, though zealous, were little controlled and lacking in means. The National Commission, now reviewing the entire situation with impartial judgment, intends to give the maximum of assistance to the more flourishing institutions, and inexorably to condemn the weaker and less successful. The work of supervision and control is carried out by continuous inspections, entrusted to committees chosen from among the members of the National Commission, and composed for the most part of a specialist in re-education, an administrator, and a disabled officer or soldier.

In this regard it is worthy of note that there exists in Italy a flourishing Association of Disabled Soldiers, numbering already some 20,000 members, and acting in strict accord with the military authorities and with the National Commission. Representatives of this society are members of the Council of the National Commission and of every local committee. They have also the right to control the methods of re-education prevailing in the various centres. The National Commission exercises its complex work of control through the medium of the local committees, which during the first period of the war spontaneously undertook the establishment of schools of re-education. The local distribution of these institutions is, however, unfortunate, being numerous in the north and scarce in the south. To obviate this grave inconvenience the National Commission is undertaking, at its own expense, to found a large institution at Bari, and another in Sardinia, and is intending also greatly to extend the already existing institution at Naples.

Other Details of the Scheme.

The National Commission is actively engaged in the preparation of a new and complete census of the disabled men who have already returned to their homes. The Commission will thus be enabled to supply, with the least possible delay, what has been lacking in the past. For only by means of an exact report of the physical, re-educative, and social circumstances of each individual is it possible to bring under fresh supervision those disabled men whose condition is still capable of improvement, to complete and perfect the application of artificial limbs, to attract to the schools of re-education those who have not already profited by them, and to secure employment for those who have or have not been re-educated.

The Commission is also organising a Special Committee for the Study of Prosthesis, endowed with ample powers and an extended programme. This committee will study, both from a practical and scientific standpoint, the subject of artificial limbs in general, and of those adapted for industrial purposes in particular.

For the treatment and re-education of the blind the same general scheme will serve. From Mantua and Bari they are rapidly centralised in the ophthalmic first concentration hospitals of Milan, Rome, Florence, Naples, and Catania. The same general plan is followed for the permanently deaf-mute, who will be taught lip-reading in special institutes.

The disabled of every grade receive free maintenance in the schools of re-education for a period of six months, which may be extended in the case of those who show themselves deserving. The financial requirements of the National Commission are determined year by year by the Ministry of the Interior, acting in collaboration with the Council of the National Commission. The finances of the schools of re-education, previously supported by private funds, will be taken over by the Commission, as is necessary or desirable. The Commission undertakes also to administer gifts or legacies made to the disabled.

Lastly, the National Commission has also the task of extending its protection and assistance to all service men incapacitated through illness. This is a work of immense proportions and of essentially medical character, which, however, must not be separated from re-education. For no patient, until he be restored to favourable physical condition, is capable either of re-education or of social usefulness. Special study is being given by the Commission to the grave problem of the tuberculous cases, with the close coöperation of the military and civil sanitary authorities. It is intended that tuberculous patients shall be taught, in special tuberculosis sanatoria, that régime of life which they must follow if they hope to be cured. While actively forwarding such antitubercular pre-education the Commission expects to have among such patients a steadily increasing percentage who may become candidates for a future technical re-education, under a special supervision which must never lose sight of the pathological origin of their disability.

The financial and industrial future of all disabled men in Italy is facilitated by the fact that the foresight of the law has undertaken to insure them against industrial accidents, and will also advance to them, with the guarantee of their pensions, sufficient loans to make possible the building of farmhouses or the purchase of cultivable lands. The concession of such benefits is under the strict control of the National Commission, which will, however, give it the widest possible application, so that in time a large proportion of our disabled agricultural workers will become proprietors of small farms which they may cultivate by their own labour.

Those who desire fuller information upon the subjects treated in the foregoing report may refer either personally to Professor Ettore Levi, Piazza Savonarola 11, Florence, Italy; or to Opera Nazionale per la Protezione ed Assistenza degli Invalida di Guerra, Palazzo Taverna, Via Monte Giordano, Rome, Italy.

DRIED MILK FOR INFANTS.

THE Local Government Board has issued for wide circulation the following résumé[1] of Dr. F. J. H. Coutts's report on Dried Milks, with Special Reference to their Use in Infant Feeding. The conclusions of the report are based on an average of 26 samples of full cream dried milk examined at the Government Laboratory, and the report refers in several places to the previous food reports, No. 15 and No. 20, dealing respectively with condensed milks and proprietary foods for infant feeding.

Dried milk or milk powder is a substance prepared from cows' milk by the abstraction of almost the whole of the water so as to leave practically nothing but the solids of the milk. The product may contain varying amounts of milk fat, according as it is made from full cream milk or from milk partially or completely skimmed. Dried milk made from full cream milk contains 26·62 per cent. of fat, 24·46 per cent. of protein, 36·98 per cent. of milk sugar, 6·12 per cent. of mineral matter, and 4·32 per cent. of water.

There are several processes for preparing dried milk, but two methods are most commonly employed: (*a*) by passing liquid milk over metal cylinders heated internally by steam or hot water; and (*b*) by spraying milk, after partial condensation, into heated air. The chief object is to obtain milk in a solid condition with as little change as possible in the milk constituents.

Dried milk is a light yellowish-white powder which, when carefully prepared from good fresh milk, keeps for several weeks or months if it is kept dry. On mixing with warm water in the proportion of 1 part by weight of the dry powder to 7 parts by weight of water (approximately one large teaspoonful of the dried milk to two tablespoonfuls of water) a liquid is obtained corresponding in composition to ordinary milk, but usually having a slight boiled taste and a tendency for a little solid matter to settle and for fat to rise to the top.

Dried milk as put on sale in this country comes usually under one of four classes: (1) Full cream; (2) three-quarter cream; (3) half cream; and (4) skimmed. Full cream dried milk for baby feeding is sometimes sold merely under this description, but certain firms supply it under special names or brands.

It is most important to emphasise that babies should, wherever possible, be fed solely on their mothers' milk.

If this is impossible it is best to feed partly on the breast and partly on the bottle. No other food can really replace breast milk. If, however, an infant must be hand-fed, cows' milk in some form or other is the most satisfactory substitute usually available.

Dried milk for feeding of infants.—Experience during the last 12 or 14 years shows that dried milk is one of the most satisfactory forms of cows' milk for use in the feeding of infants. It has been very largely employed in connexion with infant welfare centres in England, particularly in Leicester and in Sheffield, and experience in these towns, and also in many other places, shows that a very large proportion of babies can take dried milk very well, and that on this food they thrive and develop in a satisfactory manner. It has been found that babies digest dried milk well. Vomiting is less frequent with dried milk than with ordinary cows' milk.

Fresh, clean, pure, raw cows' milk is a very good food for a baby when mothers' milk is not available, but unfortunately the milk ordinarily sold in towns does not conform to this description, being often far from clean and containing large numbers of germs. Such milk, especially in summer, will not keep a day without becoming sour and is apt to cause digestive troubles in babies. Dried milk contains far fewer germs than ordinary town milk, and is less likely to contain the germs of infectious diseases. Also germs do not multiply in dried milk; they do in ordinary milk. Dried milk keeps well so long as it is kept dry. Only as much should be made up at a time as is required for one feed, and there need, therefore, be no waste. Pasteurised, sterilised, or boiled cows' milk are useful foods if properly prepared, but they have some disadvantages as compared with dried milk. In particular, they do not keep well, especially in summer.

Unsweetened full cream condensed milk is also useful for baby feeding, but when mixed with water in the proportions sometimes recommended it is too weak for the satisfactory nourishment of the baby. *Sweetened* condensed milk is often used for baby feeding. Dried milk has the advantage, when made up with the proper proportion of water, of containing the essential food elements in a proportion more suitable for the baby than when full cream sweetened condensed milk is used. The latter, if made up so as to give the right proportion of fat, has a very excessive amount of sugar. This is not good for the baby, who usually becomes fat and flabby, and is liable to suffer from diseases such as rickets, &c. These same risks attach to other infant foods containing excess of sugar.

So-called "malted" milks have in recent years been recommended for baby feeding. These, like sweetened condensed milks, contain much too low a proportion of fat as compared with the amount of sugar. They differ from sweetened condensed milk in the nature of the sugar. In condensed milk this is mainly cane sugar, in malted milk it is largely malt sugar derived from the malted cereal used in its preparation. The ordinary patent infants' foods, containing large quantities of practically unaltered starch, are worse than sweetened condensed milk or malted milk. They are not fit for use for a baby under seven months of age.

In view of the above considerations it is not surprising that at official infant welfare clinics dried milk is becoming used to an increasing extent as on the whole the most convenient and most suitable food when babies cannot get breast milk. In feeding babies on dried milk the *full cream variety* should alone be used, unless on the advice of a doctor. Commencing with 1 teaspoonful of dried milk in 3 tablespoonfuls of water in the first or second weeks of life, it can be rapidly increased to 1½ to 2 teaspoonfuls of dried milk in 4 to 5 tablespoonfuls of water by the end of the second month, and so on to 5 teaspoonfuls of dried milk in 10 tablespoonfuls of water at the age of 5 or 6 months.

Fears were at one time expressed that the use of dried milk for babies might result in scurvy or rickets. Prolonged experience at infant welfare centres has indicated no ground for these fears; but as an extra precaution to avoid the possibility of scurvy, and particularly if the use of dried milk is to be continued for a long time, a little fruit juice, such as orange or grape juice, may be given to the baby one or twice a week.

Dried milk is also a valuable food for nursing mothers.

In a very large number of towns dried milk for baby feeding is supplied from infant welfare centres, at which advice is also given as to the method of preparing and using the food. Where any difficulty is experienced in obtaining supplies of dried milk for infant feeding information can be obtained by application to the medical officer of health.

We have already referred briefly[2] to the report on dried milk for infants in which Dr. Coutts concluded that, while the method of drying by spraying milk into hot dry air yielded a powder which "reconstituted" better than the powder obtained by the roller process, yet in infant feeding there appeared to be no dietetic difference of importance between the two products.

"Audi alteram partem."

JURIES AND WAR-TIME CHANGES.

To the Editor of THE LANCET.

SIR,—The annotation on this subject in your issue of June 29th is a timely one because of the necessity of upholding the standard of liberty in this country. The coroner's court is in constitution and practice entirely democratic, and it appears strange that at a time when Democracy (spelt with a very large D) is more and more obtaining power and influence in legislation it should be quite content to deliver up without a murmur its most ancient and honourable court. The removal of liberty from the citizens of this country is in the air, and the interference with the coroner's court is one of the many signs of what is in store for us.

I agree substantially with Dr. Waldo's reluctance to sit without a jury as coroner, and it appears to me that the only change which is in any way desirable is that the coroner should have the power to hold inquests without a jury when he thinks fit. There is no doubt that if any coroner seriously abused this discretion public opinion would very speedily correct him.

A recent decision in the High Court has made the legal position of proceedings in coroners' courts quite clear. The coroner's court is one of first instance, and its function is to determine how, when, and where a person has come to his or her death. It is work, therefore, principally concerned with medical evidence, and consequently legal knowledge is as unnecessary as common-sense and knowledge of disease or injuries are necessary. It has become the fashion to suppose that the passing of examinations for the position of barrister-at-law as well as a medical qualification are of importance for the holder of the coroner's office; there really is no ground for this fashion, the presumption being that a man who is a barrister-at-law and a registered medical practitioner has not been a success in either profession.

I am, Sir, yours faithfully,

Hatfield, July 1st, 1918. LOVELL DRAGE.

"SEXUAL PERVERSION."

To the Editor of THE LANCET.

SIR,—In your issue of June 22nd Dr. L. Weatherly writes of "Sexual Perversion," attributing it to several causes. Though I think all these are more or less open to criticism I will confine my remarks to that one only which he names "inherited perversion," for it plays the most prominent part among the five classes he enumerates, and the implications of this very indefinite term were made use of in the late libel action to which Dr. Weatherly refers.

Though Dr. Weatherly does not define what he means by "inherited perversion," or, indeed, by the word "perversion" itself, it may, I think, be assumed that he denotes by sexual perversion any manifestation of sexual excitement, desire for sexual contact, or actual sexual contact with a person of similar sex, or, in other words, homo-sexual tendencies in either sex. And when he attributes such tendencies to "inheritance," he probably regards them both as pathological, "inborn," and transmitted as such. There is, however, a large class of cases in early youth and adolescence in which, as is well known to many, if not most, medical men, such manifestations *exist*, but do not *persist* when rightly guided by experience and education in the widest sense of these words. That such cases are not uncommon is also known to many parents and teachers, and they are quite frequent in schools of all kinds. Dr. Weatherly, however, does not lay any stress on these youthful cases, though they far outnumber the adult cases to which he limits his comments. It is surely more correct to attribute these manifestations rather to a natural, unrecognised, undifferentiated, and unguided sexual instinct than to a naturally abnormal and necessarily perverted instinct. In a majority of such cases *right guidance* of these instincts, all too much neglected by those who have it in their power to give such guidance, would either prevent or readily correct such indulgences on the part of the young, who are really ignorant of the nature of the desires which move them. The young human must not only *learn* to walk and to speak, but he must also *learn* nearly all that concerns his conduct as a civilised human being. He has not so many instincts as many of the lower animals have, but he has very early to learn to control his promiscuous desire for food and his natural curiosity and his tendency to appropriate or destroy what is not his. His sexual instincts, developing later than these other instincts, nevertheless equally require guidance, but very often, perhaps most often, they are allowed to develop without any proper "direction," and thus he runs the risk of bearing the blame, or the disgrace, or the punishment which is meted out to those who transgress the social rules, whether wittingly or not, in this special sphere of conduct.

It is the young, not the adults, which matter most in any discussion of this subject. Misunderstanding here may lead, and has led, to disastrous results. In schools such misconduct is not, as a rule, warned against or prevented, but when a scandal is feared it is severely punished. But there is another evil possibility from the spread of the comprehensive doctrine of "inherited perversion," apart from its hypothetical nature. For it may lead to the provision of excuses to those who certainly cannot plead ignorance for conduct to which penal coercion may be more fitting.

I am, Sir, yours faithfully,

June 29th, 1918. H. BRYAN DONKIN.

METHODS OF GENERAL ANÆSTHESIA IN FACIAL SURGERY.

To the Editor of THE LANCET.

SIR,—I am glad that Captain T. Lovett has drawn attention in THE LANCET of June 22nd to the advantages of a preliminary opening of the air-tube in some of these cases, but I would point out that for such purposes laryngotomy is, as a rule, preferable to tracheotomy. As shown in articles by Dr. J. W. Bond and the late Sir Henry Butlin, by the former operation dangers of aspiration of blood from the wound and of opening up the deeper tissues are avoided—and it may be done very quickly and easily in the way therein described. If there is no need to keep the tube in after the operation the wound will speedily heal if the head is kept bent forward. It may be added that when chloroform is given from a Junker's tube held near the opening very little is needed, especially if care is taken to time the compressions of the ball to the inspirations.

I am, Sir, yours faithfully,

London, N.W., June 24th, 1918. J. D. MORTIMER.

To the Editor of THE LANCET.

SIR,—With reference to Captain T. Lovett's letter in THE LANCET of June 22nd, I should like to say that we have, in a few cases, employed preliminary laryngotomy, after induction of anæsthesia, as used by the late Sir Henry Butlin, consulting surgeon to St. Bartholomew's Hospital, and handed down through Mr. W. D. Harmer to Major Gillies, and I think that this method is preferable to tracheotomy. I quite agree that it is very useful when there is much oral sepsis, but we rarely employ it, and we have very few cases of pneumonia. This may be due to our healthy surroundings.

I am greatly indebted to Captain H. E. G. Boyle, R.A.M.C. (T.), for his kindness in demonstrating to me the technique of oil-ether administration, and also to Major Gillies, R.A.M.C., for his great patience and watchful help during operations.—I am, Sir, yours faithfully,

R. WADE, Captain, R.A.M.C.,

July 1st, 1918. Anæsthetist, The Queen's Hospital, Sidcup.

THE RISKS OF ALCOHOL INJECTION FOR TRIGEMINAL NEURALGIA.

To the Editor of THE LANCET.

SIR,—Professor Jonathan Hutchinson, in his lecture on the Operative Treatment of Trigeminal Neuralgia in to-day's issue of THE LANCET, mentions the eye complication only which may result from alcohol injection. I should like to record that I have seen two cases lately in which the middle ear has been badly and permanently disorganised owing apparently to the spirit entering the Eustachian tube.

I am, Sir, yours faithfully,

Savile-row, W., July 6th, 1918. ARTHUR H. CHEATLE.

SIMILAR TREATMENT FOR SIMILAR EMPLOY.

To the Editor of THE LANCET.

SIR,—The answer given by Mr. Forster to Sir Robert Newman in the House of Commons on July 2nd seems a little misleading. He said: "These women doctors serving for home duty only, on temporary engagement, are treated in the same way as civilian medical men similarly employed." Now, there are women doctors attached to military hospitals at home on a month's engagement who receive 24*s.* a day, as against £1 paid to the whole-time medical man. I know one of the latter, over military age, who has had 17 years' experience of X ray work, and during the first two years of the war was giving anæsthetics daily in a civil hospital. He was invited to take the post of combined anæsthetic and X ray specialist in a war hospital, and was offered £1 a day as a whole-time civilian. He took the appointment and, having agreed to that very moderate remuneration, did not consider it fitting to have a question on the subject asked in the House.

Many women doctors engaged by the War Office have only just qualified and have only a student's knowledge of practical work. Should they not therefore be content with earning 20 per cent. more than the civilian medical man of mature years who is giving patients the benefit of his long experience? I am, Sir, yours faithfully,

Keswick, July 7th, 1918. W. D. ANDERSON.

EPIDEMIC ENCEPHALITIS.

To the Editor of THE LANCET.

SIR,—May I ask for space to refer to one or two points raised by Dr. Kinnier Wilson's paper on this subject in your issue of to-day?

1. The organism found by von Wiesner in the Viennese cases is, I am told by high bacteriological authority, indistinguishable from Rosenow's diplococcus, which has been, during the last two years, so generally found associated with poliomyelitis in New York, and of which, it is believed, the Flexner bodies represent one stage. The same organism has been identified recently in London.

2. Dr. Breinl concludes, on the basis of experimental results, that the Australian disease and acute poliomyelitis represent the same affection.

3. Wickman and others have recorded epidemics of poliomyelitis in winter and spring.

4. Leslie Carr has drawn special attention to stupor, and Koplik to ophthalmoplegia, in the New York epidemic of 1916.

5. In America in 1916 it was generally found that the changes in the cerebro-spinal fluid stood in relation with the "type" of case dealt with.

6. Of the cases that I personally have seen in London recently, quite a large proportion (perhaps 30 per cent.) were "meningitic" in type in a series of over 120 that included seven of the "ordinary" spinal kind.

7. Variations in type—clinical, epidemiological, and in respect of age-incidence—are the *rule* and not the exception if a series of outbreaks and epidemics of poliomyelitis are considered.—I am, Sir, yours faithfully,

Harley-street, W., July 6th, 1918. F. G. CROOKSHANK.

INSURED PATIENTS AND EXPENSIVE DRUGS.

To the Editor of THE LANCET.

SIR,—The case of Mr. F. C. Fisher reported in THE LANCET of June 29th shows that the Insurance Commissioners interpret an obligation undertaken by themselves in a different spirit from that in which they interpret an obligation undertaken by others. They profess that the benefits reaped by insured persons include the supply of appliances, but a practical experience of the Act shows that "appliances" does not mean "all appliances." Trusses, elastic stockings, and nasal irrigators have to be paid for by the patients who need them. Then why is a promise to supply "drugs" taken to include "all drugs"? The defence would no doubt be that the funds will not allow of the supply of trusses, &c., which is quite in accordance with the astonishing principle which runs through the Insurance Act, of not making sure that the cloth and the coat to be cut out of it correspond. Precisely the same argument, with immensely greater force, applies to the individual doctor and the drugs which he supplies. I am, Sir, yours faithfully,

East Grinstead, July 3rd, 1918. F. C. POYNDER.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue:—

Died.

Capt. R. N. Wallace, R.A.M.C., qualified at Edinburgh in 1907 and had held appointments at the Bradford Royal Infirmary, at the Manchester Children's Hospital, and at the Edinburgh Royal Infirmary. Prior to the war he held a commission in the R.A.M.C.(T.F.), being attached to the 6th Battalion, Royal Scots, and gave up an active practice at Edinburgh to devote himself to military duties in connexion with the war. He died at Colchester Military Hospital from acute pneumonia.

Lieut.-Col. W. McCall, D.S.O., R.A.M.C., was educated at Anderson College and at the University, Glasgow, and qualified in 1892. He was in practice in Birmingham, and prior to the war was attached to the R.A.M.C. (T.F.), being in command of the 1st South Midland Ambulance. The award of the D.S.O. was recorded in THE LANCET of Jan. 12th this year, p. 78.

Capt. P. J. Monaghan, South African M.C., qualified M.R.C.S.Eng. and L.R.C.P. Lond. in 1911, and later went to South Africa, from whence he came over with the South African Contingent in the early days of the war.

Capt. J. Anderson, R.A.M.C.

Lieut. L. F. Jamieson, R.A.M.C.

Wounded.

Capt. E. S. Cuthbert, R.A.M.C.

Major G. G. Timpson, R.A.M.C., attached R.F.A.

Previously reported Missing, now reported Not Missing.

Capt. J. P. McVey, R.A.M.C., attached Norfolk Regt.

Previously reported Missing, now reported Prisoners in German Hands.

Capt. G. L. Jones, R.A.M.C., attached Scottish Rifles.
Capt. R. M. Coalbank, R.A.M.C., attached Lancs Fusiliers.
Capt. C. W. Fowler, M.C., R.A.M.C., attached R. Berks Regt.
Capt. P. H. Green, R.A.M.C.
Capt. H. S. Moore, R.A.M.C., attached Lincs Regiment.
Capt. A. G. Clark, M.C., R.A.M.C., attached S. Lancs Regt.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Major C. F. Clarke, Indian Cavalry, died of illness contracted on active service, only child of the late Dr. J. F. Clarke, of Mitcham, Surrey.

Lieut. E. C. Rennie, R.G.A., attached R.A.F., died of wounds, son of Dr. G. E. Rennie, of Point Piper, Sydney, N.S.W.

Second Lieut. W. W. Pollard, R.A.F., died in hospital, only son of Dr. W. H. Pollard, of Birmingham.

THE HONOURS LIST.

The following are the statements of service for which the decorations recorded in THE LANCET of Feb. 9th, 1918, p. 234, were conferred. All are members of the R.A.M.C. except where otherwise stated:—

Bar to the Distinguished Service Order.

Maj. (temp. Lieut.-Col.) ARTHUR CARR OSBURN, D.S.O.—For conspicuous gallantry and devotion to duty. On seeing the enemy approaching close to his dressing station, he carried out the evacuation of the wounded under heavy shell and rifle fire in the coolest and most gallant manner. Having cleared away all cases by ambulance train and cars, he re-established his dressing station further in rear. As officer commanding bearer divisions he constantly inspected his line of bearer-posts and forward dressing stations under heavy fire. The successful evacuation of the wounded from the divisional front was due to his careful organisation and fearless supervision under the most trying conditions. His was an example of gallantry, courage, and resource worthy of the highest praise.

Distinguished Service Order.

Temp. Capt. FERGUSON FITTON CARR-HARRIS.—For conspicuous gallantry and devotion to duty. Hearing that ten men of another battalion were lying wounded in front of the position, he volunteered on completion of the relief to go to their rescue. He was out for eight hours of the night, found nine of the men alive, took two of them back to headquarters, and organised the rescue of the remainder. He showed great coolness and self-sacrifice.

Major (temp. Lieut.-Col.) CHARLES ALGERNON STIDSTON.—For conspicuous gallantry and devotion to duty when his dressing station was very heavily shelled throughout a whole day and received several direct hits. It was impossible to remove the wounded, and throughout the day he moved about continuously, arranging for their safety, with utter disregard of danger. It was owing to his fearless example and splendid organisation that all the wounded were finally removed without further casualties.

Bar to the Military Cross.

Capt. CUTHBERT DELAVAL SHAFTO AGASSIZ, M.C.—For conspicuous gallantry and devotion to duty when in charge of a bearer-post. He remained working throughout an intense bombardment, in which some of his bearers were killed and wounded while loading ambulance cars. He was compelled to remove to dug-outs, and there persisted in his work until shelled out. Though driven back three times by machine-gun fire and gas shell barrages, he succeeded in reaching the aid-posts with his bearers, and removed all the wounded.

Temp. Capt. ARTHUR JOSEPH BLAKE, M.C.—For conspicuous gallantry and devotion to duty. He did splendid work in collecting and evacuating the wounded, working throughout in the open regardless of the heavy hostile fire. Later he did excellent work tending the wounded of several units, going out after dusk to bring in wounded men from in front of our line. During the withdrawal he took out a party and carried back seven stretcher cases for a distance of three miles, thereby preventing these men from falling into enemy hands. He has at all times carried out his duties with fearlessness and courage.

Capt. ERIC ALFRED CHARLES FAZAN, M.C.—For conspicuous gallantry and devotion to duty. During very heavy fighting his aid-post twice passed into the hands of the enemy. Although all communication with him by day was cut off for two days, he remained with his wounded, 235 of whom passed through his hands. It was due to his determination that every wounded man and all the personnel of his aid-post were safely removed.

Temp. Capt. JAMES WALLACE MACFARLANE, M.C.—For conspicuous gallantry and devotion to duty. During a heavy bombardment of a battery position he assisted another officer and a sergeant in putting out the flames in a gun-pit which had caught fire. By his prompt assistance the gun was saved from serious damage and the ammunition from destruction.

Capt. SAMUEL McJAUSLAND, M.C.—For conspicuous gallantry and devotion to duty. He was in charge of bearers evacuating the wounded at a village under heavy shell and machine-gun fire. When almost the whole village was in the hands of the enemy he continued to supervise the collection of wounded, and it was mainly due to him and his bearers that they were all so speedily removed. In an attack he performed splendid work by clearing wounded of his brigade under most difficult conditions.

Capt. JOSEPH STEPHEN WALLACE, M.C.—For conspicuous gallantry and devotion to duty. Whilst in charge of an advanced dressing station and bearer squads he frequently visited the regimental aid-posts in the line and skilfully arranged his bearer squads to the best advantage. He also personally conducted ambulance cars to very advanced positions, thus being able to get a very large number of cases removed to safety in a short time. His coolness and courage during the whole period were a splendid example to his men.

The Military Cross.

Capt. ROBERT VACY CLIFFORD ASH.—For conspicuous gallantry and devotion to duty. When the enemy attacked and almost surrounded his dressing station he remained at his post under intense machine-gun and shell fire, attending to the wounded with complete disregard of danger. He got all the wounded safely away, and was instrumental in saving the transport and a large part of the personnel of the field ambulance. He then volunteered to return at once to the firing line, where he did excellent work in a most exposed position. He set a magnificent example of courage and devotion to duty.

Capt. ARTHUR JOSEPH BEVERIDGE, Spec. Res.—For conspicuous gallantry and devotion to duty. His dressing station was heavily shelled during an engagement, but owing to his determination, courage, and initiative a large number of wounded were attended to and evacuated from the danger zone.

Capt. JOHN HOLLIDAY BLACKBURN.—For conspicuous gallantry and devotion to duty. When 80 stretcher cases as well as a number of walking cases were handed over by another division, and owing to heavy shelling it was impossible to move them during the day, he took forward an ambulance as close up to the position as possible and organised the evacuation of the wounded. He showed splendid determination and resource.

Temp. Capt. JOSEPH VICTOR COPE.—For conspicuous gallantry and devotion to duty. He was in charge of stretcher-bearers in an exposed position, which was subjected to intense fire. Though he was suffering from gas he remained at his post for two days, setting such a magnificent example to his men that the evacuation of the wounded went on throughout the bombardment. By his courage and devotion to duty he saved many lives.

Temp. Capt. DAVID McMURRAY DICKSON.—For conspicuous gallantry and devotion to duty in tending the wounded under heavy shell and machine-gun fire. He was continuously out during the day searching the battlefield for wounded. He showed courage of a high order on this and many other occasions.

Capt. (temp. Major) JOHN DOUGLAS FIDDES.—For conspicuous gallantry and devotion to duty in continuing to dress the wounded under heavy shell fire at the advanced dressing station. Although the dressing station received a direct hit, he continued to work, and saved many lives by his courage and untiring energy.

Capt. JOHN HENRY PEARSON FRASER.—For conspicuous gallantry and devotion to duty in organising a new line of evacuation when the original line was blocked by the initial success of an enemy counter-attack. Many wounded had collected, but he got away over 100 stretcher cases, working unceasingly in the open for 36 hours.

Capt. PHILIP JACOB GAFFIKIN, Spec. Res.—For conspicuous gallantry and devotion to duty while in charge of stretcher-bearers during an engagement. He directed the removal of the wounded under heavy shell fire and showed great courage and resource.

Temp. Capt. HUGH BERNARD GERMAN.—For conspicuous gallantry and devotion to duty. When his dressing station was heavily shelled he organised the removal of 38 stretcher cases. He also rescued several wounded of another division under heavy shell fire. He established dressing stations without delay at various stages in an advance of four or five miles, and so enabled the wounded to be rapidly evacuated.

Temp. Capt. FRANK ARTHUR GRANGE.—For conspicuous gallantry and devotion to duty. He worked night and day without any rest attending to wounded from all units under continuous shell fire. He also went up to the front line under heavy fire to attend to a severely wounded man, and succeeded in getting him away.

Temp. Capt. EDWIN ALLAN THOMAS GREEN.—For conspicuous gallantry and devotion to duty. He worked with ceaseless energy, attending and evacuating the wounded. He moved his aid-post forward and worked under heavy shell fire till the enemy were within a few yards of his aid-post. He evacuated all the wounded save a few bad cases who could not be moved. His courage and presence of mind saved a large number of wounded from falling into enemy hands.

Temp. Lieut. ARTHUR COLLIS HALLOWES.—For conspicuous gallantry and devotion to duty when in charge of bearers. He succeeded in rapidly evacuating all the wounded under very difficult conditions. He attended to a severely wounded officer under machine-gun fire.

Temp. Capt. JAMES PHILLIPS JONES.—For conspicuous gallantry and devotion to duty. He worked in the line for a fortnight organising advanced dressing stations and bearer systems. During an enemy attack he was cut off from battalion headquarters, but established an aid-post and worked under heavy fire in the open for 36 hours attending to a large number of wounded. He showed the greatest courage and endurance throughout.

Temp. Capt. FREDERICK BENNETT JULIAN.—For conspicuous gallantry and devotion to duty. He remained at his post attending to the wounded during an engagement with great courage and determination though suffering severely from the effects of gas.

Temp. Capt. ARTHUR GRIFFITH MAITLAND-JONES.—For conspicuous gallantry and devotion to duty. During the operations he repeatedly reconnoitred the roads under heavy shell fire. By his example and leading he established communication with the most forward dressing stations, and succeeded in bringing up his ambulances and rapidly evacuating the wounded from very exposed positions.

Lieut. (temp. Capt.) WILLIAM WYLLIE MacNAUGHT.—For conspicuous gallantry and devotion to duty. He organised a bearer party during an action, and collected and cleared many wounded under heavy shell fire. His prompt and gallant action saved many lives.

Temp. Capt. JAMES MANUEL.—For conspicuous gallantry and devotion to duty. During an enemy attack he showed the greatest courage in attending to wounded men who were lying in shell holes exposed to enfilade machine-gun fire. With complete disregard of his own safety he went from one shell hole to another attending to the wounded, and continued at this work after he had been wounded himself.

Lieut. JOHN MARSHALL, Spec. Res.—For conspicuous gallantry and devotion to duty. When in charge of stretcher squads he succeeded in evacuating all the wounded during a critical period of a withdrawal from a village, frequently going forward beyond the firing line in order to accomplish his task.

Temp. Capt. DUNCAN JOHN McAFEE.—For conspicuous gallantry and devotion to duty. When two attempts to remove a wounded man from a regimental aid-post had failed owing to the stretcher-bearers being killed, he at once led forward a third party and succeeded in getting all the wounded back to a place of safety under very heavy shell fire. He showed splendid courage and self-sacrifice.

Temp. Capt. FREDERICK BUICK McCARTER.—For conspicuous gallantry and devotion to duty. When after an attack there were heavy casualties, he continued to attend the wounded in an open road enfiladed by machine-gun fire, and undoubtedly saved many lives.

Temp. Capt. JAMES ALLEN MONTGOMERY.—For conspicuous gallantry and devotion to duty. On his own initiative he organised a line of stretcher-bearers to search "No Man's Land." He personally took charge of the party and was often under fire and within a few feet of the enemy.

Capt. GEORGE MORRIS, Spec. Res.—For conspicuous gallantry and devotion to duty. He moved his aid-post forward and worked there ceaselessly day and night until the battalion was relieved. The aid-post three times sustained a direct hit from an enemy shell, but he immediately found another aid-post and continued to dress the wounded under continual shell fire.

Temp. Lieut. DAVID ASSUR HENRY MOSES.—For conspicuous gallantry and devotion to duty in working continuously at his aid-post during three days' operations under heavy shelling. Frequently shells dropped close by, killing and wounding several men, but he remained at work and showed the utmost indifference to danger.

Temp. Lieut. EVAN EDWARD OWENS.—For conspicuous gallantry and devotion to duty. He carried on his work in a crowded aid-post under continual shell fire with the greatest coolness and determination. Though blinded by gas, he continued for four hours to supervise the treatment of stretcher cases.

Capt. HAROLD DOBSON PICKLES.—For conspicuous gallantry and devotion to duty when in charge of bearers. When a number of wounded were lying in a cellar and the adjoining building, in which a number of "P" bombs and S.A.A. were stored, was set on fire he at once went to extinguish it and remove the ammunition. While doing so he, a N.C.O., and a man were wounded, but he got them both under cover. An hour later a second fire occurred, and he again went out to extinguish it. For three days he worked without rest superintending the evacuation of the wounded.

Capt. JOHN ALEXANDER PRIDHAM, Spec. Res.—For conspicuous gallantry and devotion to duty. He was in charge of an advanced dressing station where there were a large number of wounded when the enemy attacked. The task of removing the wounded was an extremely difficult one owing to the proximity of the enemy and heavy shell and machine-gun fire, but he carried it out successfully, remaining on the spot until all the wounded had been evacuated. By his courage and devotion to duty he was the means of saving many lives.

Capt. WILLIAM ROBERTSON.—For conspicuous gallantry and devotion to duty in attending to the wounded in the open during an attack when the battalion was held up by heavy machine-gun and rifle fire, and several casualties occurred. When two companies were cut off by heavy machine-gun fire and sustained casualties he volunteered to try and reach them. His conduct throughout was most courageous.

Temp. Capt. LIONEL MATTHEW ROWLETTE, D.S.O.—For conspicuous gallantry and devotion to duty. He worked untiringly attending to the wounded under very heavy fire throughout the whole day, and set a magnificent example of courage and coolness to all.

Temp. Capt. CEDRIC RUSSELL.—For conspicuous gallantry and devotion to duty. He worked in the open attending to the wounded during an engagement with complete disregard of danger under heavy fire.

Temp. Capt. ROBERT RUTHERFORD.—For conspicuous gallantry and devotion to duty. He worked continuously day and night at his aid-post under continual shell fire. When the aid-post had twice sustained direct hits and he himself was suffering from severe concussion, he established a new post and remained at work under heavy fire.

Temp. Capt. BRIAN HERBERT SWIFT.—For conspicuous gallantry and devotion to duty. When the front line was driven back close to the battery positions he moved about throughout the day from one battery to another, wherever his services were needed, with utter disregard of danger under heavy fire. He remained on the spot until the batteries had withdrawn, and was the last to leave the position. He set a splendid example of courage and determination.

Capt. ARTHUR PEREGRINE THOMSON.—For conspicuous gallantry and devotion to duty. He worked untiringly and with utter disregard of danger, attending to the wounded under heavy fire for several days during an engagement. It was entirely due to his efforts and example that a large number of wounded were safely evacuated.

Temp. Capt. GEORGE DIBBS KING WALDRON.—For conspicuous gallantry and devotion to duty when in charge of a party of bearers. Though several times blown over by bursting shells, he succeeded in evacuating all the wounded of the brigade. On one occasion he assisted to carry a stretcher case through a heavy barrage. He continued to work till utterly exhausted.

Capt. DOUGLAS LARMER WALL.—For conspicuous gallantry and devotion to duty. He attended the wounded under heavy shell fire in most exposed positions. He showed great courage and determination.

Capt. JAMES ANDERSON YOUNG.—For conspicuous gallantry and devotion to duty. When the building in which a number of wounded were lying was heavily shelled, with the assistance of another man he succeeded in carrying all the wounded into a cellar, though shells were continually bursting in the building. He showed the greatest courage and determination.

Capt. JAMES CARRUTHERS YOUNG, Spec. Res.—For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station. When the village was continuously shelled he personally superintended the removal of many of the wounded to a safer position. During the night he had them all evacuated and established a new dressing station.

Capt. EDGAR DOUGLAS, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He directed his relay of bearers under heavy shell fire, and, though wounded, remained at duty until he was relieved.

Capt. AUSTIN DWIGHT IRVINE, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. During four days in the front line he worked day and night attending to the wounded, often under heavy shelling. When casualties occurred during an enemy barrage, without hesitation he left battalion headquarters and went to the assistance of the wounded.

Capt. GORDON LEIGH JEPSON, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He established an aid-post during an attack under heavy shell fire, and for over ten hours attended to the wounded in the open under enemy shelling. When the enemy shelled his position with gas shells, and a number of stretcher cases were lying outside the aid-post, he went out at great personal risk and put box respirators on all the wounded, and by his prompt action saved many lives. He showed the greatest courage and self-sacrifice.

Capt. JAMES GRANT MACNEILL, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He worked unceasingly in the open attending to the wounded under heavy shell fire During a gas-shell bombardment he adjusted his own box respirator on a wounded sergeant and obtained others for a number of stretcher cases who were unable to help themselves. His coolness and courage were a splendid example to all and undoubtedly saved many lives.

Capt. WESLEY HERBERT SECORD, Canadian A.M.C.—For conspicuous gallantry and devotion to duty when in charge of the evacuation of the wounded from the forward area. During a heavy bombardment of gas and other shells he made a tour of all the bearer-posts to ensure that all anti-gas measures were being employed. He attended to wounded men in the open during the bombardment with complete disregard of danger. His coolness and courage were a splendid example to all.

Capt. WILLIAM EWING SINCLAIR, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. When in charge of bearers at the regimental aid-post he worked for three days and nights attending to the wounded under heavy fire and in the face of great difficulties. Though suffering severely from the effects of gas he remained at duty and set a magnificent example of courage and coolness to all.

Capt. REX CARRINGTON BREWSTER, New Zealand M.C.—For conspicuous gallantry and devotion to duty during an action. Throughout the day he was continually exposed to heavy shell fire while attending to the wounded, and set a splendid example to all ranks by his devotion to duty and contempt of danger.

Lieut. S. DUTT, I.M.S.—For conspicuous gallantry and devotion to duty. He worked indefatigably and attended a large number of wounded belonging to various units at the aid-post, which was under heavy shell, machine-gun, and rifle fire. His absolute coolness and steady devotion to duty were a splendid example to all.

The following medical officers have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war:—

Capt. (temp. Hon. Lt.-Col.) D. J. Armour, R.A.M.C.; Col. W. H. Horrocks, A.M.S.; Lt.-Col. F. S. Irvine, D.S.O., R.A.M.C.; Col. (temp. Maj.-Gen.) G. B. Stanistreet, C.M.G., A.M.S.; Temp. Col. A. S. Woodwark, A.M.S.; Col. G. E. Armstrong, Canadian A.M.C.; Hon. Lt.-Col. G. W. Badgerow, Canadian A.M.C.; Col. A. Primrose, Canadian A.M.C.; Lt.-Col. C. H. Tewsley, New Zealand M.C.; Maj. C. Macpherson, Newfoundland Contingent.

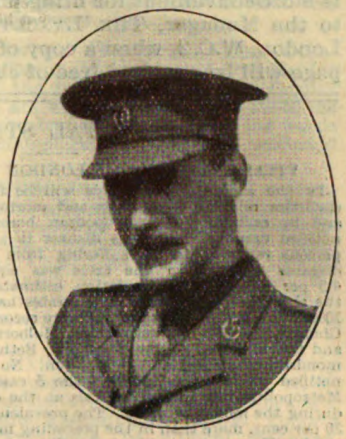
Captain Manley Angell James, M.C. (Gloucester Regiment), son of J. Angell James, L.R.C.P., M.R.C.S., of Nevil-road, Bristol, has been awarded the Victoria Cross.

OBITUARY OF THE WAR.

JAMES TENNANT WHITWORTH BOYD, M.D., C.M. ONTARIO,

CAPTAIN, CANADIAN ARMY MEDICAL CORPS.

Captain J. T. W. Boyd, who died at the Kitchener Military Hospital, Brighton, on June 16th, was 27 years of age, and son of the Rev. Andrew Boyd, of Port Arthur, Ontario. He obtained his medical qualification at Queen's University Medical School, Kingston, in 1914, and after spending a year at the Kingston General Hospital he enlisted in the C.A.M.C. and came overseas in February, 1916, when he was drafted to a Canadian General Hospital (Queen's University Unit) at Étaples. There he worked for a year in the laboratory until the results of a chronic scarlatinal nephritis necessitated his return to England, when he joined the staff of the Kitchener Hospital. In spite of the severe handicap of high blood pressure his work in the laboratory was consistently of the highest order, being characterised by a precise technique and an intellectual honesty which would have brought him to the fore had he lived. His death was due to uræmia. The photograph which we are able to give of Captain Boyd has been taken from a snapshot of a group.



PHILIP BEAUCHAMP SEWELL, M.D. MELB.,

CAPTAIN, AUSTRALIAN ARMY MEDICAL CORPS.

Captain P. B. Sewell, who was recently killed in action in France, was a student at Melbourne University (1911–16), obtaining his qualifying degree at a special War Final held in the latter part of 1916. He enlisted immediately, and for a short time was at a base hospital prior to embarkation. He was attached for a while as M.O. in a command depôt in England, and in August of last year went to France, where he was attached in succession to a field ambulance and an infantry battalion. During a counter attack on the night of April 24th–25th he was hit by a machine-gun bullet. His chief writes of Captain Sewell: "Throughout the winter he did most efficient work in watching over the good health of the battalion, and in all operations he proved himself a gallant, cheerful, and capable officer, and was a good comrade and well liked by both officers and men."

DEATHS OF WEST OF ENGLAND MEDICAL MEN.—Mr. Gillman Churton Pring Pauli, L.R.C.P. Edin., M.R.C.S., died at his residence, Redland, Bristol, on June 25th, in his seventy-ninth year. He was the son of the late Rev. C. H. Pauli, professor of ancient languages at Oxford University. Mr. Pauli was formerly in practice at Bedminster, Bristol, but recently had devoted himself solely to the duties of visiting surgeon to the Bristol City hospitals, with which he had been connected for 44 years. Mr. Pauli had a sound knowledge of infectious diseases. He was very popular and will be much missed in Bristol.—Mr. Vernon H. Starr, M.B., B.S. Lond., formerly house surgeon to the Royal Devon and Exeter Hospital, who was appointed in charge of the Peshawar Mission, N.W.F.P., India, in connexion with the Church Missionary Society, was murdered on March 17th. Dr. Starr was greatly respected in Exeter, and much sympathy is felt there for Mrs. Starr, who was with him at the time of the tragedy.—Surgeon Edwin John Gostwyck Sargent, L.M.S.S.A., R.N., died on June 25th at Bombay from the effects of sunstroke, in his twenty-sixth year. He was the son of Mr. W. G. Sargent, L.M.S.S.A., J.P., of Padstow, and grandson of the late Dr. H. E. Sargent, of Launceston. The deceased received his medical education at St. Bartholomew's Hospital, qualified L.M.S.S.A. in 1917, and entered the Royal Navy as a surgeon. He was highly esteemed at Padstow, and much sympathy is felt there for his relatives.

THE LANCET, VOL. I., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of June 29th is in preparation. Owing to the increasing shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a *post-card* (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

URBAN VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING JUNE, 1918.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 4·5 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 4·9, 3·9, and 4·1 per 1000. The lowest rates in June were recorded in Kensington, Fulham, Chelsea, the City of Westminster, Holborn, and the City of London; and the highest rates in Finsbury, Bethnal Green, Southwark, Bermondsey, Deptford, and Greenwich. No fresh case of small-pox was notified during the month; the 3 cases under treatment in the Metropolitan Asylums Hospitals at the end of May were discharged during the month of June. The prevalence of scarlet fever was about 20 per cent. more than in the preceding month; this disease was proportionally most prevalent in Finsbury, Southwark, Bermondsey, Wandsworth, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 846 scarlet fever patients at the end of the month, against 931, 898, and 786 at the end of the three preceding months; the weekly admissions averaged 127, against 132, 105, and 129 in the three preceding months. The prevalence of diphtheria was about equal to that in the preceding month; the greatest proportional prevalence of this disease was recorded in Stoke Newington, Bethnal Green, Stepney, Southwark, Bermondsey, and Lewisham. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1529, 1358, and 1232, numbered 1179 at the end of June; the weekly admissions averaged 165, against 182, 143, and 202 in the three preceding months. The prevalence of enteric fever was slightly more than in the preceding month; of the 41 cases notified in June, 9 belonged to Wandsworth, 5 to Hackney, 3 to the City of Westminster, 3 to Islington, and 3 to Battersea. There were 40 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 23, 23, and 32 at the end of the three preceding months; the weekly admissions averaged 6, against 3, 3, and 5 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, St. Pancras, Shoreditch, Bethnal Green, Deptford, and Greenwich. The 18 cases of puerperal fever included 2 each in Fulham, Southwark, Lambeth, Wandsworth, and Woolwich. Of the 13 cases of cerebro-spinal meningitis 3 belonged to Stepney and 3 to Lambeth; while of the 9 cases of poliomyelitis 3 belonged to Bermondsey and 2 to Woolwich.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended June 29th the deaths of 3655 London residents were registered, equal to an annual rate of 11·8 per 1000; in the three preceding months the rates had been 18·1, 17·1, and 13·7 per 1000. The death-rates ranged in June from 8·8 in Wandsworth, 9·1 in Woolwich, 9·3 in Lewisham, 9·5 in Paddington, 9·6 in Stoke Newington, and 9·6 in Battersea, to 13·4 in St. Pancras, 13·6 in Chelsea, 13·7 in Bethnal Green, 13·9 in Greenwich, 14·7 in St. Marylebone, 15·8 in Southwark, and 15·9 in Finsbury. The 3655 deaths from all causes included 336 which were referred to the principal infectious diseases; of these, 151 resulted from measles, 5 from scarlet fever, 45 from diphtheria, 98 from whooping-cough, 9 from enteric fever, and 28 from diarrhœa and enteritis among children under 2 years of age. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Paddington, the City of Westminster, Hampstead, Shoreditch, and Wandsworth; and the highest in Fulham, the City of London, Southwark, Bermondsey, Battersea, and Greenwich. The 151 deaths from measles were 30 above the average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Bethnal Green, Southwark, Bermondsey, Battersea, and Camberwell. The 5 fatal cases of scarlet fever were 9 below the average number. The 45 deaths from diphtheria exceeded the average number by 7, and included 5 in Stepney, 4 in Lambeth, 4 in Camberwell, 3 in St. Pancras, and 3 in Bermondsey. The mortality from whooping-cough was lower than in any of the preceding six months, the deaths numbering 98 against an average of 66; this disease was proportionally most fatal in Fulham, Islington, Finsbury, the City of London, Southwark, Deptford, and Lewisham. The 9 deaths from enteric fever agreed with the average; 2 belonged to Stepney. The 28 fatal cases of diarrhœa and enteritis among children under 2 years of age showed a decline of 40 from the average; 4 deaths belonged to Woolwich, 3 to Hammersmith, 3 to Greenwich, 2 to St. Marylebone, 2 to Islington, and 2 to Poplar. In conclusion, it may be stated that the aggregate mortality in London in June from these principal infectious diseases was 6 per cent. above the average.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE, 1918.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1917.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.									Deaths from all causes.	Death-rate per 1000 living.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Enteric fever.	Diarrhœa and enteritis (under 2 years).	Total. URBAN VITAL STATISTICS FOR WEEK ENDED JULY 6TH, 1918.

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 19·0 per 1000, which with one exception was the highest rate recorded in any week of the present year; in the three preceding weeks the rates were 11·4, 11·7, and 13·2 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 17·4, or 4·2 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 4·4 in Southend-on-Sea, 5·8 in Wimbledon, and 6·0 in Cambridge to 41·2 in Sunderland, 41·4 in Huddersfield, 44·6 in Middlesbrough, and 45·6 in Rochdale. The principal epidemic diseases caused 340 deaths, which corresponded to an annual rate of 1·1 per 1000, and included 142 from whooping-cough, 108 from measles, 42 from infantile diarrhœa, 33 from diphtheria, 10 from scarlet fever, and 5 from enteric fever. Measles caused a death-rate of 2·6 in Sunderland, 3·6 in Lincoln, and 7·6 in Barnsley; whooping-cough of 2·3 in Warrington, 2·8 in Merthyr Tydfil, 2·9 in Preston, and 3·0 in Walsall; and diphtheria of 2·3 in St. Helens. The 830 cases of scarlet fever and 1146 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 27 and 43 below the respective numbers remaining at the end of the previous week. The 1340 deaths from all causes in London included 218 from influenza, of which 110 were of persons aged 15 to 35 years. The causes of 77 deaths were uncertified, of which 23 were registered in Birmingham, 5 each in Liverpool and Sunderland, and 4 in South Shields.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 13·9, against 11·8 and 11·5 per 1000 in the two preceding weeks. The 273 deaths in Glasgow corresponded to an annual rate of 12·8 per 1000, and included 7 from whooping-cough, 3 each from measles, scarlet fever, and diphtheria, 2 from infantile diarrhœa, and 1 from enteric fever. The 82 deaths in Edinburgh were also equal to a rate of 12·8 per 1000, but no fatal case of the principal epidemic diseases was recorded during the week.

Irish Towns.—The 179 deaths in Dublin corresponded to an annual rate of 23·4, or 7·7 per 1000 above that recorded in the previous week, and included 4 from whooping-cough and a fatal case each of measles, diphtheria, and infantile diarrhœa. The 335 deaths in Belfast were equal to a rate of 44·4 per 1000, and included 6 from whooping-cough, 5 from infantile diarrhœa, 2 from measles, and 1 each from enteric fever and diphtheria.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology, held on June 27th and 28th and July 1st and 2nd, 81 candidates presented themselves, of whom 43 were approved and 38 were referred. The following are the names and medical schools of the successful candidates:—

A. H. Abdel-Messieh and M. V. Abraham, Manchester University; F. Blake, King's College; C. H. Bulcock, St. Bart.'s Hosp.; C. L. C. Burns, St Thomas's Hosp.; Marion Constance Vera Clarke, Royal Free Hosp; C. S. Cloake, London Hosp.; J. L. Cope, Cambridge University and St. Bart.'s Hosp.; P. G. Cumming, King's College; S. Douglas, Sydney University and University College; F. W. Crook, Guy's Hosp.; W. L. Dunlop, Liverpool University; F. T. Evans, St. Bart.'s Hosp.; H. Freeman, King's College; S. A. Gunter, St. Bart.'s Hosp.; R. Henein, Cairo and Manchester University; F. W. Herbert, Charing Cross Hosp.; H. D. Lawson, London Hosp.; K. W. Leon, St. Bart.'s Hosp.; W. B. A. Lewis, Cambridge University and St. Bart.'s Hosp.; G. M. Lewis, University College; Elizabeth Kathleen Mackay and A. Mikhail, King's College; L. S. Morgan, St. Bart.'s Hosp.; J. N. Morris, King's College; E. D. Nagel, St. Thomas's Hosp.; J. L. Nisbet, St. Bart.'s Hosp.; R. M. Patterson and W. Remington, Guy's Hosp.; Constance Elizabeth Ridout and Mary Jane Ripley, Royal Free Hosp.; L. C. Rogers, Middlesex Hosp.; Mary Frances Roope, King's College; I. Rosenberg, Guy's Hosp.; L. Smalley, St. Thomas's Hosp.; H. K. Snell, King's College; J. A. Stephens, Leeds University; E. R. Stearn, D. R. Thompson, and H. M. Toop, London Hosp.; A. R. Walker, Cambridge University and St. Thomas's Hosp.; J. G. Walker, King's College; and J. F. Weakley, University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: ELECTION OF MEMBERS OF COUNCIL.—A meeting of Fellows of the College was held at the College on July 4th, Sir George Makins, the President, being in the chair, for the purpose of electing four members of Council. The following was the result of the poll:—

	Votes.	Plumpers.
Sir John Bland-Sutton	410	37
W. G. Spencer	322	9
E. W. Hey Groves	307	25
J. Lynn Thomas	266	14
F. J. Steward	229	54
H. B. Grimsdale	185	28

The President declared that Sir John Bland-Sutton and Mr. Walter Spencer had been elected, and that Mr. Hey Groves and Mr. Lynn Thomas had been elected members of the Council. Five Fellows voted in person and 620 voted through the post. Mr. H. J. Price and Mr. Willmott Evans acted as scrutineers.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual general meeting will be held at the West London Hospital on Friday, July 19th, beginning at 5.30 P.M., when the report of the council will be read and officers elected for 1918–19.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, IRELAND.—The Reuben Harvey Memorial Prize has been awarded to William Robert Fearon, B.A., B.Sc., for an essay on "The Amylolytic Properties of Urine," and a second prize to Joseph Warwick Bigger, M.B., for one on "The Effect of Keeping on the Complementary Power of Guinea-pig Serum."

ROYAL MEDICAL BENEVOLENT FUND GUILD.—We may remind our readers of the garden party in aid of the Guild to be held in the Royal Botanic Gardens, Regent's Park, London, on Tuesday, July 16th, from 2.30–7 P.M. Lady Tweedy, chairman of the Guild, desires it to be known that inexpensive and useful gifts for the auction sales may be sent to her at 100, Harley-street, W. 1.

DEVON COUNTY MENTAL HOSPITAL.—The Committee of Visitors of the Devon County Asylum has decided to change the name of the institution to Devon County Mental Hospital. There are at present 1381 patients in the institution, and it has been arranged that some of the wards shall be fitted up to accommodate 200 sick and wounded soldiers.

PUBLIC HEALTH (TUBERCULOSIS) REGULATIONS, 1918.—In view of the recent alterations in the limits of age of men liable to military service, the Local Government Board have issued an Order requiring every medical officer of health to send to the Chief Commissioner of Medical Services particulars of every male person between the ages of 16 and 53 years notified as suffering from tuberculosis. The information, as heretofore, is to be regarded as confidential.

THE MCQUITTY EXHIBITION.—The McQuitty exhibition (founded as a memorial of the late Dr. W. B. McQuitty, physician to the Belfast Royal Victoria Hospital), awarded to senior students attending the Royal Victoria Hospital, Belfast, for excellence in clinical medicine, surgery, gynæcology, and ophthalmology (with pathology), has this year been gained by Mr. W. J. Lyttle.

BRISTOL ROYAL INFIRMARY.—The report for 1917 of the Bristol Royal Infirmary has just been issued. The medical statement shows that nearly 50,000 civilian patients and 4200 military cases were treated during the year. The adverse balance against the institution is now over £14,000. The committee make a strong appeal for increased financial support. What is more especially wanted is a regular income of £15,000 from annual subscriptions; at present this amounts to barely £10,000, but the Bristol residents have so generously supported their infirmary in the past that the required sum should be eventually raised.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The annual meeting of the association will be held on Tuesday and Wednesday, July 23rd and 24th, at Edinburgh. The presidential address will be delivered by Lieutenant-Colonel John Keay, R.A.M.C., at 2 P.M., on Tuesday, and papers will be read: Dr. W. Ford Robertson on "The Infective Factors in Some Types of Neurasthenia," and by Dr. Claud F. Fothergill on "The Prevention and Treatment of Neurasthenia and other Functional Nervous Breakdowns." On Wednesday, at 2.30 P.M., at the Edinburgh War Hospital, Bangour, Lieutenant-Colonel C. W. Cathcart and Major Rankine will give a demonstration on provisional artificial limbs, Sir Harold J. Stiles will show cases from the orthopædic department, Captain Edwin Bramwell cases illustrating functional neuroses, and Major D. G. Marshall and Dr. L. K. Davies will give a microscopical demonstration on malaria and dysentery.

WE are informed that a few cases of "influenza" can be received at the London Fever Hospital, Liverpool-road, London, N.

A SECOND edition of Sir Rickman Godlee's life of Lord Lister has just appeared (Macmillan and Co.), in which a few minor additions and corrections, chiefly of dates, have been made.

THE project of endowing a bed in the Royal City of Dublin Hospital in memory of the late Lieutenant-Colonel Henry Moore, R.A.M.C., has now assumed a definite form, and an influential committee has been elected for the purpose. Mr. G. Jameson Johnston, F.R.C.S.I., 13, Lower Fitzwilliam-street, Dublin, is the honorary treasurer.

UNDER the auspices of the London County Council a course of lectures on the Care of Mother and Child, with special reference to the work of midwives, is being given at the Birkbeck College, London, E.C., at 4 P.M. on July 15th and 22nd, by Dr. F. Truby King, C.M.G. The same course is also being given at the Morley College, Waterloo-road, London, S.E., at 4 P.M. on July 18th and 24th, by Dr. Truby King. The lectures will be illustrated by lantern slides and practical demonstrations.

Obituary.

SIR JAMES ACHESON MACCULLAGH, M.D. DUB., J.P.

WITH tragic suddenness the death of this well-known and much-esteemed member of the medical profession in Ireland occurred on the evening of Wednesday, July 3rd, in Roscommon. In his capacity as medical inspector of the Local Government Board for Ireland he had been engaged on the day of his death in his customary quarterly inspection of the Western District entrusted to his care. Half an hour before he died he had been seen walking through the streets of the town apparently in his usual health, which, however, had not been robust for some years. In the afternoon, while engaged in conversation he suddenly expired from valvular disease of the heart.

James Acheson MacCullagh was born in Dublin on Oct. 4th, 1854, and was the son of John MacCullagh, resident magistrate of Newry, co. Down, and of Wilhelmina, daughter of Acheson O'Brien, D.L., of Drumsilla, co. Leitrim. He was educated at Ennis College, co. Clare, and Trinity College, Dublin. He graduated in arts in 1875. In February, 1875, he joined the clinical class at the Meath Hospital and County Dublin Infirmary, and some two years later acted as clinical clerk to Dr. (now Sir) John Moore, physician to the hospital. In 1878 he graduated in medicine in the University of Dublin and in 1892 he proceeded to the degree of Doctor of Medicine, *stipendiis condonatis* in view of his attainments. Shortly after graduation Dr. MacCullagh became house surgeon to the Derry City and County Infirmary and the City of Londonderry Fever Hospital, having meanwhile taken the additional surgical qualification of the Royal Faculty of Physicians and Surgeons of Glasgow. He was also appointed a medical officer to one of the dispensary districts of Derry, and in that historic town he established his reputation as a painstaking and clever physician. Dr. MacCullagh became a member of the borough council, and in three successive years filled the office of Mayor of Derry; in 1896 he received the honour of knighthood.

Sir J. Acheson MacCullagh joined the medical staff of the Local Government Board for Ireland in June, 1898, and during the past 20 years the Western District has been the scene of his services. No part of Ireland makes greater demands on the energy and character of a medical inspector; it is subject to recurring outbreaks of typhus fever and enteric fever, though now happily to a much less extent than in past years. Working under such circumstances among a population of primitive ideas and habits, with sparse hospital facilities and undeveloped means of transit, and often cut off from ready communication with headquarters, a medical inspector needs to exhibit exceptional qualities of decision and resource. Sir Acheson MacCullagh in his long career was frequently called on to deal with epidemics of enteric and typhus fever under these conditions, and never failed to acquit himself with distinction. On one occasion in a remote island he had in face of a local panic to render personal assistance in removing typhus patients from their homes among the rocks and heather to the building which was fitted up as an emergency hospital. For his eminent services in this instance he was awarded the Order of St. John of Jerusalem. He could always be relied on to deal with a difficult situation with promptitude and sound judgment, and to his zeal and activity may be attributed the comparative immunity from serious outbreaks of fever which the isolated districts along the Atlantic seaboard have enjoyed in recent years. Although often called on to act with firmness, he succeeded in retaining the goodwill and support of the local authorities and officers with whom he was brought in contact. His long experience of typhus fever was constantly appealed to by medical officers in cases where diagnosis was obscure.

In an appreciative note to the writer of this memoir, touching the occasion and manner of Sir Acheson MacCullagh's death, his chief, Dr. E. Coey Bigger, Medical Commissioner of the Local Government Board for Ireland, writes under date July 6th:—

"I need hardly say that he was beloved by all who came in contact with him, not only in the department of the Local Government Board, but throughout his own district, where he was looked upon by the medical officers at large as a personal friend and a trusty adviser."

In 1880 he married Ida, a daughter of Mr. M. McClelland, J.P., of Glendarragh, Londonderry. J. W. M.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Maternity and Child Welfare Bill.

THE Maternity and Child Welfare Bill passed through Committee in the House of Commons on Tuesday, July 9th. The discussion turned largely on points connected with the machinery of local administration. A new clause in the names of Sir WATSON CHEYNE and Major ASTOR, proposing a transfer of the powers under the Bill to a Ministry of Public Health in the event of the latter being created, was ruled out of order.

HOUSE OF COMMONS.

WEDNESDAY, JULY 3RD.

Grading under the New Military Service Act.

Sir C. HENRY asked the Parliamentary Secretary to the Ministry of National Service whether he would state, of those medically examined who were within the new age-limit as provided by the Military Service Act, 1918, the percentage that had been passed into Grades 1 and 2.—Mr. BECK answered: The percentage of men placed by the medical boards in Grade 1 and Grade 2 is different in each year of age. A comprehensive percentage covering the whole of the new age-period would therefore tend to mislead those interested in the results of the medical examinations and yet would give information which might be of value to the enemy. In view of these circumstances it seems undesirable to publish the information asked for.

Commissions in the R.A.M.C.

Mr. PENNEFATHER asked the Under Secretary for War what qualifications were necessary to enable a man to be appointed a quartermaster and given a commission in the Royal Army Medical Corps; whether any Royal Army Medical Corps commissions had been given to schoolmasters, architects, and others as sanitary officers; and, if so, what were the qualifications necessary for the holding of such commissions.—Mr. MACPHERSON replied: Appointments of quartermasters in the R.A.M.C. are usually reserved for qualified warrant officers and non-commissioned officers and ex-warrant officers and non-commissioned officers of the R.A.M.C. In the early part of the war, owing to there being an insufficient number of R.A.M.C. candidates, a limited number of other persons were appointed. The officers of sanitary companies must be conversant with sanitary science but need not necessarily be medical men.

Appeal Tribunal on Officers' Disabilities.

Colonel ASHLEY asked the Parliamentary Secretary to the Ministry of Pensions whether he would give some information as to the composition of the appeal tribunal which dealt with the cases of officers who claimed that their disability was owing to, or was aggravated by, military service, but who had been unsuccessful in obtaining pensions; whether it included legal as well as medical members; when and where it sat; and whether he would state the steps necessary for an officer to take who desired to bring his case before such a tribunal.—Sir A. GRIFFITH-BOSCAWEN said in reply: The Appeals Board is constituted as follows: Chairman, Sir Ernest Pollock, K.C., M.P.; Sir Frederick Taylor, Bart., F.R.C.P., Sir Alfred Pearce Gould, F.R.C.S., and Captain Albert Smith, M.P. The Board meets at intervals as the cases to be dealt with require at Bridgewater House, St. James's. An officer whose appeal to the Ministry of Pensions has been considered and rejected may ask the Ministry for it to be referred to the Appeals Board. This is then arranged, and the officer informed of the date and place.

The Reported Deaths from Small-pox in Suffolk.

Mr. CHANCELLOR asked the President of the Local Government Board how many of the five small-pox deaths in the county of Suffolk reported in the quarterly return of the Registrar-General for the first three months of 1918 were civil, military, and naval respectively; and what was the vaccinal condition in each case.—Mr. HAYES FISHER replied: I am informed by the Registrar-General that the cases referred to were wrongly entered as small-pox. They should have been entered as whooping-cough.

Medical Treatment of School Children.

Mr. ROWNTREE asked the President of the Board of Education whether he could state the local authorities which were not providing medical treatment for school children.—Mr. HERBERT FISHER replied: The following is a list of the 39 local education authorities in England and Wales who, in 1917, did not submit schemes for sanction by the Board of Education under Section 12 (1) (b) of the Education Administrative Provisions Act, 1907, for medical treatment of school children: Isle of Ely, Kingston-on-Thames, Herefordshire, Morecambe, Hertfordshire, Middlesex, Mossley, Soke of Peterborough,

Ossett, Penzance, Staffordshire, Pontefract, Suffolk (East), Pudsey, Sussex (East), Royal Leamington Spa, Yorks (North Riding), Stalybridge, Carmarthenshire, Sutton Coldfield, Canterbury, Carmarthen, Dudley, Llanelly, Gateshead, Coseley, Great Yarmouth, Edmonton, Rotherham, Farnworth, Barnstaple, Felling, Berwick-on-Tweed, Ince-in-Makerfield, Congleton, Glossop, Oldbury, Hornsey, and Spenborough. In 1916 the number of such authorities was 43. It must not be assumed that all these authorities, while themselves incurring no expenditure, make no arrangements which secure, or aim at securing, the treatment of defects by private practitioners or voluntary organisations.

THURSDAY, JULY 4TH.

The Medical Service in France.

Sir WILLIAM COLLINS asked the Under Secretary for War whether, in view of the objections raised to recruiting medical men between 50 and 55 years of age and the allegations that medical men with the Army in France were insufficiently occupied, he had now further considered the desirability of making public the report of the committee which recently investigated the employment of medical men with the Army in France, and with what result.—Mr. MACPHERSON answered: There is no evidence that medical men in France are insufficiently occupied. It is not intended to publish the report of the committee.

Blackburn Medical Board.

Mr. SNOWDEN asked the Parliamentary Secretary to the Ministry of National Service whether he was now in a position to report the result of his inquiry into the methods of the Blackburn Medical Examining Board, who are passing totally unfit men into the Army.—Mr. BECK answered: Inquiries have been made into the methods of the Blackburn Medical Board, and no evidence can be found in support of the allegations made against it.

Medical Appeals in the Yorkshire Region.

Mr. JOWETT asked the Parliamentary Secretary to the Ministry of National Service how many appeals had been made on the ground of wrong grading as to medical fitness for military service at the West Riding of Yorkshire Appeal Court; and how many of such appeals had been granted.—Mr. BECK answered: The necessary information regarding the West Riding Appeal Tribunal is not available, but the following are the figures in respect of all appeal tribunals in the Yorkshire region during the period March 9th, 1918, to June 29th, 1918, inclusive: Number of applications made to an appeal tribunal in the Yorkshire region for re-examination by the medical assessors 1472, of which 252 cases have not yet been heard. Number of appeals allowed 283. It is not known in how many of these "appeals allowed" the medical assessors have altered the grading.

Extra Rations to Invalids.

Answering Sir FREDERICK HALL, Mr. PARKER (on behalf of the Ministry of Food) stated that food control committees were empowered to grant extra rations to invalids in the case of certain specified diseases only. Rheumatoid arthritis was not one of these. They were also empowered in any exceptional case of disease in which they were of opinion that a special allowance of meat or butter should be granted to forward the application to the Ministry of Food for the consideration of the medical adviser.

Supplies of Salvarsan Substitutes.

Mr. SNOWDEN asked the President of the Local Government Board what payments were made to the manufacturers of the salvarsan substitutes as supplied to local authorities, and from what funds were these payments made.—Mr. HAYES FISHER answered: The payments made by local authorities to manufacturers for supplies of salvarsan substitutes are at the minimum rates prescribed by the licences issued by the Board of Trade, and are at the same rate as those charged to Government departments for supplies of these preparations. The payments are made in the first instance from the funds of the local authorities, but 75 per cent. of their expenditure for this purpose is repaid by the Local Government Board.

MONDAY, JULY 8TH.

New Grading of the Older Men.

Answering Sir DONALD MACLEAN, Sir AUCKLAND GEDDES (Minister of National Service) said: Conferences have been held, with the President of the Local Government Board in the chair, between the Minister of National Service, chairmen of Tribunals, and other Members of Parliament, with the following result. It was agreed that the following classifications should be introduced for men of the new military age with regard to their fitness for military service. In future men of these ages passed by Medical Boards as fit for Grade I. will be classified as Grade I. (B i.). Similarly, men of these ages passed as fit for Grade II. will be classified Grade II. (B ii.), and those passed as fit for Grade III. will be classified as Grade III. (B iii.). These classifications will be distinctly marked on the grading cards. Instructions will be immediately issued by the Local Government Board to tribunals that in considering the relative military value of Grade I. (B i.) they must assume these men are "not fit to be trained for first line infantry," and that in considering the relative military value of men in the new classifications, Grade II. (B ii.) and Grade III. (B iii.), they must assume that they are of substantially less military value than men under the previous Military Service Acts who were placed in Grade II. or Grade III. respectively. Instructions will be given to each National Service representative that if and when requested by a tribunal he shall state whether a man placed in Grade III. has been found by the medical board to be fit only for sedentary work. Certain other points were discussed. The Minister of National Service informed the Conference that he had already issued instructions that no notice calling up a man of the new ages for service was to give shorter notice than 14 days, nor was it to be issued until ten days after the date upon which the man was due to report for medical examination. He further informed the Conference that he had instructed all Directors of National Service to see that the unauthorised use of books which recruits were asked to sign at medical boards, stating that they were satisfied with their examination, was to be discontinued, and that he had prohibited the adoption of any practice of this nature. It was agreed that greater publicity should be given to the opportunity of every man to apply for a second examination by a National Service Medical Board if he were dissatisfied with his first examination, and, further, that attention should be drawn by means of a printed intimation enclosed with the notice to report himself for medical examination of the limit of five days to the time within which he may apply to an Appeal Tribunal for permission to be examined by the Appeal Medical Assessors.

Mr. PRINGLE: Will an opportunity be given to the men who have come before tribunals to have their cases reopened in view of this decision?—Sir A. GEDDES: I do not think it would be quite easy to say that every case should be reopened, because many of the cases the tribunals might not wish to hear further. But I imagine that an application for a re-hearing will be considered.

Mr. ALBION RICHARDSON: Is it not the fact that a man is entitled as a matter of right to obtain a re-hearing of his case on the ground that a new and material fact has arisen since the case was last heard?—Sir A. GEDDES: He has a right to apply, but the tribunal may refuse the application.

Mr. FRANCE: Was the number of medical men on the board considered at the Conference and the length of time to be given to the medical examination?—Sir A. GEDDES: The number of doctors on the board was not discussed at the Conference. I think it was referred to once, but it was not discussed or made an important point.

Medical Grading.

Sir CHARLES HENRY asked the Parliamentary Secretary to the Ministry of National Service whether of those who were within the new age limit as provided by the Military Service Act, 1918, who were medically examined up to June 30th, the percentage passed into Grade I. and Grade II. was in excess of or below the percentage that he anticipated when the measure was passed; and, if so, to what extent in percentage.—Mr. BECK replied: Of the men medically examined up to June 29th who were above the former military age the percentage passed as Grade I. and Grade II. was about 12 per cent. less than anticipated. I must again point out that these percentages are based on a review at present necessarily incomplete and are liable to be misleading.

WEDNESDAY, JULY 10TH.

A Ministry of Health.

Answering Major ASTOR, Sir G. CAVE (Home Secretary) said: The proposal for a Ministry of Health Bill has been referred to the Committee of Home Affairs, and was considered by the Committee at its first meeting yesterday. After discussion it became clear that the proposal raised questions of some difficulty, and it was decided to adjourn the consideration of the Bill to a special meeting of the Committee to be held early next week. It is, I think, obvious that it would be impossible to pass such a Bill before the adjournment of the House in August next.

Major ASTOR: Will the Bill be introduced before the adjournment?—Sir G. CAVE: I cannot answer that until the Committee has decided.

At a later stage Major ASTOR proposed to ask leave to move the adjournment of the House in order to raise, as a matter of urgent public importance, the delay in introducing a Bill to set up a Ministry of Health.

The SPEAKER, however, in declining to allow the honourable and gallant gentleman to take this course, pointed out that a blocking motion was down on the order paper, and this, combined with the probability that there would be an opportunity of raising the matter within a reasonable time, shut out such a motion for the adjournment.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

R. B. Campbell to be temporary Fleet-Surgeon.

To be temporary Surgeons: D. J. Micah, J. V. Mainprize, D. S. Prentice.

To be temporary Dental Surgeons: T. P. H. Roberts, R. Page, J. C. Payne.

ROYAL ARMY MEDICAL CORPS.

Major A. L. B. Green, Hereford Regiment (T.F.), to be temp Major.

Temporary Captains relinquishing the acting rank of Major on re-posting: T. Martin, H. J. de Brent, A. S. K. Anderson, T. T. Higgins, F. C. Tibbs.

Temporary Captains to be acting Majors: J. F. R. Gairdner, J. McN. Murray, N. G. W. Davidson, H. Dudley, R. H. R. Whitaker, R. Hodson, J. G. Johnston, R. J. Vernon, S. J. L. Lindeman, A. M. Wood, R. R. Blair, W. B. G. Angus, H. C. Watson.

To be acting Majors while specially employed: Temp. Major M. Bridgman, Temp. Major C. M. Row, Temp. Capt. E. W. Willett.

To be Captains:—Captains from Special Reserve: R. A. Hepple, J. Y. Moore, A. L. Robertson, T. I. Dun, R. H. Leigh, H. G. Trayer, R. A. Austin, C. Popham, C. de W. Gibb, G. P. Kidd, S. D. Robertson, T. K. Boney, S. S. B. Harrison, H. D. Lane, F. C. Chandler, H. S. Milne, Q. V. B. Wallace, J. P. Quinn, J. B. Fotheringham; Temp. Capts. W. E. Adam, C. S. P. Hamilton, C. A. Bernard, R. E. Gibson, K. P. MacKenzie, E. G. Foley, S. Smith, J. H. Fletcher, J. H. Barry, G. D. R. Carr, D. H. Hadden, E. F. W. MacKenzie, C. Scales, A. Wilson, C. K. G. Dick, T. R. Snelling.

To be temporary Captains: Capt. S. S. Dunn (ret., Australian Army Medical Corps), attached R.A.M.C.; Temp. Lieut. A. J. Ferguson.

To be Lieutenants, and to be granted the temporary rank of Captain:—Captains from Special Reserve: F. J. Hallinan, J. H. Baird, W. D. Anderton, T. D. Inch, W. T. Hare, J. D. Proud, J. E. Rusby, J. H. C. Walker, M. B. King, W. Hunt, C. A. Slaughter, W. H. Ferguson, G. G. Drummond, F. G. L. Dawson, W. M. Cameron, A. Rodd, D. J. Batterham. Temporary Captains: T. J. L. Thompson, A. G. P. Hardwick, R. D. Davy, J. M. McKenzie, A. J. Hickey, W. J. Robertson, C. Russell, W. J. Knight, R. A. Mansell, W. L. Partridge, W. D. Newland, L. S. C. Roche, G. T. Baker, G. T. Garraway, G. E. Spicer. Captains from Territorial Force: S. Robertson, R. T. Jones.

Temporary Lieutenants to be temporary Captains: W. F. Erskine, O. May, G. A. Hoffmann, R. Alderson, W. P. Miles, J. Lambie, H. O'H. O'Neill, C. W. Preston-Hillary, H. G. F. Spurrell, S. E. Atkinson, J. Avery, H. V. Mitchell, W. B. Wilson, P. W. Hampton, R. Crawford, K. McK. Duncan, J. Ritchie, W. Anderson, W. Lilico, H. B. Wickham, J. Hunter, J. F. Bridge, J. Wylie, S. D. Craig, L. Hutchinson, E. S. Prior, E. O'D. Graham, R. Duncan, H. O. West, E. W. Witney, S. H. White, G. H. C. Lumsden, A. E. Knapp, Q. Madge, O. V. Payne, G. W. Curtis, W. A. Allison, E. Tate, J. D. Ferguson, A. J. May, A. B. Sykes, A. C. Renton, R. H. Thomson, F. G. Ralphs, W. H. F. Eales, J. A. Wood, T. Clarke, H. R. Wright, F. W. Pollard, V. G. Best, T. Gillespie, W. E. Waymark, J. Williamson, S. Wood, J. A. McSweeny, R. E. G. Gray, A. E. Leapingwell, H. T. P. Young, H. M. Roberts, J. F. Peart, J. Brown, W. B. Primrose, W. Weir, J. B. Aickin, J. A. Mearns, W. Mair, J. Steward, G. A. Pratt, A. H. B. Hartford, R. Peart, W. W. Cawlow, P. Talbot, J. C. Wootton, A. W. Ewing, W. Rotherham, A. Evans, A. C. Russell, J. Wilson, C. M. Ockwell, J. Dunbar, T. P. Robertson, L. Welply, F. H. Fuller, N. E. Sampey, J. J. F. Knight, C. B. Ticehurst, F. W. MacKichan, R. Brown, J. Scott, F. H. Dodd, J. H. Jones, D. P. Lindsay, L. H. Werden, N. Gray, J. S. Wilson, C. L. Driscoll, E. E. Paget-Tomlinson, G. C. Anderson, H. W. Horan, R. G. Smith, P. D. Hunter, B. J. Cusack, E. A. Sanders, J. R. Munro, R. J. W. McKane, J. Ferguson, D. D. Ritchie, R. J. Bentley, S. H. Sweet, H. Spurway, A. I. Shepherd-Walwyn, G. E. Thornton, W. S. Graham, J. K. Manson, J. Dalgleish, J. L. Meynell, E. M. Mall, S. W. White, J. K. Reid, W. Tregea, W. B. Clarke, S. N. Galbraith, E. MacM. Mahon, J. B. Cook, J. Grogono, E. W. Grogono, E. P. Harding, B. Kelly, C. A. B. Horsford, C. A. Lawrence, J. B. Banister, J. Ellenbogen, E. Morrison, P. J. Hay, J. A. W. Ponton, J. C. Ryan, B. Suggit, F. H. Diggle, A. M. Malcolmson, A. Tait, M. S. Wood, A. R. Taylor, G. H. Hackney, O. Smith, J. Cross, C. H. G. Lyall, E. Morgan, T. A. Davies, T. Kennedy, B. B. Phillips, C. B. Gerrard, C. B. M. Aldridge, R. N. Woodsend, J. McGibbon, R. T. A. Patchett, L. Wayne-Morgan, A. H. Gray, F. Crooks, H. Baird, V. J. Rigg, M. Aikman, P. L. Pollard, W. Cook, R. S. Strachan, D. O. Fairweather, T. Fraser, C. Brash, R. Taylor, J. D. Oliver, J. A. Powell, J. N. M. Sutherland, A. Matheson, F. L. Thomas, J. W. A. Wilson, D. L. G. Radford, F. A. Morrison, D. P. Smith, P. A. Hendley, S. W. Swindells, A. Westerman, G. Eager, E. G. D. Benson, G. Milne, C. M. Stevenson, U. Marks, T. B. Vaile, A. H. Duckett, J. J. Todd, D. W. Tacey, H. R. Cran, R. N. Dunlop, J. G. Woolham, N. H. M. Burke, J. D. Hartley, J. D. Jones, G. Denholm, A. F. Waterhouse, M. D. Mackenzie, L. D. Callander, J. Dawson, H. C. Taylor, J. B. H. Holroyd, H. E. Middlebrooke, W. H. Parkinson, H. Maffin, T. Brodie, G. L. Langley, F. de R. Martyn, W. B. Peacock, A. O. Bisson, J. F. Lindsay, F. McG. Loughnane, C. Gray, G. D. Dawson, H. A. Mason, J. Gilchrist, J. Orr, J. W. McDougall, G. Mowat, D. R. C. Shepherd, C. L. Stewart, E. C. Roberts, H. F. Marshall, H. R. L. Allott, F. F. C. Willington, R. C. Pitt, A. J. Adkins, W. H. Gibson, J. T. R. MacGill, D. Longwill, M. J. Macauley, F. H. Mosse, D. P. Macdonald, L. D. Wright, R. Fraser, E. J. Manning, C. J. Taylor, W. Duguid, St. G. M. L. Homan, C. W. C. Harvey, G. E. A. Mitchell, T. R. Couldrey, P. J. O'Brien, J. Fortune, I. B. Richardson, C. H. Gunson, W. B. A. Moore, S. G. Johnson, R. W. Dale, A. G. Bland, A. S. Findlay, J. A. Hagerty, H. P. Wright, F. D. Scott, W. H. Gowans, A. G. Stewart, J. W. Robertson, G. Garland, A. R. Jennings, H. Thorp.

A. E. J. Barcroft and T. Bell, late temporary Captains, are granted the honorary rank of Captain.

Temp. Hon. Lieut. D. A. Bartley to be temporary honorary Captain.

Officers relinquishing their commissions: Temp. Major W. Robinson (on ceasing to be employed at the Sutherland War Hospital); Temp. Capts. K. M. B. Simon, F. M. Harvey, W. W. D. Thomson, N. W. Jenkin, L. M. Davies, D. T. Evans; Temp. Lieuts. J. Rusk, N. Morris, P. J. D. O'Malley, W. R. Read, J. Good; Temp. Hon. Lieuts. C. S. Gilman, M. C. Pruitt.

Canadian Army Medical Corps.

Temp. Col. C. A. Hodgetts is seconded for duty with the Ministry of National Service.

Temp. Major J. G. W. Johnson to be acting Lieutenant-Colonel while specially employed.

Temporary Majors (acting Lieutenant-Colonels) to be temporary Lieutenant-Colonels: N. B. Gwyn, H. H. Moshier.

Temp. Lieut. R. Robillard to be temporary Captain.

F. D. Derrick to be temporary Lieutenant.

VOLUNTEER FORCE.

Medical Volunteer Corps.—City of Aberdeen: M.O. and Temp. Capt. W. S. Cheyne, from 1st Bn. City of Aberdeen Vol. Reg., to be temp. Capt. M.O. and Temp. Capt. J. O. Wilson, from 2/1st Bn. County of Aberdeen Vol. Regt., to be temp. Capt. M.O. and Temp. Lt. R. A. Slessor, from 1/1st Bn. County of Aberdeen Vol. Regt., to be temp. Lt. Anglesea: M.O. and Temp. Capt. G. L. Jones, from 1st Bn. Anglesea Vol. Reg., to be temp. Capt. Ayrshire: M.O. and Temp. Capt. W. McAlister, from 2/1st Bn. Ayrshire Vol. Regt., to be temp. Capt. M.O. and Temp. Lt. F. McKenna, from 1/1st Bn. Ayrshire Vol. Regt., to be temp. Lt. Banffshire: M.O. and Temp. Lt. G. C. Grant, from 1st Bn. Banffshire Vol. Regt., to be temp. Lt. Bedfordshire: M.O. and Temp. Capt. F. B. W. Phillips, from 1st Bn. Bedfordshire Vol. Regt., to be temp. Capt. M.O. and Temp. Lt. N. Edwards, from 2nd Bn., Bedfordshire Vol. Regt., to be temp. Lt. Berkshire: M.O. and Temp. Lt. J. T. R. Miller, from 1st Bn., Berkshire Vol. Regt., to be temp. Lt. Berwickshire: M.O. and Temp. Capt. J. MacWatt, from 1st Bn., Berwickshire Vol. Regt., to be temp. Capt. City of Bristol: M.O. and Temp. Capt. H. I. Owen, from 1st Bn., City of Bristol Vol. Regt., to be temp. Capt. M.O. and Temp. Capt. F. E. Peake, from 2nd Bn., City of Bristol Vol. Regt., to be temp. Capt. Buckinghamshire: M.O. and Temp. Lt. H. Barrett, from 1st Bn., Buckingham Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. J. D. J. Harris, from 2nd Bn., Buckinghamshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. H. T. Wickham, from 3rd Bn., Buckinghamshire Vol. Regt., to be temp. Lt. Cambridgeshire: M.O. and Temp. Lt. A. J. Laird, from 1st Bn., Cambridgeshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. F. Robinson, from 2nd Bn., Cambridgeshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. F. W. Mawby, from 3rd Bn., Cambridgeshire Vol. Regt., to be temp. Lt. Carmarthenshire: M.O. and Temp. Capt. E. Evans, from 1st Bn., Carmarthenshire Vol. Regt., to be temp. Capt. Carnarvonshire: M.O. and Temp. Lt. R. R. Jones, from 1st Bn., Carnarvonshire Vol. Regt., to be temp. Lieut. Cheshire; M.O. and Temp. Lt. L. C. A. Savatard, from 1st Bn., Cheshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. L. Pearson, from 2nd Bn., Cheshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. M. Young, from 3rd Bn., Cheshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. C. McA. Wilson, from 4th Bn., Cheshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. F. Cant, from 5th Bn., Cheshire Vol. Regt., to be temp Lt. M.O. and Temp. Lt. T. H. Smith, from 9th Bn., Cheshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. W. R. J. Garson, from 10th Bn., Cheshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. A. Banks, from 11th Bn., Cheshire Vol. Regt., to be temp. Lt. Clackmannanshire: M.O. and Temp. Capt. D. W. Currie, from 1st Bn., Clackmannanshire Vol. Regt., to be temp Capt. Cornwall: M.O. and Temp. Capt. A. J. Little, from 1st Bn., Cornwall Vol. Regt., to be temp. Capt. Cumberland: M.O. and Temp. Lt. J. R. S. Anderson, from Cumberland Motor Vol. Corps, to be temp. Lt. M.O. and Temp. Lt. F. H. Morison, from 1st Bn., Cumberland Vol. Regt., to be temp. Lt. Derbyshire: M.O. and Temp. Capt. G. S. Sims, from 1st Bn., Derbyshire Vol. Regt., to be temp. Capt. M.O. and Temp. Lt. W. E. Bond, from 2nd Bn., Derbyshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. W. R. Paton, from 3rd Bn., Derbyshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. A. Court, from 4th Bn., Derbyshire Vol. Regt. to be temp. Lt. M.O. and Temp. Lt. G. E. Sawdon, from 6th Bn., Derbyshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. S. J. Parkhill, from 7th Bn., Derbyshire Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. W. A. Walters, from 8th Bn., Derbyshire Vol. Regt., to be temp. Lt. Dorsetshire: M.O. and temp. Lt. G. G. Morrice, from 1st Bn., Dorsetshire Vol. Regt., to be temp. Lt. Dumbartonshire: M.O. and temp. Capt. J. R. F. Cullen, from 1st Bn., Dumbartonshire Vol. Regt., to be temp. Capt. City of Dundee: M.O. and temp. Capt. D. J. Forbes, from 1/1st Bn., City of Dundee Vol. Regt., to be temp. Capt. Durham: M.O. and temp. Lt. J. J. Weir, from 1st Bn. Durham Vol. Regt., to be temp. Lt. M.O. and temp. Capt. J. C. French, from 2nd Bn., Durham Vol. Regt., to be temp. Capt. M.O. and temp. Lt. S. G. Mostyn, from 4th Bn., Durham Vol. Regt., to be temp. Lt. M.O. and temp. Lt. N. Philipson, from 9th Bn., Durham Vol. Regt., to be temp. Lt. M.O. and temp. Lt. A. D. Kelly, from 12th Bn., Durham Vol. Regt., to be temp. Lt. City of Edinburgh: M.O. and temp. Lt. W. G. Aitchison-Robertson, from 1/1st Bn., City of Edinburgh Vol. Regt., to be temp. Lt. M.O and Temp. Capt. H. Hay, from 2/1st Bn. City of Edinburgh Vol. Regt., to be temp. Capt. Essex: M.O. and Temp. Lt. G. F. Wilson, from 1st Bn. Essex Vol. Regt., to be temp. Lt. M.O. and Temp. Capt. J. H. Salter, from 3/2nd Bn. Essex Vol. Regt., to be temp Capt. M.O. and Temp. Lt. F. Isdell, from 4th Bn. Essex Vol. Regt., to be temp. Lt. M.O. and Temp. Lt. G. F. Cooper, from 5th Bn. Essex Vol. Regt., to be temp. Lt. Fifeshire: M.O. and Temp. Capt. A. L. Curror, from 1st Bn. Fifeshire Vol. Regt., to be temp. Capt. County of London: M.O. and Temp. Lt. A. H. Gibbon, from County of London Vol. Eng., to be temp. Lt. West Riding: P. Bennett to be temp. Lt. Norfolk: R. Grant to be temp. Capt. Lancashire: Temp. Capt. G. Stowell to be temp. Major. Northumberland: M. Thompson to be temp. Lt. Kent: F. Holgate-Smith to be temp. Lt. Lincolnshire: H. S. McIntosh to be temp. Lt. Middlesex: Temp. Major P. G. Darvil-Smith, from Middlesex Motor Volunteer Corps, to be temp. Major. Suffolk: Lt.-Col. W. Keates (late the Suffolk Regt.) to be temp. Lieut.-Col; to be temp. Majors: Lieut. H. G. Wood-Hill (late R.A.M.C.), Lieut. H. E. Barnes (late R.A.M.C.), R. W. Mullock (late Surgeon-Captain, 3rd E.A., Howitzer Brigade), Capt. J. R. Dobbin (late R.A.M.C.), J. F. C. Hossack, A. M. N. Pringle, C. K. Moseley, D. A. Carruthers (late Captain, 1st Forfar R.G.A. (V.)); to be temp. Capts.: W. F. Fryer, H. P. Sleigh, D. N. Seth-Smith, G. H. Ransome, M. H. Mannigan (late Lt., 2nd V.B., Suffolk Regt.), G. I. T. Stewart, S. O. Eades, A. C. Young, G. R. Fox, F. C. Wetherell, E. A. C. Baylor (late Surg.-Lt. 1st V.B., "The Buffs," East Kent Regt.)

ROYAL AIR FORCE: *Medical Branch.*

The undermentioned are granted temporary commissions as Lieutenant-Colonels: Fleet-Surgs., R.N., R. H. Mornement, W. H. Pope, N. J. Roche, J. St. J. Murphy; Staff-Surg., R.N., H. Cooper. As Captain: A. E. Henton. As Lieut.: A. K. Soutar, F. H. Wallace.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

DALY, T. J., F.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Mullingar District of the county of Westmeath.

MACKENZIE, RACHEL E. W., M.B. Lond., Assistant Medical Officer of Health for the Borough of Woolwich.

ROBERTSON, D., Certifying Surgeon under the Factory and Workshop Acts for Aberdeen.

Vacancies.

For further information refer to the advertisement columns.

Alnwick Infirmary.—H.S. £150.
Birmingham, St. Chad's Hospital.—Res. M.O. £150.
Birmingham University.—Sen. Demonstrator of Anatomy. £250.
Bristol Education Committee.—Female Asst. School M.O. £350.
Bristol Royal Infirmary.—H.P. and H.S. £120.
Bristol University.—Demonstrator in Physiology.
Great Northern Central Hospital, London, N.—H.S. £100.
Hampstead General and North-West London Hospital.—Cas. O. £150.
Hospital for Consumption and Diseases of the Chest, Brompton.—Asst. Res. M.O. £100.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Asst. Phys.
Hospital for Sick Children, W.C.—H.S. £100.
Kensington Dispensary and Children's Hospital.—Res. M.O. £180.
Kensington and Fulham General Hospital, S.W.—Res. M.O. £250.
London County Mental Hospital, Coulsdon, Surrey.—L.T. Asst. M.O. 7 guineas a week.
Maidstone, West Kent General Hospital.—Sen. H.S. £250. Also Jun. H.S. £125.
Manchester County Asylum, Prestwich.—L.T. £7 7s. per week.
Manchester Education Committee.—Asst. School M.O. £350 to £500.
Ministry of Pensions, Allerton Tower Home of Recovery, Liverpool.—Res. M.O. £450.
Northamptonshire Sanatorium, Creaton.—Med. Supt. £300.
Portsmouth Royal Hospital.—H.S. £200.
Queen Mary's Hospital for the East End, Stratford.—H.S.
Royal Free Hospital, Gray's Inn-road, W.C.—Female Cas. H.S. (£100), and Gynæcological Registrar.
St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, E.C.—H.S. £250.
St. Mary's Hospital, Paddington.—Asst. Path. £100.
Sheffield Royal Hospital.—H.P. £140. Also Cas. O. £135.
Sheffield Royal Infirmary.—H.S. £120. Also H.P. £120.
Stockport Infirmary.—Jun. H.S. £200.
Stoke-on-Trent County Borough, Stanfield Sanatorium.—Asst. Tuberc. O. £360.
Walsall Education Committee.—L.T. Sch. Med. Insp. £400.
West London Hospital, Hammersmith-road, W.—H.S. £4 4s. weekly.
West Riding of Yorkshire, Maternity & Child Welfare.—Med. Prac. £400.
York City.—Temp. Tuberc. O. £500.
York County Hospital.—Female H.S. £200.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Aberdare, Glamorgan.

Births, Marriages, and Deaths

BIRTHS.

ALLNUTT.—On June 30th, at Hornchiffe-road, Blackpool, the wife of Captain E. Bruce Allnutt, M.C., R.A.M.C., of a son.

MEYER.—On July 2nd, the wife of Surgeon R. Meyer, D.O. Oxon., B.A., M.D., F.R.C.S.E., R.N., of a son.

RUXTON.—On July 1st, to Captain H. W. B. Ruxton, R.A.M.C., and Mrs. Ruxton (*née* M. H. Naylor, M.B., B.S. Lond.), of The Mall, Brentford, W.—a daughter.

MARRIAGES.

HARVEY—HENDERSON.—On July 5th, at the Friends' Meeting House, Golders Green, Surgeon W. F. Harvey, R.N., to Margaret Muir, elder daughter of John Henderson, of Coringham-road, London, N.W.

WARD—GOURLEY.—On July 3rd, at St. Mary Abbot's, Kensington, Temp. Surgeon George E. S. Ward, M.D., R.N., to Una, youngest daughter of the late Dr. Gourley, of West Hartlepool, and Mrs. Gourley, of Harrogate.

DEATHS.

COWAN.—On July 1st, at Tenby (suddenly), John James Cowan, M.B., C.M. Edin.

FOULERTON.—On June 29th, at Pembridge-villas, John Foulerton, M.D., F.R.C.P. & S. Edin., F.G.S., in his 90th year.

KEALY.—On July 6th, at Ashley House, Gosport, J. W. Gregory Kealy, M.R.C.S., L.R.C.P., aged 60.

SENIER.—On June 29th, at Galway, Alfred Senier, M.D., D.Sc., Ph.D., Professor of Chemistry and Lecturer in Medical Jurisprudence and Hygiene in University College, Galway.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.

Tuesday, July 16th.

GENERAL MEETING OF FELLOWS, at 5 P.M.
Ballot for Election of Candidates to the Fellowship. (Names already circulated.)

Wednesday, July 17th.

OCCASIONAL LECTURE by Colonel William Hunter, C.B., A.M.S., in the Robert Barnes Hall, at 5.30 P.M., on
"The Prevention and Arrest of Lice-borne Diseases (Typhus, Relapsing, and Trench Fevers) by New Methods of Disinfection. A summarized account of two and a half years' practical experiences in the Eastern War Areas." (Illustrated by lantern.)

MEETINGS OF SECTIONS.

EPIDEMIOLOGY.—This Section is specially invited to attend Colonel Hunter's Lecture.

Thursday, July 18th.

DERMATOLOGY (Hon. Secretaries—J. E. R. McDonagh, Henry MacCormac; Acting Hon. Secretary—S. E. Dore): at 5 P.M.
Cases will be shown at 4.30 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
Clinics each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.
(Details of Post-Graduate Course were given in issue of June 29th.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Out-patients each day at 2.30 P.M.

THE THROAT HOSPITAL, Golden-square, W.
MONDAY, July 15th.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

COLLEGE OF AMBULANCE, 3, Vere-street, Cavendish-square, W.
Course of Special Lectures and Demonstrations on Ambulance Work and First Aid (illustrated as far as may be possible and followed by a Discussion).
THURSDAY, July 18th.—4.30 P.M., Lecture X.:—Mr. G. F. Shee: The Work of the Royal National Life Boat Institution.

EDITORIAL NOTICES.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

Offices: 423, STRAND, LONDON, W.C. 2.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. G. R. Anderson, Southport; Australian Imperial Force, Lond., Surg.-Gen. of; Col. J. G. Adami, A.D.M.S.; Mr. W. D. Anderson, Keswick; Messrs. Adlard and Son and West Newman, Lond.

B.—Board of Agriculture and Fisheries, Lond.; Board of Trade, Coal Mines Dept., Lond.; Babies of the Empire, Lond., Sec. of; Capt. W. Langdon Brown, R.A.M.C.(T.); British Women's Hospital Nation's Fund for Nurses, Lond., Committee of; Mr. J. Bell, Lond.; Dr. C. A. Bucklin, Glasgow; Sir Thos. Barlow, Bt., K.C.V.O.; Dr. J. Brownlee, Lond.; Board of Trade, Asst. Sec. of, Lond.; British Museum (Natural History), Lond., Director of.

C.—Dr. F. G. Crookshank, Lond.; Dr. J. B. Christopherson, Khartoum; Children's Country Holidays Fund, Lond.; Dr. A. K. Chalmers, Glasgow; Mr. F. H. A. Clayton; Mr. J. H. Clements, Winkleigh; Mr. A. L. Cameron, New York; Major W. B. Cameron, M.R.C.; Mr. A. H. Cheatle, Lond.

D.—Dr. V. Dickinson, Lond.

E.—Eugenics Education Society, Lond.

F.—Mr. H. G. Fell, Lond.; Factories, Chief Inspector of, Lond.

G.—Pte. P. Gibson, R.A.M.C.(T.); Mr. F. Golla, Sunningdale.

H.—Major A. T. Henderson, C.A.M.C.; Dr. J. B. Hurry, Lond.; Prof. R. Howden, Newcastle-upon-Tyne.

I.—Ilford, Medical Officer of Health of.

J.—Capt. W. Jameson, R.A.M.C.

K.—Mr. W. Kean, Glasgow.

L.—London Hospital Medical College, Sec. of; London County Council, Chairman of; London and Counties Medical Protection Society, Sec. of; Local Government Board, Sec. of.

M.—Medico-Psychological Association of Great Britain and Ireland; Dr. N. Macleod, Shanghai; Mr. J. F. McMillan; Mr. J. Y. W. MacAlister, Lond.; Major W. E. McKechnie, I.M.S.

N.—Miss J. Neil-Kerrison, Smethwick; Norwich, Medical Officer of Health of; *National Food Journal*, Lond.

O.—Mr. J. Offord, Lond.

P.—Poole Rural District, Medical Officer of Health of; Dr. F. C. Poynder, East Grinstead; Mr. R. H. A. Plimmer, Lond.; Dr. F. Prosser, Rainford.

R.—Miss E. A. Rout, Lond.; Mr. R. T. Reynolds, Redruth; Royal Sanitary Institute, Lond.; Royal College of Surgeons in Ireland, Dublin, Registrar of; Dr. C. Rolleston, Stamford.

S.—Sir Edward Schäfer, Edinburgh; Dr. A. E. Stansfeld, Lond.

T.—Dr. J. Tatham, Oxted; Dr. C. J. Thomas, Lond.

U.—University of Durham College of Medicine, Newcastle-on-Tyne, Sec. of; Under-Secretary of State, Home Office.

W.—Capt. A. H. Watson, R.A.M.C.; West London Medico-Chirurgical Society; Major F. R. Walshe, R.A.M.C.

Notes, Short Comments, and Answers to Correspondents.

FOLK-MEDICINE IN THE ARAN ISLANDS.

IN her "Glimpses of My Life in Aran," Miss Hedderman, a district nurse, describes a number of survivals which in the past must have baffled medical men in many districts nearer the centres of civilisation than the remote and often inaccessible Aran Islands. Belief in the evil eye was once universal; it is still firmly rooted among the popular superstitions of the Western Irish.

"A child bitten by a dog was thought to have been 'looked upon,'" she writes, "by a person possessing this evil influence." A hydrophobia cure, once universal, had been resorted to and the child had been treated with a hair of the dog that bit it. The hair of the shaggy animal had been rubbed stiffly across the boy's mouth, causing intense torture to the bleeding patient. We are not told where the bite was, but we presume it was on the lips. The dog itself had had its hair dragged off and had then been drowned in the sea. It was three weeks before Miss Hedderman, a patient apostle of Listerism, could free the wound from the "hair-conveyed" poison by the use of warm boric lotion.

The "saliva cure" met Miss Hedderman at every turn in connexion with the evil eye. The person accused of casting a spell can also cure it by spitting. Sputum was doubtless once held to convey the soul or, like blood, to contain the soul and, on the homœopathic principle, the magician's soul can cure the evil wrought by the magician's eye. In cases of acute disease

"the first resort is the saliva cure, and should the person accused of casting the spell resent the insinuation and not be friendly disposed in that special direction, the patient's progress and relief from suffering are supposed to be hindered until he [the caster of the spell] enters the sick-room and saturates the bed-clothes with this filthy secretion."

A new-born child in Aran must be duly spat upon by the first person entering the lying-in chamber, and the compliment must be extended first to the mother, then to the medical man, nurse, or other attendant. The Aran islanders regard this spitting as a potent charm. In other parts of the world people spit on an object—a coin, for instance, in the case of a first sale in a new shop—"for luck." Readers of Dickens will remember that when Martin Chuzzlewit lay ill of a fever a local resident spat a kind of halo round the sick man's head. Dickens sees in this achievement only an instance of bravado and nastiness, and does not suggest the performance of some dimly remembered ritual similar to that described in Miss Hedderman's book.

Magic and witchcraft, like therapeutic virtue, are supposed to reside in certain persons or families. Thus the light-haired or red-haired woman is regarded as much of a witch, and this belief seems to point to a time when Ireland, inhabited by dark-haired people, was invaded by the Norse or the hated Saxon, or even by an older race.

Fairies, according to some folklorists, are the representatives in modern superstition of ancient races, often smaller in stature than those who have supplanted them. Fairies are mysterious, often malevolent, and given to kidnapping children, and this is the character often borne by an aboriginal race, driven into forests and swamps by newcomers and given to furtive reappearances and acts of treachery. The Aran islanders believe that fairies meet them in certain places, as for instance "on the rocks" of the lonely seashore, and that they there work spells on them, damaging to health.

A belief of the Aran Islands mothers is to the effect that sick children are changelings. Thus Miss Hedderman numbered among her charges a little golden-haired girl very ill of pneumonia. The mother, on being told that only the greatest care would keep the child alive, replied, sadly but emphatically: "She is gone; she has been taken by the fairies," who "have substituted 'that object,'" pointing to the poor little patient on the bed.

The Aran women, like all tribal women, are truer to the primitive type than the men, who travel and come under the influence of modern ideas.

RESUSCITATION FROM DROWNING.

IN THE LANCET of July 6th (p. 30), under this heading, we reported that Dr. F. J. Waldo, the City coroner, had called attention to the lack of proper provision in riparian districts for the resuscitation of people apparently drowned. Another aspect of the subject was dealt with at the College of Ambulance (3, Vere-street, London, W.), on July 4th, by Mr. William Henry, the founder and secretary of the Royal Life-Saving Society, who, on the occasion of the eighth of the series of lectures on First-aid, gave a demonstration of the methods of teaching the principles of saving life from drowning. Dr. T. N. Kelynack, who presided, said the objects of the Royal Life-Saving Society were to promote technical education in life-saving and the resuscitation of the apparently drowned, and to stimulate public opinion in favour of the general adoption of swimming and life-saving in schools and other establishments. Previous to the demonstration by a team of boys from Lady Owen's School, Islington, who illustrated the five methods of rescue, the three methods of release from the clutch of a drowning person, and the Schäfer method of resuscitation, Mr. Henry said that the society was started in London some 26 years ago and there were now branches in every capital in the British Empire, while in Australia and New Zealand it was subsidised by the Governments. In the London district last year the members of the society had saved the lives of over 200 people without the loss of a single rescuer. Swimming and life-saving were just as good exercises as cricket, and he hoped would some day be used instead of that sport in schools. It was not necessary for the rescuer to be a stronger person than the rescued nor an expert swimmer, and in the records of the Royal Humane Society for 100 years only two cases could be found of champion swimmers receiving awards for life-saving. The system was being taught at Harrow School, where the teaching was in charge of one of the senior boys. Sir James Cantlie, who moved a vote of thanks to the lecturer, directed attention to the importance of first-aid instruction, remarking that no first-aid was taught in hospitals to either nurses or doctors. While the Schäfer method of resuscitation might perhaps be the best for use in cases of drowning, it was impossible to use it in many accidents, on the operating-table, for instance, and other methods should not be forgotten.

[It may be mentioned that the Hunterian Lectures by Professor Arthur Keith (THE LANCET, 1909, i., 745, 825, 895) give, besides an historical summary of the Royal Humane Society, an account of the methods used since 1774 for the resuscitation of the apparently drowned.]

AN EXTEMPORISED CENTRIFUGE.

Major W. E. Home, R.A.M.C., sends us a note on an extemporised electric centrifuge devised by Private P. Gibson, R.A.M.C. (T.), first-class nursing orderly and laboratory attendant of H.M.A.T. *Essequibo*. The horizontal arm of a hand centrifuge with the buckets is taken and lashed to two of the arms of a ventilating fan hanging from the laboratory roof. When the fan is switched on the buckets fly out, the velocity reached being sufficient to throw down urinary sediments and even red blood cells. The device may be of use to others.

THE USE OF FRUIT-STONES FOR WAR PURPOSES.

A MEMORANDUM marked "Urgent" has been sent from the Local Government Board to town councils, urban and rural district councils, boards of guardians, and other Poor-law authorities, stating that *all fruit-stones*, including *date-stones*, and *hard nut-shells* are immediately required for an *urgent war purpose*. The National Salvage Council has been requested to arrange the collection of these materials, and they have already approached jam makers, hotel and restaurant proprietors, and secretaries of clubs, hospitals, and institutions. It is felt that Poor-law authorities and their staffs will gladly coöperate in this matter, and they are accordingly asked to ensure that the stones of all fruit consumed or made into jam in their institutions are collected and forwarded, carriage forward, O.H.M.S., to the Officer in Charge, Munitions Depôt, Southend Gas Works, Southend-on-Sea. Official labels will be issued shortly by the National Salvage Council, and stones should be carefully saved until these labels are received. In making jam all stones should be excluded. It is important that stones and nut-shells should be forwarded in a dry condition. Stones should be dried by being placed for a short time in the sun or in an oven. If possible stones should be packed in bags or sacks, fruit-stones being kept separate from nut-shells. Any inquiries should be addressed to the Director-General, National Salvage, Caxton House, Tothill-street, S.W.1.

Dr. J. C. Uhthoff has been promoted from honorary Serving Brother to a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England.

Dr. J. N. Langley, professor of physiology in the University of Cambridge, has been elected a foreign member of the Royal Academy "dei Lincei," Rome.

Professor Sir Edward Schafer wishes it to be known that he is adopting the name of Sharpey before the surname of Schafer.

AMONG the signers of the Declaration of Independence of the United States of America on July 4th, 1776, were the following physicians: Josiah Bartlett, New Hampshire, born in November, 1729; Lyman Hall, Georgia, born in 1731; Benjamin Rush, Pennsylvania, born Dec. 24th, 1745; George Taylor, Pennsylvania, born in 1716; Matthew Thornton, New Hampshire, born in 1714; and Oliver Wolcott, Connecticut, born Nov. 26th, 1726. They died at the ages of 66, 53, 68, 65, 89, and 72 respectively. There were six physicians, but 26 lawyers out of the 56 signatories.

Hunterian Lecture

ON THE

PATHOLOGICAL ASPECTS OF CERTAIN

WAR INJURIES OF THE EYE.

Delivered before the Royal College of Surgeons of England

BY W. T. LISTER, C.M.G., B.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,

TEMP. COLONEL, A.M.S.; CONSULTING OPHTHALMIC SURGEON, B.E.F.; OPHTHALMIC SURGEON, LONDON HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—While highly sensible of the honour of delivering one of the Hunterian lectures this year, I am conscious of the fragmentary nature of my communication. While in France it has been difficult to find out how far some of the observations are original or well known; indeed, if it had not been for the kindly encouragement of Sir John Bland-Sutton I should not have ventured to make this strain upon your patience. However, by means of photographs and ophthalmoscopic pictures I will show you some of the specimens obtained and lay certain views before you, in the hope that if anything important is therein contained the facts may be incorporated in some more complete work later on.

In this lecture I have selected various observations made on certain war injuries which appear of special interest from their novelty or comparative novelty, from the light they throw on other allied conditions, or from the contrast they draw between civil and military experience.

RUPTURES OF THE SCLEROTIC.

In civil life it is well known by far the greater number of ruptures take place either immediately above the cornea, or above and internal, and are situated about 3 mm. from the limbus.

In military practice, on the other hand, though similar injuries may be seen, yet other very different ruptures are met with. For example, the cornea may be burst forwards, or we find equatorial ruptures, or the whole eye may be split into numerous petals.

In endeavouring to find an explanation for the sites of ruptures, and the difference between those caused by the various forms of blows, one is faced by a complicated subject. Much has been written and many theories put forward to account for the site of civil ruptures, but even for these no one theory has received universal acceptation. No doubt the variations both in thickness and strength of the sclerotic, and in the amount of support the globe receives from surrounding structures, are important factors in determining the site of rupture. If, however, these were the *only* factors, one would expect that all ruptures would take place in one zone. As already noted, this is not the case, and, as we shall see, the site of rupture in the majority of cases, bears a special relation both to the site of impact and to the character of the blow. The following remarks I put forward tentatively till further experience is gained.

The first important point which stands out clearly is that unless the sclerotic is actually perforated by the missile itself, rupture does not start from the point of impact, but occurs at some considerable distance from it.

This is explained by the experiments of Rauber, who found when investigating the effects of blows on hollow spheres that the resistance of the envelope to pressure is one-third greater than its tensile strength (so that, for example, the eyeball would tend to burst at some distance from the point of impact sooner than give way at this point).

If we summarise our experience we find that the site at which ruptures take place is most commonly either in the equatorial zone about the line of impact, or opposite to the point of impact—i.e., at the point of contrecoup.

Also it would appear that these two sites of rupture are associated with two different kinds of blow.

I. The ruptures caused by slowly moving objects which strike the eyeball directly without penetrating globe or orbit, occur in the equator round the line of impact at a point where the globe is least supported.

This group will include the bulk of ruptures met with in civil life. They are caused by direct impact of comparatively slowly moving objects, such as stones, fists, boots, sticks, or cows' horns. The site of impact is at the anterior half of the eye, usually below or down and out, owing to the protection afforded to other parts of the eye by the brow and nose. The line of impact from a blow below the cornea will pass from below upwards and backwards; the least supported portion of the equator to that line of impact will be above the cornea—viz., the site at which civil ruptures usually occur.

II. In contrast to these we find that ruptures caused by rapidly moving missiles which pass through the orbit but do not strike the eye directly, occur at the side opposite to the point of impact—i.e., at the point of contrecoup. For example, missiles passing through the back of the orbit cause the cornea to be burst forwards, or if they have passed through the side of the orbit the rupture may be found near the equator on the opposite side.

I will now show some specimens illustrating these forms.

1. Rupture of cornea from passage of bullet at back of orbit.

2. Similar condition due to passage of bullet through both orbits. Both optic nerves were divided by missile; one at optic foramen, the other close to back of globe. In former globe was intact; in latter, though back of globe is intact the sclerotic around cornea is ruptured. Both eyes were proptosed, projecting right in front of lids; patient was complaining of such intense pain that, much against one's inclination, the two eyes were removed.

3. Large equatorial rupture on inner side of globe following passage of missile through outer side of orbit.

Causation of Different Forms of Rupture.

Our problem is to find out why the different forms of blows bring about the different forms of rupture.

When pressure is applied to the globe it would seem that there are two main methods by which rupture can be brought about.

(*a*) According to von Arlt's theory, indentation of the globe due to the impact of slowly moving missles, by lessening the diameter in the line of impact, must necessarily cause an increase in the diameter in the equator round this line. A sphere has the greatest cubic content for a given surface; any force, therefore, which distorts a hollow sphere containing a practically incompressible fluid, must bring about an increase of surface—that is to say, the envelope will be distended. The eyeball, being supported both at the place of impact and at the pole opposite to this, the distending force will be felt chiefly at the equator round the line of impact, and it is here, therefore, that distension will take place. And if the distension is sufficient to overcome the tensile cohesion of the sclerotic rupture will take place at some point on this equator where the globe is least supported.

This theory appears thus to account for the ruptures due to slowly moving bodies which strike the eye directly occurring at a site equatorial to the line of impact.

(*b*) When we come to ruptures caused by missiles passing rapidly through the orbit, quite a different set of conditions exists. The globe is not deformed by direct pressure, but is subjected to an indirect impact, or shock, due to the passage of the missile through the orbit. If the globe is not deformed the equatorial zone will not be over-stretched, and therefore von Arlt's theory will not afford an explanation.

I am greatly indebted to Professor Love, who has kindly considered the problem for me, and has suggested the following explanation.

The contents of the globe being fluid, sudden impact at one spot on the surface will cause a wave of pressure to radiate out through the vitreous from the point of impact; the more rapid the impact, the more forceful the wave of pressure; the slower the impact, the less forceful the pressure wave.

The wave of pressure will be felt most by the sclerotic exactly opposite to the point of impact, where the wave strikes at right angles to the surface, while at the sides, where the wave strikes obliquely, the pressure will be less felt. The wave of the sea which strikes the breakwater at right angles dashes much higher than the one which strikes it obliquely.

Again, where the incident wave strikes the sclerotic there will be a *wave of reflexion*, which will beat back against the incident wave. This wave of reflexion will only directly oppose the incident wave immediately opposite the place of impact; at other parts of the spherical surface the wave of reflexion will be directed more or less away from the incident wave.

Professor Love, when calculating the effects of air waves, found that where the wave of reflexion met the incident wave the pressure is enhanced, it may be as much as eightfold.

Though one cannot insist too closely on the similarity of the effects produced by air waves and those produced by waves in the semi-fluid vitreous, yet it would seem certain that a corresponding enhancement of pressure must take place in the eye at the point of meeting of the wave of reflexion and the incident wave.

It is common knowledge with what force the sea wave reflected from a breakwater meets the oncoming wave. So great is the pressure at this place that a mass of water is shot up into the air. In this instance the wave of reflexion beats back against the succeeding wave, but in the eye the wave of reflexion will beat back against the incident wave. In the open, the breakwater does not bear the brunt of this enhancement of pressure, but in a closed space, where no fluid can get away, this pressure must be borne by the walls.

Theoretically, the point of meeting of the incident and reflected waves will not lie exactly at the internal surface of the globe, but slightly nearer the centre of the eye. But this distance will be infinitesimal, and this enhanced pressure will be transmitted to, and borne by, the sclerotic immediately opposite the point of impact.

It would therefore appear that the stress on the sclerotic produced by the incident wave, plus the enhancement of pressure due to the meeting of the incident and reflected waves, will be far greater at the point of contrecoup than at any other part of the globe.

This view put forward by Professor Love seems to be highly satisfactory.

To recapitulate. The explanation for these different types of rupture would seem to be, that there are two forms of impact which have two different effects.

(1) The comparatively slowly moving blunt object striking the eye directly causes great deformation of the globe, but owing to the impact being slow there will be a weak pressure wave. This brings about ruptures in the globe round the line of impact.

(2) The rapidly moving missile passing by the side of the globe will cause little deformation, but the vibration set up by its passage through the orbit will cause a powerful pressure wave, which will bring about a contrecoup rupture.

III. We have, lastly, to consider the ruptures of the eye caused by a missile passing through the eye.

When the foreign body passes through the *back* of the eye the cornea is shot forwards and the contents ejected, which is comparable with the effect produced by firing a bullet through a canister full of water—both the lid and the water are shot upwards. Specimen 4 shows almost complete tearing away of the cornea due to a fragment passing through the posterior part of the globe and orbit.

When a sufficiently large fragment enters the eye in *front* there is an explosive effect, and the sclerotic is split into numerous petal-like lobes by radial ruptures extending backwards from the point of entrance.

The elasticity of the sclerotic will accommodate the entry of small particles without rupture. When, however, the fragment is of such a size and has such velocity that the united effect of the increase in volume caused by the entry of the body, together with the distending force of the pressure wave set up by its impact, is sufficient to overcome the elasticity of the supporting coat, widespread ruptures occur splitting the sclerotic into leaves. The point of entry determines the point of cleavage and the ruptures radiate backwards often close up to the optic nerve, so that when the sclerotic is removed it resembles the calyx of a flower. I can show you two specimens illustrating this form of rupture.

5. Where a small particle passed right through eye into orbit. The sclerotic is seen split into numerous leaves, the leaves radiating out from point of entrance.

6. Where two large splinters of wood were driven into the eye, splitting the sclerotic into two halves.

IV. In a separate group I would place certain other ruptures we have seen, which do not quite conform to the above-mentioned types.

7. A missile passing across lower margin of orbit caused an unexpected rupture. There was a vertical slit through centre of cornea, extending from limbus below to a point in sclerotic 6 mm. from limbus above.

It is difficult to explain this specimen satisfactorily. One would have expected on the above theory a superior rupture in the region of the equator. It is possible that the missile was not travelling fast and the eye was squeezed against the orbit above, and that the cornea was ruptured like the skin of a grape pressed between the finger and thumb in a line parallel to the line of impact.

8. A large mass struck the orbit up and in, fracturing frontal bone over frontal sinus. It caused a concentric rupture of sclerotic practically at equator, extending from immediately above cornea to a point in anterior inferior external quadrant. In this case the rupture runs parallel (i.e., meridional) to line of impact in equator round the line of impact, and conforms more with the civil type. One would have expected, however, that the cornea would have given way, being the least supported portion of this equator.

9. In another case a blow at lower margin of orbit caused T-shaped rupture—i.e., there was a concentric rupture 3 mm. from cornea above, from centre of which a radial split ran backwards almost to optic nerve.

Why the rupture in the equator to the line of impact runs sometimes parallel to this line, as in the tensile fractures of the skull, and sometimes at right angles to this line is probably due to the anatomical arrangement of the fibres of the sclerotic and to its varying thickness.

With the three variants—(1) thickness of sclerotic in different zones; (2) support of surrounding structures to different parts of globe; (3) site and nature of impact, above or below, outside or inside, direct or indirect, rapid or slow—one would expect considerable variety in the resulting ruptures. I do not suggest that the above theories completely explain all the ruptures that are met with. They appear to account for the main types, but we have come across several ruptures which certainly need further elucidation.

Comparison with Fractures of Skull.

It is interesting to compare ruptures of the sclerotic with fractures of the skull, though the dissimilarities of the two structures prevent the comparison being very close.

In both we have more or less spherical bodies with a semi-elastic envelope and practically incompressible semi-fluid contents. The skull has numerous bony buttresses and great variation in thickness of its walls, but no external support. The eye, on the other hand, has some, though less, variation in structure, but it is set in the conical bony-walled orbit, padded round with fat and muscles, which give it definite support for at least the posterior two-thirds of its surface.

In the skull we find three main types of fracture: (1) The "bending" fracture at the site of impact; (2) the "tensile" fracture occurring at a distance from the point struck, somewhere on the equator to the line of impact, the site being determined by the bony buttresses and the varying thickness of the skull at different spots; (3) the "explosive" fracture due to a large penetrating missile exerting a hydrodynamic force.

Explosive fractures of the skull and explosive ruptures of the sclerotic are directly comparable. Tensile fractures of the skull also correspond closely with those ruptures of the sclerotic due to the impact of slowly moving bodies which strike the eye directly. On the other hand, bending fractures of the skull cannot satisfactorily be compared with direct wounds of the sclerotic caused by the penetration of a missile, since there are no changes in the sclerotic to compare with the splintering of the skull at the part struck.

The point of special interest, however, in the comparison is the apparently rational revival of the old theory of fracture by contrecoup, a theory which has been described as "mechanically wrong, though still remaining popular."

Contrecoup ruptures certainly occur in the sclerotic, even if they rarely occur in the skull. As mentioned above, the theory put forward by Professor Love appears to explain satisfactorily their occurrence in the eye. It would be expected that neither the more resistant skull nor the more solid brain would transmit the wave of pressure so readily as the more elastic sclerotic and the nearly fluid vitreous. Thus it would be inferred that fracture of the skull through contrecoup by the mode described above would seldom take place. Nevertheless, pressure waves must necessarily be set up by severe blows on the head, and these, with the enhancement of pressure by the beating back of the wave of reflexion against the incident wave, will be at any rate partially responsible for the bruising of the brain and membranes at the pole opposite the point of impact.

CONCUSSION CHANGES.

The next subject I will take is certain of the less common concussion changes.

Rupture of anterior layers of cornea.—As a result of a severe blow on the eye one occasionally meets with cases of rupture of the anterior layers of the cornea which give rise

to straight or curved superficial striæ. If in cases of some standing microscopic section is made through such striæ, it is found that there is a rupture of Bowman's membrane and a variable number of the anterior layers of the substantia propria, and that the epithelium has grown into the gap in the same way as epithelium grows into an operation wound of the limbus or after tattooing of the cornea.

These striæ of the cornea, though often similar clinically, are different both in origin and in microscopic structure from the nearly straight, radiating, anterior striæ met with in soft ruptured eyes, which are due to *folding or crinkling* of Bowman's membrane. The latter radiate across the cornea from the line of rupture in the same way that the posterior striæ, due to folding of the posterior layers of the cornea (i.e., the ordinary striate keratitis), radiate from an operation wound when there has been much bruising of the corneal tissue or when cyclitis has supervened.

Specimens.—10. Drawing of a case of anterior striation of cornea (probably due to rupture of Bowman's membrane). 11. Rupture of Bowman's membrane, showing gap in this layer and anterior layers of substantia propria, into which epithelium was grown. 12. Ingrowing of epithelium into wound at limbus. 13. Tattooing. 14. Crinkling of Bowman's membrane following rupture of sclerotic.

Retroflexion of iris.—One specimen of retroflexion of the iris has been met with which is of interest, since the condition, though frequently described, is seldom verified anatomically.

15. The photograph shows the tucking back of iris between ciliary body and equator of lens. Such a condition would clearly give rise to the appearance clinically of "apparent iridectomy."

Rupture of ciliary body.—Mr. Treacher Collins has described the form of splitting of the ciliary body which separates the longitudinal and circular portions of the ciliary muscle. It is easy to see in the specimen (16) that such splitting carried a little further would allow the iris and the internal portion of the ciliary body to slip back, and thus be another condition which gives rise clinically to "apparent iridectomy."

Hyphæma.—This photograph (17) shows the condition of enormous distension of the A.C. with blood, the lens and iris being pushed backwards. There is marked blood-staining of the cornea.

Complete dislocation of lens into vitreous is seldom shown accurately in pathological specimens owing to the ready displacement of the lens in the nearly fluid vitreous when mounting the specimen, but in this case (18) the lens has been held in position by the surrounding blood clot.

Multiple intraocular hæmorrhages.—Hyphæma, vitreous hæmorrhage, inter-retinal and subretinal hæmorrhages are all shown, as well as hæmorrhage which has penetrated inside the lens capsule. It is easy to see what havoc to nutrition and sight would be caused by such a blow.

Concussion changes of retina and choroid.—(*a*) Commotio retinæ is frequently seen in military practice and does not differ from the civil type. Several cases have been seen where early pigmentation of the macula followed commotio, either as fine peppering or as somewhat diffuse greyish-brown spottings.

Lieutenant W. had an irregular central scotoma, which had the same pattern as the pigmented area of the retina. The scotoma disappeared in the course of about three weeks, but the pigmentation persisted (19).

The only point we have noticed but not seen described is that in the late stages of commotio retinæ, when the white haze has disappeared, for several disc diameters round the macula the retina had a peculiar striated appearance, evanescent in character—that is to say, the striæ changed their position with alteration in direction of illumination, like the rippled-sea-sand retina. This suggests that the retina is still somewhat swollen and wrinkled.

(Commotio retinæ may reasonably be compared with concussion of the brain, of which the retina is a specialised portion. The swelling is probably due to œdema, which can well be accounted for by the bruising from the pressure waves, and is similar to the imbibition of fluid by other colloidal matter.)

(*b*) The more grossly concussed fundus met with in military practice, when unobscured by vitreous hæmorrhage, affords one of the most dramatic ophthalmoscopic pictures.

In the early stages we see widespread, rich red clouds of hæmorrhage, interspersed with gleaming white patches (20).

The hæmorrhages in the retina are both subhyaloid and in the substance of the retina, and often there are, in addition, choroidal hæmorrhages forming a background.

The white spots, glistening in appearance soon after the injury, gradually fade, and in course of time their place is taken by plaques of fibrous scar tissue. It has not yet, so far as I know, been definitely ascertained what is the histological character of the white spots, and therefore what it is which gives rise to their glistening appearance. It would appear likely that they are patches of coagulation necrosis, brought about by the rupture of the retinal and choroidal vessels in the immediate neighbourhood, and thus cutting off the blood-supply and nutrition of certain areas of the retina. This view is supported by the few sections I have seen so far. The sections showed areas of necrosis, but it could be definitely stated if the necrotic areas corresponded with the white areas seen clinically.

The fibrous tissue plaques frequently have a festooned outline and they are sometimes reticulated—i.e., perforated, as it were, by round or oval holes (21).

The probable reason for this festooned edge is that the plaque has been larger at one time and roughly circular; it became attached at certain spots to the retina, where its structure was not completely disorganised, so that as contraction took place the outline became bayed between the fixed points.

It is more difficult to account for the holes which occur in the plaques; but, on the supposition that complete absorption takes place at a certain spot, retraction of the fibrous tissue round this spot will leave an oval or circular hole.

Choroidal ruptures.—As the blood becomes absorbed choroidal ruptures are frequently revealed. We find not only the usual crescentic type situated near to and concentric with a disc, but occasionally others are seen radial to the disc and usually more peripheral. In addition we frequently meet with more or less stellate ruptures, both adjacent to the part of the globe struck and also at the macula.

Combined with choroidal ruptures *areas of retinal and choroidal atrophy* occur, often so intermingled with the fibrous tissue plaques that it is difficult to be sure of the respective boundaries of the three conditions when viewed ophthalmoscopically—viz., choroidal ruptures, areas of atrophy, and newly laid down fibrous tissue.

Pigmentation is commonly seen after the first few weeks. It may be either in irregular coarse patches, fine peppering, or in bone-corpuscle deposits.

Sites at which Concussion Changes Occur.

Blows on the front of the eye give rise to changes as a rule only at the posterior pole, at or around the macula. While missiles passing through the side of the orbit may cause concussion changes at three different situations: (1) Adjacent to site of impact; (2) at macula; and (3) immediately opposite site of impact.

(1) The area which is always concussed is that adjacent to the site of impact. (This is strikingly in contrast to rupture of the sclerotic from a similar injury, which frequently takes place exactly opposite the place of impact, as already noted.) So constant is this that in certain cases of wound on one side of the head, with no apparent disturbance on the other side with the exception of some blurring of vision, the ophthalmoscope by revealing concussion changes in the eye of this side will enable us to state with certainty, not only that a foreign body has passed across the head and through the orbit on the opposite side to the wound of entrance, but also to define its course—a piece of information which may be of great value to the general surgeon.

(2) The concussion changes found at the macula from blows on the front of the eye are common, and would be anticipated as the result of bruising at the site of contre-coup, but macular changes due to blows on the side of the eye are difficult to account for and the subject needs elucidation. The greater vascularity and delicacy of structure in this region renders it in all probability more vulnerable. They are often in a group quite distinct from the disturbed area adjacent to the site of impact, and a band of normal retina may separate the two (22). Such cases have corresponding fields of vision, which show two defects (23), a central or paracentral scotoma and a peripheral defect, separated from one another by a band where vision is retained.

(Commotio retinæ may also occur in two distinct patches—one central, the other peripheral—as has been described by other observers.)

(3) In some cases of a lateral blow on the eye hæmorrhages were seen immediately opposite the site of impact, which

corresponds with the bruising of the brain at the pole opposite to the point struck, and also with the site of the contrecoup rupture of the sclerotic.

Effect of Concussion on Vision.

This is neither the place nor the opportunity to give detailed notes of cases in which the vision has been watched, but our experience may be summarised.

Concussion may produce a profound impairment of vision both in lowering the acuity and in contracting the field of vision. In the majority of instances great improvement takes place in the early weeks, and in the milder cases recovery is complete, both in field and acuity; but in the severe cases there is some permanent loss of field, and the acuity remains persistently lowered.

No doubt the early improvement is due to the clearing up of the commotio and the superficial hæmorrhage in the retina and also the vitreous hæmorrhages; but the parts of the fundus where large inter-retinal hæmorrhages or coagulation necrosis have occurred never recover, and there is a permanent defect in the field corresponding closely in shape with the disturbed area of the fundus.

It is important to remember that in severe cases of commotio, sight may be completely lost for a few days—a fact which may be of the greatest importance in deciding the fate of a wounded and concussed eye.

For example, I was called to see a man whose eye was penetrated by and contained a non-magnetic foreign body, complicated by a prolapse of iris which was of two days' standing. No P.L. The patient was ill from other wounds, and it was therefore important he should have as few anæsthetics as possible. Should the apparently useless eye be removed, or should an attempt be made to excise the prolapse and leave a fairly safe though blind eye, giving it a chance of quieting down, even though it contained a foreign body? As the eye was blind excision was decided on, but for some reason was postponed for 36 hours, by which time vision had returned so far that he could count fingers with this eye. An iridectomy was therefore done, and the eye quieted down with useful vision.

It is important to look carefully for *rupture of the retinal vessels*. These occasionally occur and their discovery will account for an otherwise inexplicable contraction of the field of vision. I will show you a drawing (24) and a field (25) of a very interesting case in which there were combined very marked concussion changes with rupture of the inferior temporal retinal artery.

Lieutenant K. C. had transverse wound of face; entrance at R. lower lid and exit through L. orbit. The L. eye was shattered and removed. The R. V. was reduced at first to the barest perception of light. Later, in about a week, it had improved to hand movements in lower part of field. Fundus showed huge clouds of hæmorrhage in retina interspersed with white spots in lower half; upper half unaffected. After two and a half years the fundus still shows extensive changes below, atrophic areas, fibrous tissue plaques extending up to macula, together with pigmentation. Also rupture of inferior temporal artery, which accounts for field being practically horizontally hemianopic. But the acuity has so much improved that he can read J.8 with the aid of a magnifying glass, and his handicap at golf is 10. He has travelled to Algiers by himself, and is still in the Army doing useful work.

Occasionally one comes across cases where the defect in the field is curiously sharply cut, with no corresponding definition in the limits of the fundus change.

For example (26), a case with a roughly quadrantic but sharply defined defect in the field was associated with a faint greyness over only a small part of the corresponding portion of retina, so that a shallow detachment was diagnosed. The affected area in the fundus showed no sharply defined border. After some weeks festooned fibrous tissue plaques with areas of atrophy and pigmentation made their appearance, showing that severe nutritional changes had taken place.

One interesting case (27) we were able to watch was that of a large, nearly circular, *choroidal hæmorrhage* at the macular region.

The ophthalmoscope revealed a central purplish-red area over which the retinal vessels ran, while in its centre was a deeper purple area, evidently the macula, which appeared as a purple morello-cherry spot (as opposed to the "cherry-red spot" seen in embolism of the central artery). In the course of a fortnight the purple area was changed to a glistening white patch of the "melting snow" variety, at the edge of which a choroidal rupture began to be revealed. Finally the white patch disappeared completely, disclosing a large crescentic choroidal rupture (28) passing just behind the macula, with no trace of fibrous tissue or indication of previous hæmorrhage.

In the early stages of this case there was a large circular central scotoma, but later, when the hæmorrhage had cleared, central vision returned, and though it could not be improved beyond 6/60, yet with a 2 mm. object on the perimeter no definite scotoma could be discovered even after careful search.

The hæmorrhage was undoubtedly choroidal and must have infiltrated the chorio-capillaris layer to give rise to the ophthalmoscopic appearance. How was it the central scotoma was not permanent? It can only be supposed that the retinal nutrition was sufficiently impaired over the hæmorrhagic area as to cause temporary abrogation of vision, but with the absorption of blood and improvement in the circulation central vision, though with poor acuity, was restored.

Comparing the concussion changes of the fundus met with in civil and military life we see a striking difference.

In *civil life*, where concussion is due to blows of direct violence on the anterior half of the eye from comparatively slowly moving blunt objects, detachment of the retina and holes at the macula are comparatively common, while severe concussion changes are rare.

In *military practice*, where the concussion is produced for the most part by rapidly moving missiles passing through the orbit, detachment of the retina and holes at the macula are infrequent, while severe concussion changes are nearly constantly present.

SUPPURATIVE CHANGES IN THE EYE.

As would be expected from the large number of penetrating wounds of the eye in warfare, suppuration is all too commonly met with. But panophthalmitis, whether exogenous or endogenous, following war wounds is usually not of an acutely infectious type. There is seldom much pain, and tenonitis, with consequent proptosis and chemosis, is seldom marked.

In the *endogenous* or *metastatic* forms we have been much struck by the difference in the clinical picture, according to whether the anterior or posterior vessels of the eye received the septic embolus.

In cases where the anterior half of the eye is first infected there is early exudate in the A.C. and anterior portion of the vitreous associated with marked discolouration of the iris. Thus in the specimen shown (29) there was to be seen clinically a plug of exudate in the pupil, and a peculiar white ring of exudate like a collar all round the angle of the A.C., together with a whitish-green discolouration of the iris.

While in cases of primary infection of the choroidal or retinal vessels the first sign is a general diffuse œdema of the bulbar conjunctiva, associated with loss of fundus reflex and dimness of vision; there is no discolouration of the iris, and no sign of exudation in the anterior part of the eye in the early stages. In the course of about 24 hours there is slight proptosis, and the loss of sight is practically complete.

In eviscerating the globe in one case the anterior portion of the vitreous was quite pellucid, and for a moment the diagnosis seemed to have been wrong; but on scraping out the retina and choroid purulent masses appeared, which indicated the posterior site of infection.

Exogenous panophthalmitis provides the bulk of our specimens and is due to penetrating injuries.

1. Sometimes the vitreous shows a nearly even infiltration and as it shrinks the position of its greatest adherence to surrounding structures is clearly defined—viz., the pars ciliaris and the optic disc (30). Fuchs has pointed out that purulent infiltration spreads out into the vitreous from these two situations. Some of the specimens show well the early involvement of the papilla, by, as it were, a fountain of pus pouring out into the vitreous from the disc (31). In others one sees the purulent thickening of the retina immediately around the disc to be quite separate from the infiltration in the pars ciliaris (32).

2. When the infective process is mild and the inflammatory changes approach the plastic type, the vitreous, which may have become one homogeneous purulent mass, gradually shrinks, and in consequence the retina becomes detached. One specimen (33) shows well the dragging forward of the retina from just behind the ora serrata which, on section of the eye, gives rise to a peculiar configuration to its outline.

In pathological departments this dragging forwards of the retina from the ora towards the back of the lens, as the result of plastic cyclitis, is well known, but clinically it is not universally recognised. Thus occasionally after a penetrating injury, when all seems to be going fairly well except for continued injection of the eye, one sees, a week or ten days after the injury, a white reflex behind one portion of the lens. It may wrongly be inferred that panophthalmitis has set in; the eye is removed, but on section and microscopic examination it is found that there is no panophthalmitis, but the retina has been drawn forwards at this spot, by the shrinking of plastic exudate, from the ora to the back of the lens.

3. The absence of continuity in certain specimens you have seen, between the exudate at the O.D. and that at the anterior part of the eye, shows that the infection must be carried to the O.D. and that the inflammation has not spread

simply by continuity. This must take place by the transference of organisms or toxins along the lymph channels in the vitreous; and Cloquet's canal, forming a direct means of communication, is probably the main channel.

Such cases come into line with those of optic neuritis without infiltration of the vitreous following severe infective ulceration of the cornea, which are met with fairly often in the laboratory but seldom guessed clinically.

We may suppose the toxic matter passes through the cornea into the aqueous, in the same way as atropine or cocaine is absorbed, and from here it can pass into the vitreous and along the flue-like Cloquet's canal and set up irritation at the disc, exactly as in Giffard's experiments, the vermilion granules, injected into the front of the eye, found their way on to the physiological cup.

The irritating substance, having once arrived at the disc, may set up optic neuritis, and it may also cause inflammatory exudate to be poured out either into the vitreous or into the inter-retinal space immediately round the disc (34).

Exudate into the vitreous may be suppurative, as we have seen, or it may be plastic, in which case it may be replaced by fibrous tissue, which on shrinking will cause folding or even detachment of the retina.

On the other hand, contraction of the exudation in the inter-retinal space may cause the peculiar rosette-like folding of the retina occasionally met with. (Specimen (35) of rosetting of the retina at the O.D. following membranous conjunctivitis, in which there was no obvious continuity between the inflammation in the cornea and that at the back of the eye, the vitreous being quite clear.)

Such inflammatory involvement of the optic nerve with consecutive atrophy may well explain the surprising loss of sight in certain cases following ulceration of the cornea, which is out of proportion to what one would expect from the corneal opacities.

CHANGES IN THE VITREOUS.

When examining the vitreous in eyes which have been penetrated by a foreign body one is struck by the extraordinary variety of the changes that are met with. In some the track of the foreign body is clearly defined, either by blood, by pus, or by a fibrous band, or, again, the whole vitreous, more or less hæmorrhagic and infiltrated, may be found shrunk up around the track, but remaining attached (or as it were "pegged out") to the retina at a point at which the foreign body struck.

The foreign body, by penetrating the vascular coats of the eye from without or striking the retina and choroid within, often causes a hæmorrhage to take place at one or both spots. Such a hæmorrhage may merely follow the track of the foreign body, but often it is much more widespread and occurs in fans which correspond with no known structure of, or lymph channels in, the vitreous, which fans may be seen with the ophthalmoscope. Just as a bullet when passing through a limb causes splits in the muscles and fasciæ radiating from its track, into which blood and infective material will find their way, so it would seem a foreign body passing through the jelly-like vitreous may split this body in various planes into which blood and, at a later date, infective material may also spread. This seems a rational explanation for the widespread fans and planes of hæmorrhage and fibrous tissue that are met with, which do not correspond with any known lymph passages in the vitreous.

The vitreous, as we have seen, becomes adherent to the retina at the point where a foreign body strikes; yet allowing for rebounding of a foreign body more than once or twice, or the possibility of more than one or two foreign bodies being present, we come across many specimens where the vitreous has been pegged out at too many spots to be accounted for by either of these causes. Hæmorrhages from the retina which burst through the hyaloid into the vitreous will doubtless be a cause of adhesion between the two structures. One of the specimens (36) shows a conical hæmorrhagic tip to a vitreous adhesion, which supports such a view. The hæmorrhage being only at the point of the adhesion, it is probable the blood came from the retina.

It would seem probable that when rifts of the vitreous caused by the penetration of a foreign body reach the retina, either blood may follow up along the rift or a new hæmorrhage may start from the retina, and thus also a connecting link is formed.

Shrinking of the vitreous and absorption of the various inflammatory elements may go on till all that is left of hæmorrhage and infiltration is a series of strands or fans of delicate fibrous tissue attached in front to the back of the lens, or ciliary body, and behind to the retina (37).

Occasionally these strands are exquisitely delicate, as in the specimen shown (38), merely branching threads with a variable amount of pigment deposited on or in them.

Where the fibrous bands are attached to the retina (39) they may by their shrinking exercise considerable traction, bringing about puckering or folding of the retina; or actual detachment may occur (40), provided sufficient exudation has not been poured out to bind together the retina, choroid, and sclerotic.

It is probable also that certain of the tears and holes which occur in the retina are due to the attachment and traction of vitreous bands.

In any case fibrous vitreous bands must be looked upon as a decided menace, and one must therefore avoid as far as possible any procedure in ophthalmic surgery which is liable to cause a vitreous hæmorrhage. Thus, in removing foreign bodies from the eye, this is one of the strongest arguments for drawing at any rate the smaller magnetic particles forwards into the A.C. and removing them through an incision in the avascular cornea rather than withdrawing them through a new incision made in the vascular sclera and choroid, which very probably will create a fresh vitreous hæmorrhage.

It is recognised, of course, that not every vitreous hæmorrhage gives rise to fibrous tissue, and one may digress for a moment to discuss this point.

Fibrous tissue may follow hæmorrhage both from penetrating and non-penetrating injuries. It appears to follow mild infections fairly regularly, but infection, in the ordinary acceptation of the term, is not necessary for its formation.

As Parsons has pointed out, the fixed cells of the vitreous will not by themselves produce fibrous tissue; fibroblasts from already formed connective tissue must be present, and they can pass in either from the retina or choroid after rupture in the internal limiting membrane of the retina or the hyaloid, or both, has been brought about. But it is, so far as I am aware, unexplained.

(1) Why in certain cases of recurring vitreous hæmorrhage in young people described by Eales, fibrous tissue fans develop, while in others even large hæmorrhages clear up, leaving no trace of fibrous tissue.

(2) Why a subhyaloid hæmorrhage at the macula, in the specimen shown (41), left a star-shaped plaque of fibrous tissue at this spot, which by its contraction caused crinkling of the hyaloid; while, as a rule, such subhyaloid hæmorrhages clear up completely.

(3) Why choroidal ruptures are not followed by deposit of fibrous tissues.

(4) Why in glaucoma, hæmorrhages from the disc sometimes are followed by fibrous tissue development so that the cup is filled in, and even a large nipple-like projection extends into the vitreous.

EFFECT PRODUCED ON RETINA AND CHOROID BY PENETRATING FOREIGN BODIES.

A small fragment, after entering an eye, may pass on into the orbit, or it may strike and rebound off the retina, coming to rest far from its original track. This rebounding of foreign bodies in the eye is quite comparable with the bouncing of missiles inside the skull, an astounding instance of which was kindly given me by Colonel Percy Sargent, where a small fragment, after entering the skull, actually bounced twice on the inner surface of the cranial cavity before it came to rest after a curiously complex course through the brain substance.

I can show you drawings of a case of which the only explanation I can offer is that a fragment rebounded twice on the retina.

42. Shows scar in sclerotic at its entrance on inner side of cornea.

43. The fundus shows two scars on retina, one on inner, the other on outer side of disc, bridged across by a fan of fibrous tissue which can be traced forwards towards wound of entrance. The small inset on right shows foreign body glistening like a jewel in the blood-stained vitreous, situated far forwards and on outer side.

44. X ray localises foreign body at a spot which corresponds with the ophthalmoscopic estimation; and shows no other F.B. in orbit.

45. Diagram of the supposed track—viz., that the foreign body entered the eye on the inner side in front, struck the retina on inner side of disc, bounced across to outer side, and was again reflected, but this time forwards.

46. The field of vision shows two scotomata situated in the horizontal meridian, corresponding with the two scars on the fundus.

When a foreign body strikes the retina it will certainly bruise and in most instances cut it.

I will show you microscopic sections of a case at Moorfields in which a foreign body bounced on the retina and later was removed by means of Haab's magnet. The spot where the foreign body struck the retina was indicated by attachment of the vitreous (47, 48). The sections through the spot show the retina to be divided, and the gap thus caused is occupied by a plug of newly formed fibrous tissue which is continuous with the shrunken and hæmorrhagic vitreous, in which fibrous tissue is beginning to replace the blood.

In some cases the retina may become folded and puckered at the site struck (49).

Correlation of Lesions with Defects in Field of Vision.

The delicate localised lesions of the retina are in reality wonderfully neat physiological experiments, for which in peace-time it would be difficult to obtain either the subjects or a licence.

Though Usher, Dean, and Parsons, among others, by dividing portions of the retina in animals, have been able to trace out the course of the degenerated fibres in the optic nerve, they were unable to correlate these lesions with the defects in the fields of vision of the dogs and rabbits they operated upon.

But in these war experiments on man we *can* correlate the visible lesions with defects in the field, though we are unable to complete the examination by tracing the course of the degenerated fibres.

Thus we find that lesions above or below the horizontal plane cause a defect in the field out of all proportion to the local disturbance—i.e., there is a "distribution defect," in addition to the local defect due to the lesion. This is due to the lesion having not only damaged the spot which is struck, but has involved nerve fibres which were passing on to a more peripheral portion of the retina.

The distribution defect is fan-shaped from the point corresponding with the lesion and extending towards the periphery. The nearer the lesion is to the disc the greater the blind sector and vice versa, which agrees with the accepted distribution of the nerve fibres in the retina.

When the lesion occurs in the horizontal plane there is no "distribution defect," but the loss of the field is limited to the area corresponding with the lesion, as would be expected, for the fibres supplying the retina in the horizontal line arch round from the disc to their destination, and therefore these lesions would only involve the nerve fibres at their termination.

As an example we may take the case already described when the foreign body bounded twice on the retina. The defect in the field was two scotomata corresponding with the two lesions of the retina with no distribution defect or peripheral loss.

These sector defects following bruising of the retina are strikingly similar to the sector defects in the field following solitary patches of choroiditis described and worked out with such care by Hepburn, but I venture to disagree with his explanation.

He suggests that the inflammation in the choroid has not only blocked the choroidal circulation at the site of the patch, but thereby has cut off the blood-supply of a corresponding peripheral sector of the choroid; and in consequence the retina degenerates, bringing about a similar sector defect in the field of vision.

Such a theory demands not only that the choroidal circulation is divided up into separate sectors corresponding with each vessel, but that the circulation is terminal—that is to say, no anastomosis exists between the various sectors—neither of which hypotheses is proved, nor is it, in my judgment, probable. It has long been recognised that the ciliary and choroidal circulations anastomose fully, and therefore blocking of one short ciliary artery is not likely to bring about an anæmic area. Also, if such a condition did occur the ophthalmoscope would surely reveal some difference in the appearances of the functioning and non-functioning choroid; and he admits there is none.

It would seem more probable that the sector defect in the field in these cases is due to an involvement of the nerve fibres by the inflammatory process as they pass over the patch of choroiditis, and therefore that the visual sector defect is one of nerve distribution, and not associated with any supposed distribution of the choroidal vessels.

Case of Complete "Ring Field."

The last case I wish to bring to your notice is one of great interest, for which I am much indebted to Captain W. Stirling, R.A.M.C. A minute particle perforated the cornea, iris, lens, and vitreous, and struck the optic disc, a "bull's-eye."

There is an adherent leucoma, a hole in the iris (50), an opaque track through the lens (51), from which there extends a delicate fibrous band in the vitreous to the mass of inflammatory tissue covering the disc and parts immediately around (52). X rays prove the presence of a foreign body on the disc. The rest of the fundus is normal.

The astounding fact is that this lesion has caused a nearly circular *ring field* (53); that is to say, there is a very large central defect, and considerable peripheral contraction, between which is a nearly circular band in which vision is retained.

If we are correct, as seems likely, in thinking that the nerve fibres in the outer third of the disc supply the macular area, and the most peripheral fibres on the disc supply the retina immediately around, while those in the centre are the long distance fibres which supply the periphery of the retina, then the fibres in the intermediate horseshoe zone on the disc must pass to that portion of the retina corresponding with this "ring field" (54). It would have been almost unbelievable that a complete ring field could have been left, yet it has to be accepted as fact, for the field has been taken most carefully on two separate occasions at an interval of several weeks, and the two fields are practically identical.

I will not weary you with any hypothesis of how this foreign body caused these bundles of fibres to suffer. For the moment the important fact is—*that a wound of the disc can lead to a (double) concentric defect in the field.*

Three important points are suggested by this case—namely:—

(1) That the nerve fibres which are in association with the various concentric zones of the retina, and which will be distributed to the corresponding zones in the appropriate superior and inferior calcarine areas of the occipital lobes, are arranged in definite zones in the optic nerve.

(2) A second interesting point is that this case throws light on those cases with concentric defects in the field which have been attributed to, but not definitely proved to be the result of, disease of the optic nerve, such as retro-bulbar neuritis (e.g., Hancock's case of ring scotoma following lightning stroke). This case, with the definite physical lesion of the nerve which can be demonstrated, substantiates the view that these other cases may also be due to a nerve lesion.

(3) But perhaps the most suggestive interest of the case is the possible light it throws on the etiology of diseases associated with concentric defects in the field, such as retinitis pigmentosa. Several have tried to explain the ring scotoma in this disease by the "water-shed" theory of the choroidal circulation, but this theory does not account for the variable position of the ring, nor the cases where from the beginning there is no ring scotoma, but either peripheral contraction or a gradually increasing central scotoma.

This case gives support to the suggestion which Hancock and I, and possibly others, have put forward, that retinitis pigmentosa may be primarily a degenerative disease of the nerve. On such a theory all the various defects in the field can be well accounted for. There are doubtless obvious difficulties which have to be explained, such as why the pigmentation of the retina should occur with this form of nerve atrophy and not in another. Nevertheless, I think this view is worthy of consideration, supported as it is by this very unusual case.

CONCLUSION.

Before closing my lecture I should like to express my cordial thanks to Miss Glazebrooke and Captain Hopwood, R.A.M.C., for the care they have taken over making lantern slides from my negatives; to the Committee of Medical Research for allowing Sergeant Maxwell to make the beautiful ophthalmoscopic drawings for me; and to Sergeant Maxwell himself for all the care and skill which he has displayed.

METROPOLITAN HOSPITAL SUNDAY FUND.—Up to the end of last week the total contributions received amounted to £64,000.

Major-General Charles Henry Burtchaell has been elected an honorary Fellow of the Royal College of Physicians of Ireland.

WAR DEAFNESS,

WITH SPECIAL REFERENCE TO THE VALUE OF VESTIBULAR TESTS.

BY P. McBRIDE, M.D. EDIN.,
CONSULTING SURGEON,
AND
A. LOGAN TURNER, M.D. EDIN.,
SURGEON,
TO THE EAR AND THROAT DEPARTMENT, ROYAL INFIRMARY, EDINBURGH.

HAVING had the opportunity of examining a large number of men whose hearing has suffered during the war, we venture to hope that a brief record of our experience may prove of interest.

Classification.

The cases we have observed naturally fall into four categories:—

1. Those who heard well previously and in whom deafness had resulted from injury of the internal ear alone.
2. Those who heard well previously, but in whom middle-ear suppuration as well as injury of the internal ear had supervened.
3. Those in whom there previously existed deafness, but in whom the tympanic membrane remained intact, the deafness having become aggravated.
4. Those who previously suffered from chronic middle-ear suppuration.

Classes 3 and 4 may be dismissed in a few words. It goes without saying that patients coming under these headings often become more deaf after exposure to concussion, and so in cases of middle-ear or nerve deafness an increase of this symptom was often observed. In the course of our work we have seen very many soldiers with middle-ear suppuration, and it has occurred to us that the advantage of enlisting men who suffer from this condition is open to question. It is perfectly true that many of them hear sufficiently well to make useful soldiers, but it is also true that the existence of a condition which may at any moment give rise to serious symptoms makes it possible for them, if they so desire, to spend much of their time in hospital. If, for instance, a patient with chronic suppuration complains of headache, giddiness, and nausea even the expert will often find it difficult to distinguish between real illness and malingering. Moreover, it is impossible for a soldier on active service to have his ears properly attended to unless very special and expensive provision is made for this class of case.

Classes 1 and 2, in which, so far as could be ascertained, the hearing was previously perfect, afforded data of great interest. In the former the deafness was due solely to lesion of the labyrinth, while in the latter, although nerve deafness existed, there was also a second factor in the presence of chronic middle-ear suppuration, due to the fact that the explosion which had injured the cochlea had at the same time ruptured the membrana tympani. We have been much struck by the number of cases in which, where this occurred, the patients gave histories of having been buried by a shell explosion. Presumably under such circumstances there is greater probability of septic material getting into the middle ear. In some of these there were not only suppuration but granulations and even polypi as well.

Tests Employed: Vestibular Reactions.

In examining cases of primary concussion deafness, with or without suppuration, we adopted the various tests now in use.

Thus, bone conduction for a tuning-fork of medium pitch was noted, the hearing power for low and high tones was tested with tuning-forks, the Galton whistle, and frequently with the monochord as well. Vestibular tests, too, were employed in all the cases. In testing the hearing for the voice the opposite ear was excluded by employing Barany's noise apparatus. It is now recognised that if a normal ear be syringed with cold water a nystagmus results, the quick movement of which is away from the ear operated upon and which is most easily observed by making the patient look in this direction. This usually comes on after the water has been running into the ear for from 40–50 seconds, but too much importance cannot be attached to this time, as individuals react differently. Again, if a normal person be placed upon a revolving chair and rotated ten times in 10 seconds a nystagmus, the quick movement of which is opposite to the direction of rotation, will result and last from 20–40 seconds.

Now it has been suggested that if there is deafness following concussion, and if the vestibular tests give a normal result, we are therefore entitled not only to arrive at a favourable prognosis, but even to assume that the deafness is of purely functional origin. This proposition is very unlikely to appeal to anyone who has had opportunities of studying ear disease and utilised such opportunities intelligently. To such an one the evidence of his own pre-war experience will supply ample refutation. Space does not permit us in this communication to enlarge upon the many reasons that make the hypothesis untenable, but we hope to adduce proof that these vestibular tests—interesting and important as they no doubt are—must be considered of subsidiary value either in estimating prognosis or detecting malingering in cases of concussion deafness. We have thought it well to bring the matter forward as shortly as is compatible with clearness in a journal accessible to the medical profession as a whole rather than in one devoted to otolaryngology, because we believe that very grave injustice might be done if the dictum were accepted that given a man deaf from explosion, if he reacts to the vestibular tests in what his examiner considers a normal manner he is therefore either a malingerer or the victim of hysteria.

Group A.

Let us in the first place give brief records of five cases in which suspicion of either hysteria or malingering might be justified.

1. Blown up; unconscious; temporarily totally blind and deaf. When examined heard loud voice in each ear at 1 foot; deafness of the nerve type; cold water induced nystagmus in 60 seconds on the right side and in 40 seconds on the left, while rotation produced after nystagmus lasting 25 seconds both from right to left and from left to right.

The suggestion of possible hysteria is furnished in this case by the history of blindness and total deafness immediately following the injury.

2. Shell fell in trench; was uninjured, but quite deaf for two or three days, and also lost his voice. The latter returned and hearing is slowly improving. Was giddy after the explosion. When examined could hear a shout near the right ear and a very loud voice near the left; deafness of nerve type. Cold water produced reaction in 20 seconds from the right and 30 seconds from the left ear.

The loss of voice is in this case suggestive of hysteria.

3. Exposed to shell explosion; since has suffered from total deafness and loss of speech; general symptoms of shell shock. Both ears completely deaf to voice, tuning-fork by air or bone conduction, and Galton's whistle. Rotation from right to left had to be stopped at eight revolutions owing to hysterical manifestations, but only very slight nystagmus resulted. From left to right ten revolutions were tolerated and the after-nystagmus lasted only 12 seconds.

There was certainly hysteria in this case, as evidenced by the aphonia.

4. Knocked over once and buried twice during an advance. Deafness was complete at first, but now varies a little. Had shell shock, but now recovered. When examined heard only a shout near either ear, but he seemed to hear better when discussing his ailments. Bone conduction lost; Galton's whistle not heard; rotation right to left produced nystagmus lasting 35 seconds and from left to right 75 seconds.

Hearing better in conversation suggested possible malingering.

5. Buried by shell explosion and since then left ear has been deaf. Discharge said to come from right ear, but hearing on that side fair. Pain said to occur in right ear when discharge stops. Right tympanic membrane normal, but some impetigo of meatus. With the right ear hears a low voice at 15 inches, but with the left only a shout near is heard. Tuning-fork tests unsatisfactory as regards both ears and result in some obvious misstatements. Galton's whistle not heard by left ear. Rotation from right to left caused nystagmus lasting 10 seconds and from left to right 17 seconds.

A consideration of these cases, which, owing to collateral circumstances, might furnish just suspicion of the presence of a functional or malingering element, does not in any way justify the assumption that a normal vestibular reaction confirms this diagnosis. While Cases 1, 2, and 4 showed good and, in the last, even excessive reaction, it was found to be defective in 3 and 5. Again, in 4, although the hearing power of each ear was equally involved, one vestibule was much more sensitive than the other. It is worthy of note that in 5 both reactions were below normal, but that obtained from the deaf ear was the more pronounced.

Group B.

In the following cases there was diminished vestibular reaction.

1. Blown up by shell; total deafness in both ears. Cold irrigation caused no reaction after 140 seconds on the right, while nystagmus followed in 50 seconds on the left. Patient treated by pilocarpine, and after a fortnight could hear a low voice at 1 foot on the right side, while the monochord was perceived up to 12,000. Now vestibular reaction was produced by cold syringing in 35 seconds. The left ear remained as before.

In this case, therefore, the ear which *gave no* reaction improved, while the other *did not*.

2. Wounded by shell explosion. Since then deafness and tinnitus in both ears. By each ear conversational voice heard at 1 foot. After 90 seconds of cold irrigation no nystagmus could be produced from either ear.

3. Shell burst in front of him, followed by immediate loss of hearing in both ears. Left ear improved, but not the right. Hears a loud voice

at 1 foot with the right ear and a distinct voice at the same distance with the left. No nystagmus resulted after 90 seconds' irrigation of either ear, and rotation also was without effect.

4. Blown up; was "blinded and unconscious" for 16 hours; afterwards found he was deaf in his right ear and that the hearing in his left "comes and goes." The right tympanic membrane was chalky and cicatrised, while the left was opaque. On the right a loud voice was not heard, while on the left a low voice was heard at 18 inches. Rotation from right to left and from left to right produced no nystagmus in either case.

5. Blown up by shell explosion; was stone deaf and had discharge from both ears immediately afterwards. The left ear has recovered slightly, but the right has remained completely deaf. The right membrane showed a large dry perforation, while the left was indrawn. By the right ear a shout was not heard, while by the left a distinct voice was heard at a foot. After rotation from right to left and left to right no nystagmus resulted in either case.

These five cases afford, in our opinion, definite proof that the vestibular reaction is of no decisive value in either diagnosis or prognosis. It will be noted that in the first it was the ear from which no nystagmus could be produced which recovered, while the others give ample demonstration of the fact that while vestibular reaction may be in abeyance the cochlear function may be more or less maintained. Whether we are to assume that the explosion was the cause of interference with the functions of the semicircular canals, or that for some reason the patients were defective in reaction, does not in the least affect the argument.

Group C.

In the following cases there is a history of head injury, and in them, therefore, we may assume that the evidence is in favour of organic rather than functional trouble.

1. Wounded behind left ear in August, 1915. Has suffered from deafness and tinnitus since; was very giddy at first. Hearing normal on right side, but by the left ear only a very loud voice near the ear was heard. Cold water produced nystagmus on the right side in 30 seconds and on the left in 15 seconds.

2. Shrapnel injury to right side of face; right ear has been deaf since. A shout was not heard by the right ear, while on the left hearing was normal. From both ears nystagmus was produced in 20 seconds by cold water.

3. Shrapnel injury to head, followed by deafness which has been getting worse; right auricle torn. By the right ear only a shout was heard at a foot, while on the left a whisper was heard at the same distance. Cold water produced no nystagmus from either ear after 120 seconds.

4. Wounded by bullet entering just behind left mastoid and coming out through the neck on the same side; not unconscious; noticed deafness a little later when trying to hear a watch. The hearing of right ear is normal, but on the left a very loud voice is only heard at a foot. Cold water produced nystagmus in 20 seconds on the right and in 40 seconds on the left.

5. Bullet entered left eye and came out one inch below the zygoma. Left eye shot out and blind in right eye when he regained consciousness. Marked deafness in both ears for some weeks. Left improved, but right remained deaf and was affected by tinnitus. The right ear was quite deaf, a shout not being heard, while the left heard a whisper at 1 foot, but there were symptoms of nerve deafness on this side (tuning-fork tests and monochord 9000 only being perceived). This case was examined nine months later, but the hearing remained as above. The vestibular reaction was exactly equal, cold water causing nystagmus in 32 seconds on each side.

6. Wounded in left cheek and blinded in left eye. Since has suffered from deafness in left ear and giddiness. While a low voice was heard at a foot by the right ear, a shout was not perceived by the left. Tuning-fork and monochord indicated complete nerve deafness on the left and partial on the right (11,000). Cold water caused nystagmus on the right side in 40 seconds and on the left in 30 seconds.

With the possible exception of Case 5, in which unfortunately the condition of the right eye does not seem to have been especially noted or inquired into, we may with reasonable certainty exclude all question of functional trouble. It will be observed that in Case 4 the vestibular reaction was better marked from the good ear. In Cases 1 and 6 this was, however, reversed, while in Cases 2, 3, and 5 the vestibular reactions were the same in both ears, varying from induction of nystagmus after 20 seconds of cold water (Case 2) to apparent extinction of vestibular reaction (Case 3), where after two minutes no result was obtained from either ear. It must also be noted that in this case one of the ears retained a good amount of hearing power.

Group D.

In the two following cases wounds were succeeded by middle-ear suppuration as well as nerve deafness.

1. Gunshot wound of face: bullet entered below right eye and came out behind right ear. Deafness and discharge on this side followed. The right tympanic membrane showed perforation and discharge, while the left was normal. By the right ear a shout was only just heard, while the hearing of the left was normal. Rotation from right to left and from left to right produced nystagmus lasting 16 seconds in each case.

2. Wounded by shrapnel on left side of neck and has been deaf since; was very giddy at first, but this has gone off. The left ear shows granulations and discharge, while there is a scar below the left mastoid. The hearing on the right side was good, but a loud voice was not heard by the left ear. Rotation from right to left caused nystagmus lasting 20 seconds, but that from left to right caused no nystagmus.

It will be noted that in Case 1 both vestibules reacted equally, but that in Case 2 that corresponding to the affected ear failed to respond. Are we, therefore, to conclude that Case 1 is suffering from hysteria or is even malingering, while we accept Case 2? As the results we have given seem to us to furnish absolute proof that the condition of the vestibular apparatus gives us no trustworthy guide to that of the cochlear, we must answer this question by an emphatic negative.

Conclusions.

While we have not been able to prove in any of the cases that we had to do with either functional deafness or malingering, we have shown that in Group A, where, perhaps, one or other of these conditions might be suspected, vestibular reaction was sometimes good and sometimes defective. Turning now to Group B, the first thing to be noted is that in the only case of partial recovery after concussion deafness we have met with, it was the ear in which vestibular reaction was absent which recovered. Again, the other cases of this series furnish ample evidence that vestibular reaction may be lost, while the cochlear functions are more or less active. In Group C we find unilateral deafness, the hearing in the other ear being good or fair. In only one of them was vestibular reaction more marked in the better ear; in two this was reversed and in the others it was equal. In one of the latter no reaction was obtainable from either ear, and yet the hearing power on one side was good.

From our experience and from analysis of the cases we have examined we conclude:—

1. That concussion deafness is generally due to some organic change.
2. That the prognosis is usually bad.
3. That the results of the vestibular tests can only be utilised in conjunction with information derived from other sources. Thus, if the patient shows other hysterical symptoms, vestibular tests may perhaps under certain circumstances help diagnosis; but to state that they do more than this is, in our opinion, misleading and dangerous.

GUNSHOT FRACTURES OF FEMUR:

SOME METHODS OF REDUCING SERIOUS DISPLACEMENTS.[1]

BY PHILIP TURNER, M.S. LOND., F.R.C.S. ENG.,
MAJOR, R.A.M.C.

TREATMENT of compound fractures of the femur on the Thomas's splint has been so generally adopted, and has so many advantages both as regards comfort of patients and easy performance of dressings with least amount of pain and disturbance of fragments, that the following remarks apply only to patients treated in this way.

Displacements.

"Serious" displacements will come under one of the following heads:—

1. Shortening.

This is often due to obliquity of fracture or to overlapping of main fragments. The most important way of overcoming these displacements is by efficient extension.

For over a year I have used steel springs to obtain extension in cases of fracture of long bones of leg treated on Thomas's splints. The springs used in ordinary spring mattresses answer quite well. When used for a mattress one end of the spring is naturally in the form of a hook, which can be slipped over the end of the splint, while the other forms a ring through which the extension bands can be threaded. (Fig. 1.)

If these bands do not pass round the side bars of the splint and are not attached to them none of the pull on the leg will be lost by friction. The actual pull exercised can be estimated by measuring increase in length of spring, having previously measured the lengthening obtained by pulling the mattress spring against a spring balance which has a dial showing amount of tension expressed in pounds. If small spring balances about four inches long can be obtained they may, as suggested to me by Lieutenant-Colonel Fairrie, R.A.M.C., be used on the splint instead, and the amount of tension at any time can be seen at a glance.

Springs are easily attached and have distinct advantages over other methods of obtaining extension.

[1] Abstract of a paper read before the Tréport Medical and Surgical Society.

Spring extension is easily applied, usually little or no readjustment is required, and any pull up to 15 lb. can be obtained or more if thought necessary, though this is rarely called for.

2. Rotation.

One of the drawbacks to the Thomas's splint, both for arm and leg, is that rotation of the limb may take place after the splint has been applied. A simple and effective method of preventing rotation, or of fixing the leg in any degree of rotation which position of fracture renders desirable, is that brought forward by my colleague, Captain H. M. Anderson, R.A.M.C. This consists in the use of two small lateral supports, about 4½ in. by 3½ in., cut from a sheet of Gooch's splinting. These supports are made in pairs, and to each two tapes and buckles are fastened by a couple of drawing-pins. If the tapes of one are fixed near the centre and of the other near upper and lower margins they will clear one another during fixation.

These supports are held against the lateral aspects of the leg which is in the desired position, either at level of knee or just below it, a jaconet-covered pad of gamgee tissue rather larger than the support being placed between each and the limb to avoid pressure. The tapes are now passed behind the leg and beyond opposite bar of splint and are then securely fastened by buckles. Not only is rotation prevented, but the limb is also more securely attached to the splint.

Generally speaking, the leg should be fixed with a slight degree of external rotation. The lateral supports should not be applied until after the extension has been obtained. The supports and their mode of application are shown in Fig. 1.

3. "Sagging."

This is a deformity all too frequently seen. It may occur with fractures of any part of shaft of femur, but is especially common in fractures of middle and lower thirds. Sagging

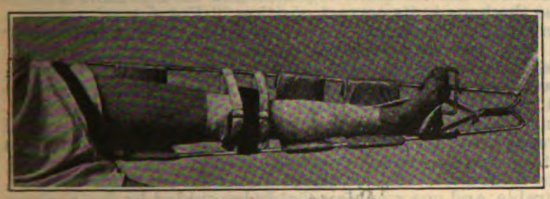

FIG. 1.—Illustrating the method of obtaining extension by a steel spring and the lateral splints for preventing rotation. The tapes attached to the outer of the two small lateral splints are coloured black.

may sometimes be prevented or remedied by careful attention to adjustment of supports which suspend thigh from bars of Thomas's splint. These should be brought as near the wounds as possible, and if removal for dressings is necessary support should be given, if possible, by temporary sling of gauze. Not infrequently, in spite of all care and attention, a certain amount of sagging will occur.

Sagging is likely to produce serious permanent disability. It is commonly associated with some lateral displacement of the main fragments.

4. Displacements of comparatively small fragments at the ends of the bone to which powerful muscles are attached.

These displacements may be very difficult to rectify, especially where there is much comminution and severe septic infection, and there is then a great probability of mal-union and a bad functional result.

(*a*) If at the upper end of shaft a fracture should occur just below the small trochanter the small upper fragment will be flexed by action of ilio-psoas and abducted and externally rotated by action of muscles attached to great trochanter. The upper end of the lower fragment will be behind and to the inner side of the upper, and is also displaced in an upward direction, a position, in all probability, largely due to the weight of the limb.

(*b*) When the shaft of the femur is fractured in its lower third just above condyles the lower fragment is generally displaced and rotated backwards, sometimes excessively so.

[The usual methods of treatment were criticised and causes of failure pointed out.]

Treatment by Direct Wire Suspension and Traction.

The great difficulty of rectifying the displacements described above, especially in the more severe and complicated cases, suggests the desirability of some method of mechanical fixation applied directly to the fragments rather than to the limb.

Plating of recent septic gunshot fractures has been condemned, and, I think, rightly so. Even in the late stages of treatment after mal-union the extensive disturbance of soft parts necessary and the denudation of periosteum from a large area of bone are liable to be followed by a renewed outburst of severe septic infection.

I have recently treated a number of cases in which "sagging" was present to a marked degree, and of fractures of upper and lower part of shaft with typical displacements already described, by a method in which the straight Thomas's splint and the ordinary methods of obtaining extension and preventing rotation are used, and which can be employed in conjunction with any method of suspending or supporting the splint. The principle of this method, which has been called "wire suspension and traction," is that a loop of silver wire is manipulated round the free end of the displaced fragment, which is then pulled into position, and maintained so by attaching the wire to a rigid arch passing over the limb between the two bars of the splint.

Before employing this method a careful examination of stereoscopic X ray plates, or of plates showing the fracture in two planes at right angles, is essential.

The position of the fracture, nature and extent of displacement, and amount of comminution must all be determined, for upon these points will depend the shape and kind of loop required, whether one or both fragments will require suspension, and also direction of pull necessary to maintain fragments in position.

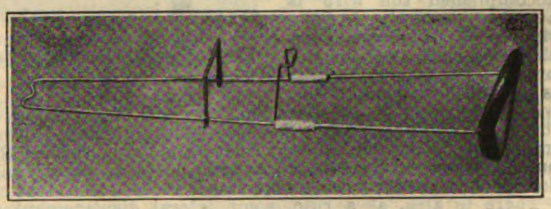

FIG. 2.—A Thomas splint with two arches for wire suspension attached. To the right is a standard pattern foot-piece fixed in position by strapping. To the left a specially made arch with holes and notches is screwed to side bars of splint.

Three types of rigid arch have been tried.

1. A strip of aluminium splinting is bent into suitable shape. A thin strip of metal is on each side passed through the notch opposite side bar of splint and is fixed to this by strapping. This is not sufficiently firm and soon allows some movement of the arch and so of the wire.

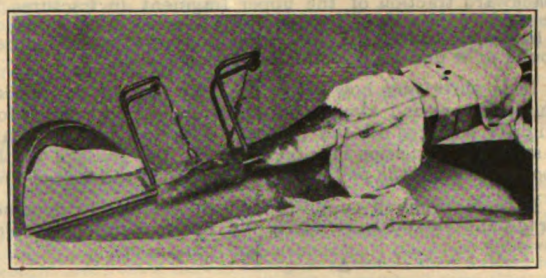

FIG. 3.—A septic comminuted fracture near middle of right femur. There was much sagging with backward and inward displacement of lower fragment. Wire suspension to each fragment, the lower being drawn forwards and outwards, the upper forwards and inwards. The ends of the loops project beyond the wound.

2. One of the standard pattern supports for the splint often employed as a foot-piece can be widened and altered so as to fit the splint at any point, and is then fixed by strapping. (Fig. 2.) These are perfectly firm, and answer very well, but as there are no holes or notches the wire is apt to slip unless the support is fitted exactly in the right place.

3. Special arches can be made so as to screw on to the side bars, and are provided with holes or notches through which the wire can be threaded. (Fig. 2.) Though most useful, these are not essential.

If it is thought desirable that one of the displaced fragments shall be pulled backwards (traction) the arch can be equally well fitted to pass behind the leg.

Method of Application.

The splint is first put into position, supports are arranged, and strong extension is obtained by a spring.

The limb is now held so that the foot shows a position of slight external rotation, and the lateral supports which control rotation are applied. Both the extension and lateral supports can be readjusted, if thought necessary, after the wire suspension has been carried out.

The wire employed is ordinary silver patella wire.

Where there is an oblique fracture, or where the comminution is not severe, the end of a suitable length of wire may be twisted to form a loop. The ends of the fragments are usually already denuded of soft parts, and can be felt by a finger in the wound. The wire loop is then introduced and with the help of the finger is insinuated round the free end of the displaced fragment. In the event of the free end of the fragment not being sufficiently exposed a periosteal elevator may be used to clear it for a short distance, but extensive baring is neither necessary nor desirable.

The displaced fragment is now pulled up into position, and when the finger shows this to be satisfactorily accomplished the wire is attached securely to the rigid arch which has been sterilised and fixed in the proper position. If the pull is made obliquely and if the wire is fastened in this direction there will be no danger of the loop slipping off—i.e., if a backwardly displaced lower fragment of a supracondyloid fracture is being treated the pull should not be straight forwards but also slightly in a downward direction towards the knee.

There is also, as a rule, some lateral displacement of the fragments, the upper being abducted and the lower adducted. This must also be taken into consideration when drawing the fragment into position and fixing the wire. Generally speaking, in fractures of lower and middle thirds of shaft of femur the attempt should be made to draw the lower fragment into line with the upper, and hence the single wire around the lower fragment will, as a rule, be sufficient.

In some cases of sagging, however, where the upper fragment is abducted and the lower adducted or the reverse excellent alignment may be obtained by two wire loops, one drawing the lower fragment forwards and outwards and the other the upper fragment forwards and inwards. (Fig. 3.) Backward traction of the upper fragment in fractures in this region is seldom required, and in a few cases in which I have employed it in this region the wire has soon been found to be unnecessary and has been removed.

It is surprising how often the wire can be introduced through a wound already present, this being, if called for, slightly enlarged in the required direction. If necessary a small fresh incision may be made for the passage of the loop or to allow the pull of the wire to act in the correct line.

If there is much comminution all completely detached fragments should be removed and the wire or wires should pass round the extremity of one or both main fragments, including, if possible, any large piece of bone which is not quite loose.

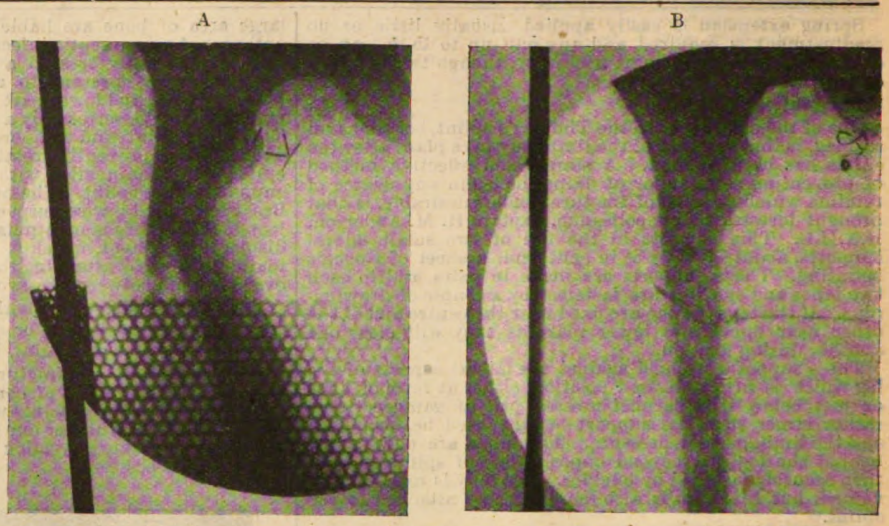

FIG. 4 (Case 3).—Fracture of right femur. A, Position when sepsis had subsided; B, after wire traction of upper fragment.

In some comminuted fractures it may be possible to pass a wire round all the fragments and cross the wire again in front so as to bind them together and at the same time to raise the bone to its correct position. (Fig. 5.)

In the case of fractures below the small trochanter the question will arise as to whether a loop should be used to draw the upper fragment backwards and inwards, or whether the lower fragment should be drawn forwards and outwards into line with the upper and smaller fragment. If the former procedure be adopted the wire will have to pass through the adductors and to be attached to a posterior arch or to a support attached to inner bar of splint. It is difficult to say which of the two methods is most desirable, and one would probably be guided by the position of the wounds, the amount of displacement, and which fragment was the more accessible. So far I have only treated two fractures in this situation by wire suspension, one by each method, and in each the result has been equally satisfactory. (Fig. 4.)

Efficient drainage having been secured attention is directed to the extension, and, if necessary, the spring and the lateral supports are readjusted. The supports beneath the thigh should also be tightened up so as to raise the soft parts and take some of the weight of the limb off the wire. It may here be pointed out that after sagging of the fragments has been corrected there may be a sagging of soft parts due to œdema and the dropping back of muscles and soft tissues which gives a very similar outline to the thigh, though an X ray examination may show a perfect alignment.

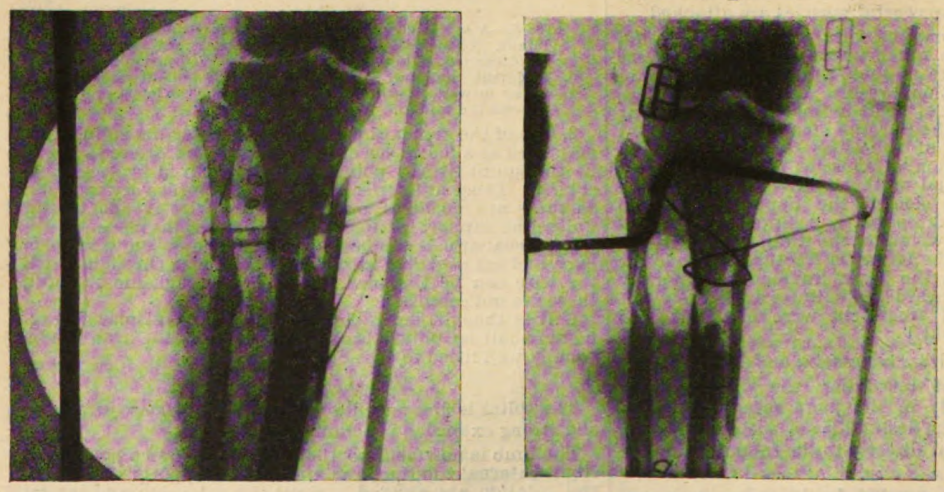

FIG. 5 (Case 5).—Fracture of right tibia and fibula. A, Before treatment; B, after wire suspension. The outline of the large wound can be seen.

Removal of Wire: Advantages of Method.

The presence of the wire causes no irritation or increase of sepsis.

Indeed, as a rule, the fixation of the limb in good position is attended with improvement in wound and in general condition of patient. There is no pain even when, as sometimes occurs, the wire cuts a little into the soft tissues. Needless to say, care must be taken that the wire does not press against nerve trunks or against large vessels, and in the lower part of the thigh the presence of supra-patellar pouch

of knee-joint must be remembered. Fortunately in this region the wire has to be usually brought out well to the side of the limb. After a week or ten days a further X ray examination should be made, and if necessary the wire can be readjusted.

The shortest time the wire has been left in position is two weeks, and in this case, where there was some cutting into the muscle and a little oozing of blood, there was no recurrence of the displacement. It is better to allow three or four weeks, or even longer, to elapse before removing the wire, as its presence causes no trouble; in one case it was left for eight weeks. The amount of bone lost and the radiographic evidence of union will guide one as to the advisability of removal. If the ends of the loop can be seen the wire may be cut and pulled out at an ordinary dressing, but if out of view in the deeper part of the wound nitrous oxide anæsthesia will be desirable.

Wire suspension can also be employed for suitable fractures of the tibia and fibula, especially where there is much comminution with large posterior wounds and sagging of the leg. It might also be of use in some fractures of the humerus.

Though in some cases wire suspension can be carried out with advantage as soon as the patients are admitted to a general hospital, as a rule it should be left until the acute infection has been overcome and the swelling has subsided—i.e., during the second stage of treatment and as early in this stage as possible.

I have recently employed the method in a very troublesome case of non-union of a fracture of the lower third of a shaft with backward rotation of the lower fragments five months after the injury, where several previous attempts by other methods had been made and failed, and after four weeks the fragments are still in good position.

The chief advantage of the method is its simplicity.

No special apparatus of any sort is required, for the ordinary foot-piece fixed over the splint is a perfectly efficient support. The actual operative interference, division of soft tissues, &c., is always slight and in many cases is literally nil. The kind of loop used and the arrangement of the wire will depend on the necessities of each individual case. The ordinary Thomas's splint is used and any method of dressing and treating the wound can be employed.

While fully admitting that there are other ways of effectively treating these displacements, I venture to bring this forward as a simple method which is of the greatest service in some very troublesome cases.

Illustrative Cases.

CASE 3 (Fig. 4).—Lance-Corporal G.P.K., aged 30, admitted Oct. 31st, 1917. Metal fragment removed before admission. Very septic wound, much swelling 5 inches long on outer side of right thigh in upper third. X ray showed oblique fracture sloping downwards and outwards from small trochanter for 3 inches.

Nov. 1st: Anæsthetic; wound opened up and spring extension applied. Pyrexia and sepsis persisted for a long time, though drainage appeared satisfactory. By end of December improvement had taken place in these respects, but the fracture was obviously in very bad position, upper fragment being very flexed and abducted, so that lower fragment could be felt passing upwards to inner side of, and behind, the upper. X ray examination showed these points clearly. (Fig. 4 A.) Fresh extension was applied and leg held in fully flexed and abducted position, but X ray examination showed only slight, if any, improvement.

Jan. 12th, 1918: Anæsthetic. Wire loop placed round free end of upper fragment. Counter incision made in adductor region and wire brought out through this and upper fragment pulled backwards and inwards into line with lower. Wire fastened to inner bar of Thomas's splint.

On Jan. 20th X ray examination showed perfect alignment. (Fig. 4 B.) Little pain and no increase of sepsis, but on 30th, as there had been a little oozing of blood from the inner wound the wire was removed. After this patient did well and an X ray on Feb. 20th showed that there was no recurrence of displacement.

Discharged to United Kingdom March 1st, wounds nearly healed, firm union, no obvious deformity. Shortening ¾ inch.[2]

CASE 5 (Fig. 5).—Private A. P., aged 25, admitted Jan. 5th, 1918, with compound fracture of right tibia and fibula. Large wound on outer aspect of leg, 5 by 3½ inches, which had been freely excised at C.C.S., anterior tibial vessels having been ligatured. Wound very septic; severe comminuted fracture of tibia could be seen. The main lower fragment was displaced forwards 1½ inches in front of main upper fragment. In addition several large fragments not completely detached were projecting into wound at various angles. (Fig. 5A.)

Jan. 6th: Anæsthetic; leg put up on Thomas's splint with spring extension taken from plaster-of-Paris anklet. A wire was insinuated under fracture and ends crossed in front of tibia and each attached to arch. As wire was tightened the various fragments came together and the bone was reconstituted except for a piece which had been blown away or removed. (Fig. 5B.)

Though the position was, and continued to be, excellent, the septic process advanced and skin and soft tissues below wound became gangrenous, probably as result of ligature of anterior vessels. As there was considerable pyrexia with delirium and sévere toxæmia the leg was amputated on Jan. 11th, but a stereoscopic X ray examination taken just before showed that position of fractured tibia was practically perfect, and that fibula had also come into position. The operative interference for introducing the wire was practically nil and was not the cause of the sepsis or the gangrene which occurred some distance away.

[2] All measurements are taken from anterior superior spine of ilium to tip of internal malleolus, tilting of pelvis being corrected, both legs being in same position of flexion, abduction, and rotation.

I have to thank my colleagues, Captain H. M. Anderson, R.A.M.C., and Lieutenant E. L. Councell, R.A.M.C., for their coöperation and help in treating these cases, and Captain M. H. Watney, R.A.M.C., for many radiographic examinations and photographs.

TREATMENT OF FRACTURE OF THE SHAFT OF THE HUMERUS BY SPLINTS.

BY CHARLES A. MORTON, F.R.C.S. ENG.,

PROFESSOR OF SURGERY, UNIVERSITY OF BRISTOL; SENIOR SURGEON, BRISTOL GENERAL HOSPITAL, CHILDREN'S HOSPITAL, AND BEAUFORT WAR HOSPITAL; MAJOR, R.A.M.C. (T.)

Need for Fixation to Chest Wall.

THERE is only one way in which a fracture of shaft of humerus can be absolutely fixed, and that is against the chest wall. I have for many years recognised this, and treated such cases by first fixing a splint to side of chest and then the arm on it, or fixing the arm on splints and then fixing these splints to side of chest.

Early in 1917 I treated a case of gunshot fracture of humerus; portion of shaft absent, leaving gap of 1 inch and flail-like arm. After wound had healed arm was so wasted, with ends of bones so prominent, that one quite easily detected any movement. By most careful fixation of limb on an internal angular splint, and of splint to chest wall by strapping, I could not control all antero-posterior and rotatory movements at seat of fracture—indeed, they were possible to quite a marked extent.

It seemed that only fixation by plaster-of-Paris to chest could absolutely fix fragments. I fixed internal angular splint to side of chest with plaster, and then arm and forearm to splint. This gave absolute fixation of fracture. Patient had musculo-spiral nerve paralysis, and it was important to leave extensor aspect of forearm free for massage and electrical treatment. This was easily done, because fixation simply of elbow and wrist on internal angular splint, fixed securely to side of chest, was quite sufficient absolutely to fix the fracture.

After treating the case in this way I was interested to find that Erichsen had held very strong views[1] as to the need for fixation to the chest wall. He recommended fixation by plaster-of-Paris bandages.

[The way in which the fractured ends are often displaced by the position in which the forearm is placed after splints are applied was described.]

Correct Angle for Forearm in Relation to Body.

When the arm lies at rest by the side the intero-anterior surface lies against chest wall—i.e., anterior aspect of elbow does not look directly forwards, but also inwards.

If elbow is flexed the forearm will project forwards at an angle of about 67° (or three-quarters of a right angle), with a plane representing anterior surface of body. Some surgical writers say it should be flexed at a right angle to such a plane, but this means slight rotation out of lower in comparison with upper fragment. If the flexed forearm is brought over front of chest in a sling, as is so often done, rotation *in* is quite marked and the elbow is brought forwards at same time, and upper end of lower fragment displaced backwards and outwards.

The difference between fixation of forearm at 90° and 67° with anterior plane of body is not very serious, but the latter is preferable. If an internal angular splint is used (and this certainly seems to give the best fixation in fracture of shaft of humerus, for it is essential to fix elbow), this angle can only be obtained by having forearm part of splint fixed at an angle of 22° to plane of arm part of splint; this will fix forearm at angle of 67° with anterior plane of body.

Advantages of a Posterior Splint.

If we use the combination of a posterior and an internal splint, fixed together and fixed by plaster to the chest, we provide a stable support for the arm when the patient is sitting up or lying down.

Anterior or outer splints can be added, if thought necessary, and fixed by webbing straps or strips of strapping. The posterior and internal splints should be joined by quite small nails or by quite narrow strips of thin metal, so that no metal lies behind fracture to obscure skiagram. In certain cases hinges might be used, but to unfix a splint for a dressing is never satisfactory.

But if posterior splint is not fixed to internal one in construction of splint it must be fixed to it by firm strapping carried round internal splint on which arm rests, through triangle, and not round patient's body. But it is a decided advantage to have it fixed in construction of splint, especially when we have to place fractured arm on splint in recumbent position (as under an anæsthetic).

I do not think it is needful to carry the posterior splint higher than it is possible to do the internal one, so as to support the upper fragment behind.

[1] Erichsen's Surgery, 1895 edition, p. 590.

The construction of the splint allows a lateral skiagram to be taken. (Fig 1.)

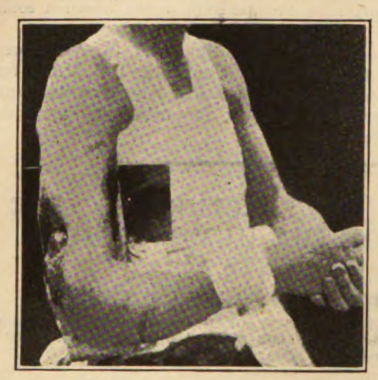

FIG. 1 shows splint fixed to chest wall with plaster bandages. The wrist is fixed to splint with piece of strapping. A skiagraphic plate has been inserted through the triangle to show how a lateral skiagram can be taken with the arm securely fixed to the chest wall. A large gunshot wound on outer aspect of arm is shown. The splint is my original one without a posterior part.

Other Details in Construction of Splint.

The base of triangle should be 4 inches, so as to give a sufficiently large angle at upper end, and this angle must not be filled in. The two pieces of wood which form sides of splint must be so bevelled that junction at upper angle is an angle and not a flat surface, for if it were the fragment might be displaced outwards by thickness of splint at upper angle. (Figs. 2-4.)

The average length of part of splint on which arm rests (outer side of triangle) should be 10 inches (about average length of arm from anterior axillary fold to lower border of bent elbow). In a very short man it was 9 inches, and in a man 6 feet 1 inch it was 11 inches.

If possible it would be best to take exact measurement for construction of splint, but a 10-inch splint would be right for most cases, and if not it would only necessitate fixing forearm either slightly over or under edge of forearm part of splint, and even in a 9-inch arm would adequately support elbow.

But if splint is not made from measurement the forearm part need not be fixed to arm part until it is used. It can then easily be screwed on to it, and will do for either right or left forearm. The triangular part of splint can then be made of full length—11 inches—and forearm part can be screwed on at any level.

Question of Abduction of Arm.

There is no objection to placing the limb in the abducted position if both fragments are equally abducted.

Indeed, in fracture below insertion of deltoid it is a distinct advantage, for the upper fragment is abducted by that muscle.

Some surgeons recommend abduction for treatment of fractures of urgical neck. Even granting that upper fragment may be a little abducted by supraspinatus, it certainly cannot be much, and if we markedly abduct the lower fragment when there is no abduction or only very slight abduction of the upper we shall get angulation at seat of fracture.

It therefore seems to me a great mistake to put up a fracture high up in shaft of humerus (i.e., a fracture higher than an inch below surgical neck) in such extreme abduction as a right angle with the body.

Treatment of Fractures Very High Up in Shaft of Humerus.

We cannot control position of upper fragment of a fractured humerus by a splint, unless it is more than one inch below surgical neck. In such cases the triangular splint cannot be used, for it would abduct lower fragment and could not abduct upper. I think it should be a rule in treating fractures of humerus not to abduct lower fragment unless you abduct upper fragment also, or a skiagram shows that it is abducted. In these cases, of course, no plate can be placed high enough to obtain a lateral skiagram, unless just for a very brief period it pushes up anterior axillary fold.

If the fracture is at this high level we must be content to fix arm in intero-posterior splint with forearm projection, fixed by plaster bandages against chest wall, but the splint must be made of quite thin wood and upper end must be carefully bevelled, so as not to push out lower fragment into abduction, particularly at upper edge, or to abduct upper by pressure of edge against lower end if it reaches high enough to lie just inside lower extremity.

If we have a posterior splint fixed to an internal one, as I think we should, we cannot carry our turns of plaster bandage around internal splint and chest wall unless we have posterior splint interrupted. It will be enough to have two gaps in it, to carry plaster bandages through, to allow of firm fixation to chest wall. In the triangular splint plaster bandages pass through triangle.

In these high fractures without wounds it might be enough to fix arm to side of chest with plaster bandages, but I think a splint is more satisfactory. To simply fix arm against side of chest with strapping or bandages seems quite unsatisfactory.

Extension can easily be applied by carrying side of triangle on which arm rests, or internal splint if no triangle is used, a few inches beyond fracture with forearm projection, and fixing a small piece of wood or metal at right angle to end, and attaching to this a rubber accumulator or spring.

[The treatment of gunshot and other compound fractures of the shaft of the humerus and the modifications in the form of splint required by them were here dealt with.]

Method of Applying the Splint.

The splint is best applied with patient standing, or sitting on stool; he should hold his body as erect as possible and keep shoulders level. I think it would be very difficult to apply plaster bandages in recumbent position. But if any operation on the arm is required when fixed on splint it is not necessary to remove plaster fixation of splint to chest, as it does not fit tightly, but it would be well to cut it through in front with plaster cutters and then put a bandage around it in case of any need for artificial respiration. The plaster case can be made perfect again the next day by a few plaster bandages. If it is necessary to give an anæsthetic to fix the fracture for the first time on the splint, the best plan is to temporarily fix the splint to the chest wall with a binder over it. The whole chest must, of course, be covered with flannel bandages, or a thick vest put on before the splint is fixed to it with the binder.

During the time the splint is being fixed to chest wall with plaster bandages the fractured arm must be very carefully supported on an internal angular splint in abducted position by a nurse or orderly, who give their whole attention to this. And before fractured arm is raised into abducted position the exact level to which upper edge of splint is to come should be marked on chest wall.

The splint is padded on both sides. Several folds of lint (boracic lint is best) are quite enough, and no great thickness must be used between chest wall and splint, nor is this necessary on arm aspect of splint. Upper angle of splint must not be thickly covered.

In applying plaster bandages it is well to take a few turns under splint—i.e., under base of triangle, and over opposite shoulder protected with a thick pad of lint, to hold up splint well. As soon as plaster bandages have set enough to fix splint to chest wall the fractured arm is placed in good position. All that need be done in way of permanent fixation is to secure forearm on forearm splint with pieces of spool strapping around forearm just above wrist and the splint; this fixes elbow and with it lower fragment.[2] The forearm is placed on splint in semi-pronation and need not be covered on extensor aspect (except for one inch above wrist by strapping), so that it is available for massage and electrical treatment in lesions of musculo-spiral nerve. If there is a lesion of this nerve forearm part of splint should extend beyond wrist to allow of hyperextension of that joint; but if no lesion of musculo-spiral nerve it should not be long enough to interfere with wrist movements.

The internal and posterior splints will prevent any angulation at seat of fracture in these directions, and if there is a tendency to it in anterior or outward direction extra splints can be added on either aspect and fixed by webbing straps or strips of spool strapping passed through angle. If triangular splint is not used but the straight one, it is well to place the webbing straps between splint and chest wall before fixing with plaster bandages, so that they may be available for extra splints if required.

If desirable the elbow can also be fixed by a narrow piece of strapping carried obliquely over it and under lower end of internal splint, through triangle, or round arm aspect of upper end of forearm splint where it joins arm portion, if a splint without triangle is used, but this fixation of the elbow is not essential. It is desirable to support forearm portion of splint until plaster has quite set, so that weight of forearm does not drag splint out of position.

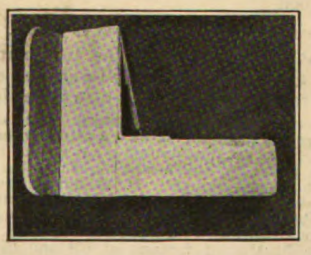

FIG. 2.—The splint I now use. On the left is seen posterior portion attached at right angle to internal portion, which forms one side of triangle, and on this the arm rests. Another side of the triangle—that attached to side of chest—is just seen behind it. The forearm part of splint is seen projecting to the right, from the internal part.

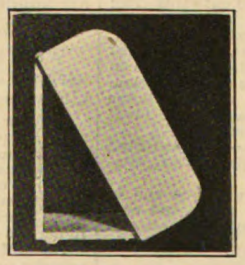

FIG. 3.—The splint, showing the triangle, and a back view of posterior part of splint, which hides internal part on which arm rests. The straight side of the triangle, which is seen in the figure, is fixed to the chest wall.

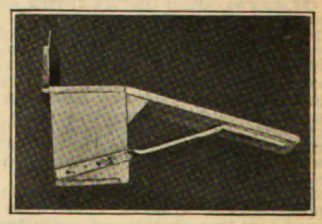

FIG. 4.—The splint viewed from its under aspect to show angle (22°) at which forearm piece is attached to internal piece. The part of the splint to which the metal bar supporting forearm piece is attached is the base of the triangle. This metal bar is not essential. On top of the splint is seen lower edge of posterior piece of splint.

[2] This is all that is absolutely necessary, but I generally put strapping or bandage around the arm as well.

Other Forms of Splint which are Fixed to Chest Wall.

I wrote the first part of this paper in the early part of 1917, but did not complete it until I had had further experience in the treatment of these fractures of the shaft of the humerus.

In the meantime I know that three papers have been published (and probably several more have been which I have not seen) in which splints are described which are fixed to the chest wall.[3]

Captain Wilson advocates fixation of splint to chest wall by plaster bandages, but I should prefer my own splint. I think the arm would be more securely fixed on it than on a rod-and-sling splint, and I do not consider the arm should be brought across the chest.

I should have the same objection to Mr. Pringle's splint—i.e., that the lower fragment is rotated in or out by position in which forearm is placed, and I also see no reason why abduction should be carried to such an extreme as to make it very awkward for the patient to get about when able to do so.

The wire frame method of fixation to the chest wall advocated by Captains Johnston and Buchanan does not seem to me nearly as secure a method of fixation as plaster bandages.

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The Cavendish Lecture on the Future of the Medical Profession.

A MEETING of this society was held at the rooms of the Royal Society of Medicine on July 11th, Dr. A. J. RICE-OXLEY, the President, being in the chair, when Major-General Sir BERTRAND DAWSON delivered the second part of the Cavendish Lecture (see p. 83). In the discussion which followed,

Major HENRY DUTCH drew attention to the difficulties of accommodation in the case of hospital clinics. In a suburb of, say, 80,000 there would be about 40 doctors. Each would need his own consulting-room and his own waiting-room. A union of medical men was required, ready to uphold each other and stick together.

Major Sir JOHN BROADBENT said that the greatest drawback to the out-patient centre was that every doctor in the district could not be put on, and those who were not would feel themselves severely ill-treated. All classes of patients would not attend the centre at a fixed time as this would mean a mixed crowd of poor and rich. It was necessary to know the home life of the patients in order properly to deal with diseases, and besides a certain number must be attended to at home. He thought the better plan would be to establish centres in different parts of London, to which specialists (including radiographers, pathologists, &c.) should be attached, and to which the general practitioners could bring their patients and have advice free. At present it was difficult to get such help. Poor people should be attended at the expense of the State, but those attending them should have adequate remuneration. The hardest case was that of the middle class. Attached to the voluntary hospitals there should be paying wards admitting patients according to their means. He disapproved of putting the hospitals under the State or University.

Dr. E. H. M. STANCOMB (Southampton) said that the general practitioner should be educated thoroughly in public health, housing, and town-planning. He should have a full knowledge of local hygiene, especially that of his own town.

Captain W. F. H. COKE asked if the whole population were to come into the scheme. He thought the practice of the country doctor must be essentially as it was to-day, but he should have the assistance of a special opinion when needed.

Major GORDON DILL said that the only people who could reap benefit from our present system of treatment were the very poor and the rich, the latter at great trouble and expense. The resources of medicine should be free to all. The period of gradual change had become a revolution owing to (1) the Insurance Act and (2) the war.

Captain A. E. RUSSELL said the first thing to decide was whether the principle of the scheme was accepted—whether the profession was satisfied with some form of State control. What means were available to bring evidence to show that the profession supported it?

Dr. G. E. HASLIP said that we must look at the matter from the point of view of the health of the nation and make the people of the country healthy, which the present system did not do. Prevention was not considered enough by the profession. The country was governed by permanent officials and not by Parliament. The Ministry of Health Bill was blocked and Parliament was helpless.

Sir ROBERT MORANT said that medical men must take more part in public affairs. At present the Maternity and Child Welfare Bill was being passed through Parliament without any organised assistance or advice from the profession as to how the problem should be handled. The medical profession had no right to say that things were thrust upon them from above when they did not think things out for themselves. It was impossible to get matters properly voiced by the profession. They should get to work to decide as to the particular characteristics the scheme should possess.

Mr. F. G. LLOYD also spoke, drawing attention to the various forms of State service already in existence, such as the Royal Army Medical Corps, the Royal Navy Medical Service, the Indian and Colonial Medical Services, and Sir BERTRAND DAWSON briefly replied.

Reviews and Notices of Books.

ELMSLIE, M.S., F.R.C.S., Major, R.A.M.C. (T.F.), Orthopædic Surgeon to St. Bartholomew's Hospital, Surgeon to Queen Mary's Hospital, Roehampton. With 208 illustrations. 1918. Pp. 160. Price 6*s.* net.

London: University of London Press, Ltd.
Paris: Masson et Cie.

I. THIS volume is based on Professor Lagrange's experience of over 2500 wounds involving the eyeball inflicted in the present war, including 609 cases of fracture of the orbit. From this material a selection of case-histories is given and analysed in such a way as to make the work one of value, not only from the standpoint of general as well as ophthalmic surgery. The following examples of original deductions drawn by the author will serve to give an idea of the scope of his work.

Indirect fractures extending from the vault of the cranium to the sphenoidal fissure and involving the orbit should, according to the classic authorities, form a prominent feature in the practice of war surgery, but as a matter of fact these cases are exceedingly rare. In only two out of 609 cases was a fracture of the orbit so caused.

When a projectile passes above the orbit, implicating the frontal bone and the anterior cerebral region, it produces fractures of the orbital vault affecting the sensory, motor, and optic nerves in the region of the optic foramen and the sphenoidal fissure. The eyeball is not involved. ..... When the projectile passes below the eyeball without traversing the orbit and without fracturing it, it produces concussion affecting the eye in the macular region. This is the great cause of diminution or loss of acuity of central vision.

The author's explanation of the frequency of macular lesions in these cases is interesting. The violent air-vibrations caused by the projectile are propagated, he points out, to the orbital contents by way of the pterygo-maxillary fossa and spheno-maxillary fissure; the wave of oscillation tends to toss the eye forwards while the optic nerve holds it back. In this disturbance the fragile macular region at the posterior pole is the most apt to suffer.

Some new light is thrown on what has always been a somewhat obscure subject—viz., hæmorrhage into the sheath of the optic nerve. In no single case in which this condition was presumably present did Professor Lagrange find the ophthalmoscopic picture of retinal ischæmia, and he is therefore inclined to agree with Gonin and Dupuy-Dutemps, who reject this as one of the causes of that condition. Another

observation worthy of note concerns what the author terms traumatic proliferating choroido-retinitis, a condition resulting from hæmorrhage after laceration of the retina and choroid, to be distinguished from ordinary retinitis proliferans, in which the origin of the blood clot is spontaneous hæmorrhage into the vitreous without the implication of the choroid at all.

Among other subjects on which this book throws light we may mention traumatic detachment of the retina (four cases are given where detachment was due to concussion without direct injury to the globe) and traumatic enophthalmos. With regard to the treatment of these serious cases there is not so much said that is new. Professor Lagrange's experience of the rarity of sympathetic ophthalmia agrees with that of all others who have written on the subject during the present war. At the same time he insists that it would be a fatal mistake to ignore the danger, and, while giving rules on the subject similar to those generally taught, lays especial stress on the importance of the earliest stage of the infection. "We say without hesitation," he writes, "that photophobia, lacrymation, fatigue in reading and diminution of visual acuity are the first degree of the affection of which serous iritis is the second degree, and of which iridocyclitis is the third." A chapter on reparative surgery of orbital fractures gives some interesting hints about that difficult subject, restoration of the eyelids, especially about the employment of adipose and cartilaginous grafts, though the size of the book does not allow of these matters being very fully dealt with. We commend the book as concise, interesting, and original. It is very well translated.

II. To assist the surgeon to devise the most suitable apparatus for the individual case of the maimed man who has to be provided with an artificial limb this little book by Professor Broca and Dr. Ducroquet is admirably adapted. The methods used in France are in many respects different from those employed in this country, and the surgeon will find here a greater choice of the most suitable apparatus.

Blood Pictures. By CECIL PRICE-JONES, M.B. Lond. Bristol: John Wright and Sons, Ltd. 1917. Pp. 91. Price 6*s.* 6*d.* net.

THIS little book was written, so the author tells us in his preface, in response to the frequent request by clinicians for some guide to the interpretation of reports on blood examinations, and also for some simple method by which general practitioners can assist diagnosis by making blood examinations. Many general practitioners will welcome this practical answer to the request. The study of the cellular elements of the human blood under conditions of health and disease has received the attention of the best brains amongst medical scientific men in every civilised country of the world during the past 20 years or more. The existing literature on the subject is immense and in its manifold difficulties and complexities the subject is one which may well occupy the whole attention of an expert worker for a life-time. For this very reason, and for the fact that quite definite assistance may be derived from total and differential examinations of the blood cells in many cases, it is opportune that such a guide as the one under review should have come into being. With its aid the general practitioner should be able to appreciate the value of cellular hæmatology in the differential diagnosis of human diseases, especially as the author has not unduly emphasised the reliance which may rightly be placed on laboratory examinations by those in need of general guidance. After defining the normal red and white cells, their types and total and relative numbers in the human blood, the author proceeds to a description of the blood pictures found in bacterial, protozoal, "blood," and malignant diseases. In each case he gives examples of actual cases occurring in his own experience, which serve as illustrative types of the particular picture. The book is well arranged, is agreeably dogmatic, and presents the subject in lucid form. We cordially recommend it to those for whom it was written.

Three Clinical Studies in Tuberculous Predisposition. By W. C. RIVERS, M.R.C.S., D.P.H., Tuberculosis Officer, Barnsley District, West Riding, Yorks. London: George Allen and Unwin, Ltd. 1917. Pp. 272. Price 12*s.* 6*d.* net.

TUBERCULOSIS is a medico-sociological problem the intricacies of which seem to increase in complexity as investigations become more penetrating. There is much still to be learnt regarding the nature, varieties, and conditions of the growth of the tuberculous seed, but in regard to the tuberculous soil we are still merely scraping the surface of things. Dr. Rivers has accomplished a valuable purpose in gathering together into one volume the results of his personal observations and researches regarding certain physical conditions which can be conveniently viewed as predisposing to tuberculous infection or influential in the spread of tuberculous lesions. The first part deals with the supposed relationship between consumption and ichthyosis. The author's conclusion is thus rather curiously summarised:—

"In all three ways, then—from a penetrable skin, especially from diverse internal anomalies, possibly sometimes from naturally feeble constitution—if not in others as well (for the "efficient cause" oftener comprises a plexus of antecedents than it presents only one), existence of ichthyosis may entail liability to consumption. There is thus something of an *a priori* case, which, added to the direct clinical evidence given first, establishes to one judgment at least ichthyosis as a sign of predisposition to consumption."

Part II. provides records of cases and references to literature seeking to establish an association between consumption and squint. Part III. is an elaborate monograph on the connexion between consumption and non-tuberculous nasal abnormality. Here are collected records of a large number of cases with illustrations and a valuable bibliography in the form of footnotes. Although the author's thesis can scarcely be considered established, his material has been skilfully brought together and effectively presented. In Part IV., which is designated "Conclusions: An Examination of Lunatics—Protocol," the author elaborates his main conclusion: "Back to diathesis!" The volume closes with a tabular summary of 500 cases investigated by the author. The volume is a record of much painstaking research and merits consideration as a serious attempt to penetrate into the perplexities of some of those states and conditions which we collectively designate "predisposition." The numerous illustrations add much to the interest of the study.

Burns and Their Treatment. By J. M. H. MACLEOD, M.A., M.D. Aberd., F.R.C.P. Lond., Physician for Diseases of the Skin, Charing Cross Hospital, Royal Flying Corps Hospitals, &c. London: Henry Frowde and Hodder and Stoughton. 1918. Price 6*s.* net.

THE author of this excellent little book states that the manuscript was written originally in order to extend his own knowledge of the treatment of burns, of which severe and extensive examples came under his care in the hospitals of the R.F.C., and elsewhere. To a careful summary of the work of others in regard to burns and their treatment, there is added the author's own ripe experience, and the happy result is a practical text-book; every practitioner who reads it will keep it for reference. The serious disadvantages of the older methods of treating burns by occlusive and greasy applications are pointed out, and the more modern methods are described. The "open method," that of healing under a natural scab while continuously exposed to the air, is regarded as the simplest and in many ways the best for extensive burns, and it has the great advantage that it does not necessitate the terrible ordeal of periodical redressings. Methods of healing under an artificial scab, and especially the paraffin method, have been extensively employed during the present war, and it is gratifying to learn that grafting for large unhealed surfaces is largely avoided under the newer methods of treatment. Applications of X rays or radium have been found of value in reducing unsightly hypertrophic scars, but fibrolysin injections have proved disappointing. The book deals also with other forms of burns than those due to intense heat—namely, with electricity burns, burns from lightning, X ray and radium burns, burns from corrosives, and with sunburn. There is a useful and interesting chapter on dermatitis from high explosives. The value of the work is enhanced by illustrations of different types of burns and of apparatus for methods of treatment, by well-selected references, and by a full index.

The Panel Doctor: His Duties and Perplexities. By T. M. TIBBETTS, M.D., D.P.H. Second edition. London: John Bale, Sons and Danielsson. 1918. Pp. 75. 2*s.* 6*d.*

AS we remarked at the time of its first appearance, Dr. Tibbetts's sketch portrait of National Insurance in the working supplied a want which many must have felt, and the first edition of the book was therefore rapidly exhausted. The author has now brought its subject-matter up to date, while the legal points have been re-examined and corrected.

THE LANCET.

LONDON: SATURDAY, JULY 20, 1918.

The Future of the Medical Profession.

THERE appears to be no doubt in the public as well as in the professional mind that now is the appointed time for placing the medical profession on a more stable basis, both as a calling for its members and as a service whereby the health of the people is to be maintained by the best preventive and curative measures. By Parliament we are promised a Ministry of Health, which will, at any rate, centralise official activities as far as State medicine is concerned, and which, if it is to play a live part in the scientific developments of the future, must break down all such barriers as are unnecessary or artificial between State medicine and the domiciliary care of the people. In many directions groups of medical men are preparing collective opinions to guide the Government in respect of the enormously valuable departure which is contemplated, and simultaneously the lay papers, interpreting, we may be quite certain, the wishes of their readers, are devoting space and thought to the practical ways in which the medical profession can be organised for the public good. It is being allowed that, as medical men will, under every scheme for the promotion and preservation of national health, be the administrative officers, there is sense in allotting fair treatment to them. Thus it would seem that if the Government in their projected legislation give expression to this view everyone will be pleased.

We publish this week three papers dealing with the future of the medical profession, which cover much common ground, even while they are inspired by different ideals and lay stress in marked manner upon different social, professional, and medical problems which call for early solution. Sir BERTRAND DAWSON'S Cavendish Lecture, delivered in two instalments before the West London Medico-Chirurgical Society, will be seen by our full abstract to contain a comprehensive and idealistic scheme for rendering the medical profession of greater value to the State, while demanding of the State more substantial recognition for doctors in their education and their calling than is now granted. The main novelty in Sir BERTRAND DAWSON'S scheme is the suggestion for the endowment of buildings and structures for medical purposes by the State. For an adequate medical service, efficiently staffed, he insists that there should be in each locality adequate buildings and equipment for diagnosis and treatment, and it is, he holds, in the housing of health services generally that grants from the State are most needed. The allocation and distribution of such grants must obviously be controlled by a powerful central body, and Sir BERTRAND DAWSON is in agreement with most thoughtful reformers in believing that the new Ministry of Health will at the beginning be associated in its work with the Local Government Board, as well as with the National Insurance Commission. In no other way could its early activities be developed, and its later utilities depend upon the direction of its start. The picture of an organised medical profession, grouped around local hospitals and clinics, and being at the same time in close relation with the central hospitals placed in the larger centres of the population, is a fascinating one. No doubt in this way the intellectual life of the medical profession would be acutely developed, and as a result preventive medicine and early treatment would work wonderful transformations in the national rates of sickness and incapacity. But these happy things will only come to pass if the medical profession will acquire more influence than it now possesses in the conduct of public affairs.

Professor BENJAMIN MOORE and Mr. C. A. PARKER, as officers of the State Medical Service Association, re-state in full the case for a State Medical Service, pointing out that both lay and medical publics are realising the meaning of the formation of a Ministry of Health. All can see that changes in the relation of doctors to the public must follow on the erection of the new bureau, and that some form of organised medical service will result. The essay by Professor MOORE and Mr. PARKER should be read, because it summarises briefly but fairly the collective views of various bodies, and thus presents in a definite form the headings at least of the questions which require to be settled if the new Ministry of Health is to work from the beginning in close coöperation between preventive and curative medicine, and unhampered by the legitimate resentment of medical men. The advocates of a State Medical Service belong to the "extreme left party," to quote Dr. LAURISTON E. SHAW'S phrase in the opening sentences of his essay on the relations which should prevail between the medical profession and the public; this is the party which sees salvation in the proposal that every medical man to whom the State has granted medical registration shall become the servant of the State. Dr. LAURISTON SHAW does not follow this path, though he is equally opposed to those who think that the medical profession can still prosper, independent of Government control, but deprived also of all the facilities for development which State assistance connotes. Dr. LAURISTON SHAW enjoys the independence of individuality in expressing his thoughts, and in an interesting paper gives a classification of professional functions which will form a useful basis of thought at the present moment. And we cannot too often repeat how necessary it is that medical men should take heed of what may be in store for their calling when the Ministry of Health comes. It is perfectly true that many questions of organisation cannot be discussed until the Ministry has been formed, but it is equally true that the medical profession can play an important part in the new departure from the beginning if they can formulate some general views and expand them on public grounds. If we are at the outset hopelessly divided the Bill in its final stages may bring us sad things—even a humiliating and mischievous dependence.

Annotations.

"Ne quid nimis."

BRITISH AID TO FRENCH WOUNDED

France's Day was celebrated in England last week, and in order to give the public an adequate idea of the extent to which Britain has already come to the aid of French wounded and victims of the war, the British Committee of the French Red Cross issued on the day an excellent compilation from the pen of Mr. Laurence Binyon, entitled "For Dauntless France" (Hodder and Stoughton. Price 10*s*. 6*d*.). The book is not a record of Red Cross work alone, but includes the activities of the English canteens and of the various enterprises undertaken in relief of the devastated regions and the refugees. The British units have received financial support from the French Government as well as the coöperation of many subjects of Allied and neutral countries not included in the scope of the present book, and it should not be forgotten that there is also a French War Emergency Fund in this country which helps to maintain the military hospitals under the Service de Santé. Mr. Binyon opens with a section entitled "The Call and the Answer," in which he surveys the scene in Western Europe from an imagined aerial vantage-point, and describes the working of hospitals and relief agencies as a whole. The first part of the book also includes an account of a sample day's work at the office of the Comité Britannique, which now employs more than 2000 people, and of the early and very valuable work of the French Flag Nursing Corps in placing English nurses at the disposal of the authorities at the very outbreak of the war. These 40 pages should be read by everyone who wishes to understand how slight a barrier *la Manche* has been between English and French coöperation in the work of healing and restoration. The second part of the book is an orderly record of the work, illumined in the third part by the compiler's vivid impressions of it as an eye-witness. A complete alphabetical list of workers is given in Part IV. A frontispiece in colour by Edmund Dulac embodies the dauntlessness which is the keynote of the book, and five other illustrations help the reader who has not crossed the Channel to picture the scenes described. M. Paul Cambon in his preface says that "tout ce que l'auteur a vu et recueilli tend à resserrer entre les deux peuples non seulement la confiance et le respect, mais, mieux que cela, le lien émouvant de la véritable amitié."

ŒDEMA OF THE GLOTTIS IN RHEUMATIC FEVER.

IN the *Journal of the Canadian Medical Association* Dr. L. M. Lindsay has reported a case of rheumatic fever with a very rare complication—œdema of the glottis.

A girl, aged 11 years, was admitted into the Children's Memorial Hospital, Montreal. Three days previously she had been taken ill with what appeared to be an ordinary attack of rheumatic fever, and 4-grain doses of sodium salicylate were given every four hours. On admission she was rather thin and pale. The most striking feature was swelling of the left side of the face and neck which pitted on pressure, and prevented her from closing or opening the eye. Scattered over the body were ecchymoses varying in size from a 5-cent piece to the palm of the hand, deep red, mottled, and sharply circumscribed. The left shoulder and the right knee and elbow were painful, tender, and swollen. The heart was somewhat enlarged, and there was a rough systolic apical murmur, transmitted round the axilla to the back. The tonsils were rather large and the pharynx was congested. The urine was normal. Five grains of sodium salicylate were given every four hours. On the following day she suddenly began to gasp for breath, and in a few minutes her condition became desperate. She was unable to draw her breath and was becoming cyanosed. Tracheotomy was at once performed and gave immediate relief. The œdema gradually diminished, although subcutaneous hæmorrhages continued to appear in crops, chiefly on the legs and thighs. They were much smaller than the original ones. After a week she was greatly improved and the tracheotomy-tube was removed. The temperature, which had usually been over 101° F., was now below 100°. Recovery was slow but steady. Cardiac hypertrophy and mitral insufficiency remained.

The question may be raised whether the purpura and œdema were not due to an idiosyncrasy to sodium salicylate, as this drug is known to produce purpura. Against this view is the fact that when the girl attended as an out-patient with vague pains and slight fever she was given 20 grains daily of aceto-salicylic acid for one week without causing purpura.

THE TREATMENT OF FUNCTIONAL NERVOUS DISORDERS IN THE ARMY.

"H. H." writes:—

"Within the next few months a considerable number of members of the medical profession will be called up to serve with the R.A.M.C. Some will be men of experience attached to the consulting staffs of hospitals in London or the provinces, and many will be anxious, if possible, to do work that has some bearing on the less mechanical aspects of medicine.

Now the present war has revealed a vast field for useful work in the treatment of those functional neuroses usually classed together under the heading of 'Shell shock.' The War Office has initiated a system for dealing with such patients in special hospitals, under the care of officers specially selected for the purpose. Opportunities for instruction in this branch of medicine are given to those who, like the majority of the profession, are unfamiliar with the treatment of the neuroses."

As a certain number of medical men who are interested in, or have had previous experience in, this work may be required, they should send in their names to the War Office, as soon as they are called up, stating their wish to undergo a course of training in this branch of medicine. In this way the treatment of functional nervous disorders in the army should fall into the hands of those competent to give it, and to give it with the necessary sympathy and enthusiasm.

REGISTRATION OF NURSES.

A FORTNIGHT ago we commented on two meetings at which the State registration of the nurse was the central theme, and expressed our confidence in the ability of nurses to settle their own polity in regard to it. In a detailed letter which she has addressed to us Mrs. Bedford Fenwick, who occupied the chair at one of these meetings, while expressing her appreciation of some of our conclusions, desires us to state that the amendment to which we alluded was not accepted by herself as chairman, as it was proposed by a person who was not a member of the society, and was therefore not in order. We accept the statement, adding a regret that no orderly means could have been found for holding out an olive branch. Mrs. Fenwick reproaches us for our unfairness in not allowing her to reply at length. We should have been glad to do so if space had permitted, but as it does not we must refer our readers, who desire further to pursue the controversy, to the *British Journal of Nursing*, where Mrs. Fenwick informs us that she will publish her reply in full.

THE FUTURE OF THE MEDICAL PROFESSION.

(Being an abstract of the Cavendish Lecture delivered before the West London Medico-Chirurgical Society on July 4th at the West London Hospital and July 11th at the Royal Society of Medicine.)

BY MAJOR-GENERAL SIR BERTRAND DAWSON, G.C.V.O.,
PHYSICIAN TO THE LONDON HOSPITAL.

I.—AN EFFICIENT MEDICAL SERVICE.

THE lecturer attributed the changes which are now impending to a growing appreciation of the fact that much disease is preventable, a growing sense that health is of supreme interest alike to the State and the individual, and that the best means for preserving health and curing disease should be available for every citizen by right and not by favour. He pointed out that the growth of knowledge made measures for prevention and cure of disease more complex, so that they were no longer within the power of individual effort. If organised measures were to be put within the reach of all it followed that an efficient medical service could not be self-supporting. Its provision implied not only men, but equipment, and both must be distributed according to the needs of the community. He drew a parallel between provision for education and for health. Education was at one time patchy, unorganised, and dependent on voluntary effort. Since 1870, when Parliament stepped in, the State service had gradually overgrown the voluntary system, because it was recognised that education should be available for all; that the State was responsible for this matter, and that the cost was too great to be borne by fees or by voluntary effort alone. Health organisation had followed a similar development, though tardily, and at a distance; yet health was a more fundamental need than education. The lecturer thus reached the conclusion that the medical services must have some kind of State aid and central control, and that for their efficiency coördinated effort or team work in specially equipped institutions for diagnosis and treatment was needed. He contended, further, that curative and preventive medicine could no longer be separated in accordance with any sound principle, and should be brought together in thought, teaching, and organisation.

Insufficiency of Present Organisation.

These propositions were neither revolutionary nor new, and the direction of recent progress had conformed to them; what was needed was their wider recognition and systematic application. Taking as concrete instances the history of the diagnosis and treatment of phthisis and venereal disease, he showed how team work had gradually displaced individual effort; and the same was true of heart affections and gastro-intestinal maladies. But the need for such advantages had far outstripped the provision. For the masses the few voluntary hospitals were wholly inadequate; the middle classes of moderate means fared worse; and even the rich suffered because the investigations were not carried out in a clinic, where results could be placed side by side and a collective judgment given. A recent and striking example of organised team work was afforded by the orthopædic centres set up by the Army Medical Service under the inspiring leadership of Sir Robert Jones.

Looking to the future it was certain that investigations would become more and more technical and collective, and treatment would become increasingly specialised, with the result that the home would become less and less suitable for the sick. The insufficiency of the present organisation denied to the general practitioner the opportunities he should have for doing the best work. Hence he was apt to get disheartened and to deteriorate, as would a workman without the best tools or an adequate workshop. Team work and organised equipment should be available to provide him with the means to help himself, for the general practitioner was a central pillar of any scheme of reconstruction. In order to attract the best type of brain and character to the profession of medicine opportunities must be provided for doing good work; for observation, self-improvement, and research; for adequate repose and adequate remuneration.

The general practitioner—taking the wider outlook—should concern himself with the maintenance of health as well as the curing of disease. He must be brought into the position of a rightful leader and skilled adviser in all that appertained to the social life and welfare of his district. This implied that his education must give more heed to preventive medicine and social service.

For an adequate medical service, efficiently staffed, there must be in each locality adequate buildings and equipment for diagnosis and treatment and for the housing of health services. Here State aid and central control were needed.

Outlines of Scheme.

Sir Bertrand Dawson next sketched the lines along which such development should proceed, first discussing the provision of hospitals and clinics, and the organisation of the local machinery of health. In each community the health organisation and the intellectual life of the doctors should be brought into close relationship; this would lead incidentally to closer coöperation among the doctors and greater freedom for recreation and repose. The local hospitals and clinics should be grouped in relation to central hospitals in larger towns, which would provide consultants and specialists for the district. Round the central hospital should be gathered health services, both preventive and curative, more amply provided with equipment and personnel than those of the local hospitals; and the central hospitals might, in turn, be subordinate to a still larger provincial hospital.

Dealing broadly with administration the lecturer held that the buildings and equipment of hospital clinics and laboratories should be constructed and maintained by the health authority. Professional and technical questions must be determined solely by the doctors; administrative questions by a health board, which should be composed of lay and medical members, in no case chosen from an area smaller than a county or large borough. In larger questions of policy the health boards should be controlled by the Ministry of Health. Whatever the actual plan, the principle must be maintained that technical matters were decided by medical men, thus putting right one of the errors of the Insurance Act. The skilled must be no longer under the control of the unskilled. Whilst the clinics and institutions should be controlled by doctors, it was clear that the doctors should be subject to an expert court of appeal; there should be a system of medical administration and appeal right up to the central body advising the Minister. The relationship of this scheme to the administration of the Insurance Act was discussed in general terms. Insured persons would be on the panel of their chosen doctor as heretofore, but would have the right of all citizens to the advantages of the buildings and equipment of the medical services. The insurance authority should be represented on the local health board, but it should not directly control the local clinics and hospitals. For a high standard of professional work it was essential that doctors should treat their own cases in the local hospital, with access to specialists when necessary.

From all this it would follow that more of a doctor's earnings would be by salary and less by fees; in fact, it would be a part-time salaried service. A full-time salaried service for all doctors, with the abolition of private practice, would be gravely detrimental to the best interests of both patients and doctors. Medicine stereotyped under such a system would become a soulless machine. Under the service which he proposed the lecturer anticipated that the public health would be guarded, and the beginnings of disease detected and dealt with at a stage when treatment was likely to be effective. The means of collective investigation and institutional treatment would be at hand. Further, the trusted medical man of the patient's choice would be more efficient because of the opportunities for self-improvement given to him. With regard to remuneration, justice demanded reform; adequate payment and reasonable conditions should be afforded to medical men so that they might do good work and live a reasonable life without anxiety. On the other hand, the number of patients whom a doctor undertook charge of should be more strictly limited. So long as huge panels were allowed pecuniary reward went too much to the man with physical endurance and plausible tongue, and too little to the man with brains and conscience.

Ministry of Health.

Turning to the proposal for a Ministry of Health, the lecturer regarded the setting up of a central authority to guide, inspire, and control the activities of the medical service as the most pressing of all reconstructive needs. The

political difficulties in the way of creating an independent department were great; expediency therefore suggested administrative association of the new Ministry with the Local Government Board and the Insurance Commission; but if this plan merely aimed at convenience of organisation without implying a wider outlook for the new Ministry than that of the Board and Commission, then the suggestion must be opposed. The Ministry would need to draw to its councils representatives from all departments of medicine, and these councillors must have real power with direct access to the Minister. The profession for its part must realise the weight of its responsibility, close its ranks, work out a sound policy, and improve its organisation for expressing its views. Thus it would secure that proper influence in public affairs which it now lacked as a collective body.

II.—THE TEACHING HOSPITALS.

The lecturer said that the primary function of the teaching hospital was education and research rather than the serving of the clinical needs of the district in which it was situated. The local or central hospital belonged to its town or county, and should be under the new health authority; the teaching hospital belonged to the nation, and should be affiliated to a university or the Ministry of Education. Attached to the teaching hospitals would be various institutes where the domains of medicine and social service would meet, such as maternity care, infant welfare, school hygiene, trade and occupational diseases, tuberculosis, venereal diseases, &c., and be directed by distinguished specialists who would be on the staff of the hospitals. These institutes would give post-graduate training to doctors and instruction to nurses and social workers. No doctor would be eligible for a post at a health clinic without evidence of special study and knowledge.

The Staff.

Elections to the staff of a teaching hospital should not be exclusively in the hands either of the staff or the administration of that hospital. An academic council, carefully selected by the university, should also have powers of recommendation. The numbers of physicians and surgeons should not always conform to a fixed standard, nor should it be a necessity forthwith to fill a vacancy. The distribution of beds into a fixed number per member of the staff should cease, and when a physician or surgeon resigned the exact number of beds allotted to him should not of necessity descend to his successor. All members of the staff should have beds, beginning with a few; then if there grew up a man of promise and reputation his clinic would be developed and his beds increased; in this way a clinic would grow up round a man instead of a man being sought out to inherit a clinic. Each hospital should develop those departments which corresponded to the talents of its teaching staff. A junior member of the staff proved to possess one or more commanding talents should be given increasing opportunity and equipment, and there would grow up a great department and clinic round *the* man. There would not only be beds for medicine, surgery, and special subjects, but beds would be available for collective investigation; he would allocate roughly half the beds to provide each member of the staff with a fixed minimum and the remaining half to strengthen the clinics above referred to and for collective investigation. By such a plan power would go to the most efficient, and the intellectual life of the hospital would be led and inspired by a few men of outstanding abilities. He did not advocate the appointment of a professor of medicine and of surgery with complete control in his department; these had become subjects too big to be compassed by the brain of one man.

Terms of Service in Teaching Hospitals.

He was opposed to the universal application of a whole-time principle to teaching hospitals, for it would produce a narrow caste of academic men aloof from the problems and difficulties presented by disease in the world of action, and so unsuited for the training of general practitioners; further, it would be unwise to eliminate entirely the unconscious stimulus to effort which the earning of professional income affords. On the other hand, many a promising man had been spoilt by the combined effects of unpaid hospital routine and the early struggles for consulting practice. He thought a limited application of the principle was sound. For the first five years after his appointment every member of the staff should be a whole-time officer and forbidden private practice; he should live in or near the hospital and be paid an adequate salary. During this time he should apply himself to training, teaching, and research; he would discover his bent, and make manifest his worth. For the succeeding ten years he should give half his time to the service. Members of the staff whose gifts were entirely academic should have facilities provided by which they could remain whole-time workers at a salary. To avoid staleness and parochialism, members of the staff should be sent away periodically for three to six months on tours of study. The old-fashioned line of demarcation between the work of the physician and surgeon should cease. Half of their beds should be common to both of them, corresponding to the idea that a large number of diseases have both medical and surgical aspects.

Radiographers and laboratory workers should be brought into closer contact with the wards. Each member of the staff should have attached to him, besides his resident officer, two or more clinical assistants, men who had distinguished themselves as residents in some teaching hospital. They would be whole-time workers, devoting themselves to work in their chiefs' wards, to teaching and research, at least one-third of their time being free for study and research work of their own.

Salaries should be adequate but not lavish, according to the amount of time and energy each member of the staff gives to the hospital, and guided by the consideration that junior men require more help in proportion than senior men. It was obvious that some State aid would be necessary. This on a small scale was now in being, grants being paid by the Education Ministry, the Local Government Board, and the Medical Research Committee. No doubt the Health Ministry would subsidise health clinics. Such a policy of State subvention was elastic and compatible with the continuance of voluntary support combined with adequate central control. Teaching and research in England were still starved.

The scheme he outlined, whilst modifying methods, upheld the ideals of English medicine, the essential principle of which was that the student should be taught his profession in the wards by personal contact with the sick, learning to observe, inquire, and understand, being trained in knowledge and sympathy, and training his powers of intuition, without which he could never reach the best in clinical medicine.

Post-Graduate Teaching.

Post-graduate study should be encouraged, and doctors should be given "study leave" periodically, during which their salaries should be continued. He looked forward to a comprehensive scheme of post-graduate study, coördinated with similar schemes in allied countries, whereby we should widen our mental horizon and constantly extend our knowledge.

Early Diagnosis: The Beginnings of Disease.

The more early the diagnosis the more preventive and successful became the treatment. We needed the early diagnosis of the clinic, followed by the preventive treatment of the sanatorium and the spa, which were especially needed to combat the effect of "strain" which was produced by the increased speed of modern life. "Strain" might manifest itself in several forms. 1. It might affect the arteries, producing eventually aortic disease, arterio-sclerosis, and cerebral hæmorrhage. 2. It affected metabolism, producing gout or nephritis. 3. Or it might show itself in the plain muscular fibre of the body, producing atonic dyspepsia and constipation, and leading later to such conditions as intestinal stasis, visceroptosis, and colitis. For these repose and regimen were necessary.

Sanatoria and Spas.

On the outskirts of a big city there should be organised *sanatorium* treatment, with provision of a sanatorium, open-air bungalows, equipment for physical culture, baths and other forms of hydrotherapy, games and mental diversion, the whole organised and controlled by a highly trained medical staff. In such an institution patients would live for a time (say six weeks); each would eat his prescribed diet, pursue his exercises and games, take any baths or other treatment prescribed, and his mental surroundings would be restful yet cheerful. Such treatment would often be compatible with, and indeed aided by, the pursuit of his usual employment. He would be shown how to keep health and prevent disease, and such an organisation would afford

opportunities for research and study into the beginnings of diseased processes.

The spa was another application of the same idea but on a larger scale, where the patients rest from their ordinary avocations. Natural waters were a useful adjunct, but were quite subsidiary to the climate, position, and careful organisation of régime and environment, mental and physical. Many of the most successful spas in Europe were those whose waters had no special qualities. Amongst the features needed were the following: good natural position—the whole resort planned so as to present the various treatments efficiently though pleasingly and in an environment of beauty and repose; physical culture in its various forms, with ample accommodation for games which, though remedial, would be attractive; baths and all forms of hydrotherapy; electrical treatments; music and other entertainments which rest and divert, but do not excite, the mind; suitable dietaries so arranged as to be attractive and not irksome. Natural waters, though advantageous as an addition, were in no way a substitute for the foregoing necessities. The running of such a spa presupposed guidance and control by the doctors, acting in conjunction with a far-sighted municipality ready to spend adequate capital in laying out its resort on generous and comprehensive lines, and hotels designed and administered for those in search of health. Spas needed clinics, special hotels, and sanatoria, all working together for a common object. The need and opportunity were great, with many of the continental resorts henceforth closed to us. Resorts fulfilling the conditions laid down for city sanatoria had a great future of usefulness and should be brought within the reach of all classes. They would repay their cost many times over from the increased health and robustness of those visiting them and on account of their wide usefulness.

THE CASE FOR A STATE MEDICAL SERVICE RE-STATED

BY THE PRESIDENT AND HONORARY SECRETARY TO THE STATE MEDICAL SERVICE ASSOCIATION,

BENJAMIN MOORE, D.Sc., F.R.S.,
LATE PROFESSOR OF BIO-CHEMISTRY IN THE UNIVERSITY OF LIVERPOOL;
AND
CHARLES A. PARKER, F.R.C.S. EDIN.,
SURGEON TO THE THROAT HOSPITAL, GOLDEN-SQUARE, W.

THE suggested Ministry of Health has aroused considerable interest amongst the public in matters affecting the health of the nation, and it has vividly brought before the medical profession the great question as to how it can best serve the community as guardian of its health and physical well-being.

Both lay and medical men are realising that with the formation of a Ministry of Health changes in the relation of doctors to the public must quickly follow, and it is recognised that some form of organised medical service will be called for. Just as in the past there has been a hopeless multiplicity of Government departments concerned with matters of health, leading to waste of energy and money and a lack of efficiency, so has there been a similar want of organisation in local administration and in the various services rendered to the public by the medical profession.

All are agreed that organisation is called for centrally, locally, and amongst individual members of the profession, and at the present time much discussion is going on as to the particular lines such organisation should follow. Under the circumstances it is not surprising that suggestions for a State Medical Service should receive their share of attention, and it may be of some use to state the case for such a service once again and to see how far other opinion is leading towards that solution.

The Five Essentials.

In order to build up a system of preventive and curative medical treatment which will secure to *all* the maximum measure of health the following reforms are essential:—

1. A Ministry of Health with a president of Cabinet rank, assisted by an advisory medical board.
2. A Medical Research Service.
3. A widened and improved Public Health Service.
4. Close coöperation between the preventive and curative medical services.
5. A Public Clinical Service.

There is very little disagreement of a serious nature in the medical profession regarding the first three suggestions, and as regards the third it is now generally recognised that in the future there must be a much closer coöperation between the Public Health Service, which serves the community, and any clinical service which will serve the individual. The scope and aim of preventive medicine should embrace much of what is now differentiated as curative medicine, and clinical medicine should include much preventive work. The higher development of scientific medicine is to prevent disease in communities rather than to cure it in individuals, and therefore both the preventive and clinical services should work together for this end.

The necessity for a better organised clinical service is also now widely admitted on general principles, but there is considerable divergence of opinion as to the nature, extent, and functions of such a Public Clinical Service. Before stating the views of the State Medical Service Association it will be well to epitomise those of some other associations of medical men.

Views of the British Medical Association.[1]

The British Medical Association is in favour of a Ministry of Health the administrative functions of which should be carried out by members representing on an equal footing the preventive and clinical sides of medicine, and in each administrative area there should be whole-time administrative medical officers for both clinical and preventive purposes.

In each local area the medical staff should be of the following classes: (*a*) exclusively for administration and inspection; (*b*) resident medical officers to institutions and those in charge of special clinics; (*c*) pathologists; (*d*) those engaged in giving advice and treatment to individual persons otherwise than under (*b*). Class (*a*) should be whole-time salaried officers; (*b*) and (*c*) should be salaried officers, either whole-time or part-time; whilst (*d*) should not be salaried officers, but should be remunerated either for actual items of work done or for the number of persons for whom they accept responsibility.

There should be hospitals, clinics or treatment centres, and pathological laboratories within each area, with possibilities of consultations open to all who are entitled to the advantages of the public scheme. Voluntary hospitals would be necessary and should be encouraged. Visiting practitioners and consultants at both public and voluntary hospitals should be paid for their services in proportion to the number of patients coming under the public scheme for whom they accept responsibility.

Views of the Panel Medico-Political Union.[2]

The Panel Medico-Political Union is in favour of a Ministry of Health, but against any form of whole-time State medical service for general practitioners. It would support any improvement of the present State service in any direction which would conduce to the public welfare. It favours a large extension of hospitals and the formation of public clinics and treatment centres. It sees no reason why consultants, specialists, and pathologists should not be salaried officers, whole-time or part-time. It insists that the principle of free choice of doctors and free choice of patients is one of vital importance and must at all costs be retained. If it can be properly safeguarded, the union has no quarrel with a whole-time salaried State service confined to its proper sphere.

Views of the London Panel Committee.[3]

The London Panel Committee is in favour of a comprehensive scheme of coördinated provision of preventive and curative treatment of disease for all classes of the community. Under the local authorities there should be established two distinct departments of the medical services, the one dealing with the public health services, the other with individual health questions, both preventive and curative, with close coöperation between the two services. It desires to see the public health services improved.

With regard to the clinical service, it is opposed to any system of whole-time medical officers except administrators, resident medical officers, and practitioners specially devoting

themselves to limited sections of professional work. It considers that medical assistance in the home should be given by a part-time service of general practitioners remunerated by capitation grants and assisted by a part-time service of consultants and specialists.

Finally, as regards institutional treatment it would have municipal hospitals established with general practitioners on the staff, such hospitals to be linked up with the voluntary hospitals, thus leading to the easy transference of patients from the one hospital to the other.

Views of the Society of Medical Officers of Health.

The Society of Medical Officers of Health, being of opinion that many forms of treatment (as for tuberculosis and venereal diseases) are in reality preventive measures, claim that all such measures come under the heading of preventive medicine, and that they can be best dealt with by an extension of the powers of existing Public Health Departments.

Points of Agreement and Disagreement.

It is thus seen that all these bodies are in favour of some form of clinical service so coördinated as to bring within the reach of all such patients as would come under the public scheme the benefit of easy access to consultants and specialists and of institutional treatment. The importance of "free choice of doctor" is insisted upon, whilst a salaried service of general practitioners, either whole-time or part-time, is opposed. All schemes imply some limit to those entitled to the benefits of the service, presumably by means of an income limit.

Views of the State Medical Service Association.

The State Medical Service Association is in entire agreement with these bodies as to the necessity of a complete and well-organised clinical service, including general practitioners, consultants, specialists of all sorts, and pathologists.[4] It would go further and also include within the organisation of the service dentists, midwives, nurses, and dispensers. Differences of opinion, however, occur when it comes to part-time medical officers remunerated by capitation grants and to the question of excluding patients whose incomes are above a specified limit; for advocates of a State Medical Service are of opinion that no permanent system of medical service can be satisfactory that is not free and open to all and that is not officered by whole-time salaried practitioners. The reasons for these views may be briefly summarised.

A Free and Open Service.

The Public Clinical Service should be free and open to all:—

1. Because health is of national importance, and likewise disease is a national danger. The health of the individual is consequently of national concern.

2. Because health and not the purse is the factor determining the needs of the individual. Disease being no respecter of persons, science in dealing with its prevention and cure cannot afford to be so.

3. Because a service organised for the poor is bound to be unpopular and inefficient, even as the Poor-law service has been in the past.

4. Because modern methods of diagnosis and treatment are becoming so elaborate and costly that people of even considerable means are quite unable to afford them.

5. Because an enormous amount of disease remains undetected and untreated, as shown by medical inspection of school children and medical examination of recruits.

6. Because the service should be in a position to seek out disease in its beginnings and to watch over contacts in cases of infectious diseases, which is impossible under any system of private practice in which the doctor has to await the call of the patient, who may be far advanced in illness before he thinks fit to send for him.

A Whole-time Salaried Service.

The service should be a whole-time salaried service in order—

1. To secure the fullest possible coöperation and mutual help between all practitioners in any given area. This is impossible under a system of remuneration by fees or by capitation grants.

2. To secure a good distribution of practitioners according to the needs of a locality. A comparison has often been made between Bermondsey and Hampstead to show the present inequalities.

3. To secure some regulation of the hours of work and regular holidays. With general practitioners all working together in a given area it would be possible for each of them to have certain hours "off duty" every day and generally one day a week and a regular annual holiday.

4. To secure that every practitioner should have, say, three months' education leave every third year.

5. To secure that men of age and experience shall not waste their time on work that might equally well be done by junior assistants or even trained nurses under supervision, time which might be employed in the more highly skilled departments of medicine and surgery.

6. To secure that there shall be no divided interests between a doctor's public and private work.

7. To secure freedom to all practitioners to give unfettered support to matters of importance to the public health. With members of public health committees or influential offenders against public health interests as private patients this is at present difficult.

8. To set the practitioner free from the competitive struggle and so enable him the better to devote his time to the advancement of knowledge.

Incidentally a whole-time salaried service would have further advantages. Practitioners would be relieved of a great deal of vexatious clerical work, of book-keeping, of sending out bills, and of haggling with patients over fees. There would be no bad debts and no necessity for debt-collecting agents. Salaries would be secure and regularly paid and doctors who have served the community would be entitled to a pension on retirement.

Central and Local Administration.

The scheme suggested by the State Medical Service Association would be centrally controlled and kept up to a high standard of efficiency by the Ministry of Health. It would be administered locally by the county and county borough councils and by the councils of the larger boroughs and urban districts. Hospitals for the use of the service would be greatly increased in number, partly by taking over and re-modelling the Poor-law infirmaries, partly by utilising many of the present military hospitals after the war, and partly by new construction.

The voluntary hospitals should be given the option: (*a*) of being taken over entirely by the Ministry of Health or the local authorities; (*b*) of receiving grants from the public authorities provided they were maintained at a proper standard of efficiency; or (*c*) of remaining on an entirely voluntary basis.

The local administering bodies would be responsible for the cost of their medical services, assisted by substantial "grants-in-aid" from the Ministry of Health according to the completeness and efficiency of the service.

The Service and Free Choice of Doctors.

The work of the clinical service would centre round the hospitals or treatment centres in close touch with the hospitals, and general practitioners would share the clinical work and form an integral part of the staff of the hospitals, so giving opportunities for specialisation. They would work in groups, the number in a group depending on the size and character of the locality to which it was attached. There would be senior assistant and junior assistant practitioners in each group, and promotion would be determined partly by merit and partly by length of service.

Patients residing within the area would ordinarily have the free choice of any of the doctors belonging to the group. In the best interests of both patients and medical staff it would be necessary to devise means for preventing an uneven distribution of work, and also for dealing with objectionable and frivolous patients. This could be accomplished by having a Committee of Assignment of doctors and patients, which would allow, as far as possible, free choice of doctors by patients and of patients by doctors, and this would give as much freedom of choice as there is in private practice at the present time.

In addition to the various grades of practitioners just mentioned, there would be junior to them such posts as clinical assistants, resident medical officers, and medical and surgical registrars, and senior to them there would be

[4] The S.M.S.A. includes, of course, within these categories women as well as men, and considers that the former should stand on an equality with the latter in every respect.

many central and local administrative medical officers, to all of which posts practitioners should be eligible.

No Bureaucracy.

It will be of the utmost importance to make sure that the Public Clinical Service of the future shall not be organised and managed in any bureaucratic spirit, which might not only make the conditions of service intolerable, but might tend to stamp out individuality and initiative. There will be three interested parties—the tax-payers, the patients, and the doctors—all of whom must have a say in the administration of the service. The tax-payer must have a voice in the expenditure of public moneys, the patients must have a court of appeal if dissatisfied, and the doctors must be left to manage all purely medical matters and must be given the predominating voice in determining the conditions under which they will serve the community. The function of the central organisation must be to stimulate and suggest and see that an active progressive spirit is maintained, but freedom must be left to each local authority and medical group to expand and develop its plans.

The Transition Stage.

Whilst a service such as that indicated above is thought to be ultimately in the best interests of the public and of the medical profession, it is fully recognised that it would be impossible and unfair to existing interests to force it suddenly on to the profession by Act of Parliament. There must be a transition stage during which considerable latitude must be given to men and women now in practice.

It has already been suggested in many quarters that the medical benefits of the National Insurance Act should be extended to all dependents of those now insured and to all Poor-law patients. This may be the line eventually adopted, though it will be regrettable unless drastic amendments to the National Insurance Act be previously made. Later on, by gradually raising the income limit, the scope of the service could be widened more and more until at last no one would be excluded from the benefits of the service.

At first, therefore, it may be necessary and probably beneficial, in order to avoid one medical service for the rich and another for the poor, to have part-time medical officers of the Public Clinical Service. On the passing of any Act of Parliament establishing a public service all registered medical practitioners might be given an option, to be exercised within a reasonable time, of becoming either a part-time or a whole-time medical officer, but anyone qualifying and electing to join the service after the passing of the Act should be accepted only as a whole-time salaried officer. In this way there would gradually be built up a whole-time salaried medical service.

As regards the method of remuneration of those electing to serve as part-time medical officers, it may be either by salary or by a capitation grant, only in the latter case the number of panel patients allowed should be strictly limited, as the practitioner's time would be partly occupied in private work. Those electing to devote their whole time to public work should be paid by salary, which should be based upon their previous professional status, and they should be guaranteed a pension and some compensation for the capital value of the practices which they abandoned. The latter could take the form of a capital sum on retirement or an increased pension.

Even when the public medical service became free and open to all, there would probably always be a few patients who would prefer not to avail themselves of it, and similarly there may always be a few medical men who would prefer not to enter the service. There would be no objection to the latter competing for the former in private practice, provided always that they conform to all laws passed on behalf of public safety and national health.

Now is the Time.

In conclusion, it may be pointed out that there are several reasons why a Public Clinical Service should be considered at the present time.

In the first place, the war is depleting the ranks of the medical profession by death and disablement, and at the same time conscription is so denuding the medical schools that there must be a serious shortage of doctors in the near future which it will take many years to make good, and the evils of which can only be overcome by organisation and coöperation.

Alongside the shortage of doctors, the work which must be undertaken is likely to increase. There will, unfortunately, be a large number of soldiers permanently disabled for whom medical supervision will be necessary, and there will be many widows and orphans unable to pay doctors' fees, but whose health must be preserved for the sake of the rising generation. Again, it is not improbable that there may be outbreaks of bacterial disease introduced into this country by the home-coming Army.

Again, some 10,000 medical practitioners have left their peace-time work and joined the R.A.M.C., and, in spite of the good intentions of their colleagues who have remained at home, their practices, to all intents and purposes have passed into other hands. A practice can be left in charge of a colleague for six months or so without very serious damage, but not so for three or four years. When the men of temporary rank in the R.A.M.C. return they will have little heart to set to work to rebuild their lost practices, but they will probably be ready and willing to continue to serve the community by administering to the needs of the civil population under conditions of work not unlike those under which they have served the military forces.

Lastly, at the end of the war there will be a great number of well-equipped temporary hospitals, nursing staffs, and a large accumulation of motor ambulances, motor-cars, surgical instruments and appliances, and pathological and X ray outfits which could be utilised with great economy for the establishment and maintenance of a Public Clinical Service, and for special hospitals and sanatoria required by the preventive branch of the National Service.

Some form of Public Medical Service is bound to come in the near future, with whole-time salaried medical officers, if only because from the administrative point of view it will be so much less complicated and so much more economical than any form of part-time service. It is therefore urgently necessary that all practitioners should unite to ensure that when it does come it shall be a service that shall be honourable to the best traditions of the profession and of the greatest possible service to the community.

MEDICINE AND THE STATE.[1]

BY LAURISTON E. SHAW, M.D. LOND., F.R.C.P.LOND.,
PHYSICIAN AND LECTURER ON MEDICINE, GUY'S HOSPITAL.

THE proper relationship which should subsist between the State and the profession of medicine is a question in which a constantly increasing number of medical men as well as of the general public is beginning to take an active interest.

Present State of Opinion.

At the time of the introduction of the Insurance Act the medical profession, so far as it had given thought to the matter, was roughly divided into three parties holding diverse views upon this subject.

An extreme right party held that beyond securing the proper education of registered practitioners, and providing from amongst them a service of sanitarians to safeguard our system of drainage and to control epidemics of disease, the State should leave the medical profession a free hand to carry out its beneficent work in absolute independence of all Government control.

An extreme left party saw salvation in the proposal of the Fabians that the State should become the direct employer of every medical man to whom it granted registration, and should make itself responsible for seeing that its medical servants faithfully carried out its instructions in offering to, or forcing upon, each member of the community such medical ministrations as the State deemed necessary for the maintenance of his physical health.

Between these two sections was a larger central party who, recognising the impracticability, whatever they might think of the idealism of these extremists, held that the time had arrived for the State and medicine to enter into an honourable partnership in order to secure that the benefits of our rapidly advancing medical science should be made available for the population as a whole as well as for each individual, irrespective of wealth or social position.

[1] An address to the Southwark Panel Practitioners' Association, May 31st, 1918.

Four years of war have altered our views of the nature and urgency of many problems, as well as of the best ways of dealing with them. There still remains a small army of devoted individualists in medicine prepared to die in the last ditch before they will surrender the smallest outpost of professional liberty. On the other hand, our experience of the efficacy in war-time industry of substituting coöperation with, in place of control over, workers of all kinds is leading many medical men and others formerly devoted to the State service ideal to join hands with the central party in endeavouring to formulate conditions under which the profession and the State can jointly work as equal and friendly partners for the national welfare.

The schemes for the formation of a Ministry of Health put forward by various organisations, lay or medical, are tentative proposals for preparing the way for such a partnership, but I do not here criticise any of these schemes in detail, but discuss certain general principles of governmental and professional organisation which must be borne in mind if any permanently successful coöperation between medicine and State is to be forthcoming.

A National Medical Council.

Some of the most interesting proposals for industrial reconstruction recently suggested are contained in the Interim Report on Joint Standing Industrial Councils prepared by the subcommittee, of which Mr. J. H. Whitley, M.P., was chairman. (Cd. 8606. Price 1*d*.) Although these proposals are primarily intended for the promotion of cordial relations between, and efficient joint output by private employers of labour and their workpeople, they are clearly equally applicable where the State or a local authority is jointly engaged with professional men in rendering any sort of service to the community.

The majority of Government departments seem to have failed to recognise the applicability of the recommendations of the Whitley Committee to the large class of activities in which they themselves play the part of the employer. But already there are indications that these departments will have to give way under the stress of public opinion, and that joint councils of representatives of Government employees and of the officials of the Government departments concerned will be constituted on the lines of the Whitley Report.

In order to secure an effective partnership between medicine and the State the establishment of a Joint National Council based on these principles is probably one of the most important steps. Its existence at the present moment would be of great benefit to the country. To such a body would naturally be referred the many difficult problems which have for so long held up the establishment of a Ministry of Health.

Such a Council would be an entirely different body and would have quite different functions from the General Medical Council. It would be a joint medical and lay body, regard being paid, so far as the medical representation is concerned, to the "various sections of the industry and the various classes of labour employed"—to quote the words of the Whitley Report. It is now the duty of the medical profession to consider and decide how the due representation of all classes of the profession shall be secured upon such a National Medical Council and to persuade the Government to arrange for due representation of appropriate lay interests.

Functions of a National Medical Council.—Such a Council, "meeting at regular and frequent intervals," should be of great national advantage in securing the constant progress of medicine and the constant application of such progress to the common good. Not only would such a Council assist coöperation between the Government and the profession, but it would also help to solve the many difficult problems involved in the proper relationship between the various Government departments interested in health questions.

Let it not be thought that such a National Medical Council can undertake the duties of the General Medical Council, or the British Medical Association, or the Royal Society of Medicine, or the Panel Practitioners' Medical Union, or the Association of Panel Committees, or any other of the many purely professional bodies promoting or safeguarding professional interests, educational, economic, and scientific. It can no more undertake these duties than it can become a substitute for the Insurance Commission, the Local Government Board, or the Ministry of Health. Its duty is to form a connecting link between the profession and other bodies concerned, in order to look out for all possible channels of progress and to promote smooth working by ensuring thorough mutual discussion of economic and administrative problems as they arise, and even before they arise.

Constitution.—Having regard to the importance of such a National Council's work the profession must jealously guard its status and its representative character. Definitely brought into being to safeguard general national interests, it must not be regarded as an instrument of any particular Government department. It must not be a mere advisory committee to the Ministry of Health. The non-medical members must not consist solely of representatives of the Civil Service, nor of the political party or parties for the time being constituting the government.

Independent men of high standing in science, commerce, and philanthropy should have due representation on such a Council not as nominees appointed by the Crown, but by direct election by such bodies as the Royal Society, the British Association, or the British Hospitals Association.

So far as the medical representation is concerned the profession should stand firmly for the right to elect directly its own representatives. Basing its claim on the Whitley Report it should demand that different classes of the profession should have adequate representation, and above all that the general medical practitioner upon whom ultimately falls the chief burden of safeguarding the public health shall be entitled to send to the Council a due proportion of men experienced in this special class of work. Joint councils, similarly constituted, should also be established in local health areas throughout the country.

A Ministry of Health.

The war has given a great impetus to the demand which has for many years been made by the medical profession that a special department of the Government should be established to control and coördinate the activities of the State in connexion with health problems. The immense number of the population who have been found to be physically unfit to take their due part in fighting or in any other work of national importance has brought home to us our serious neglect in protecting our people against preventable health deterioration. We have learnt by practical experience that the health of the individual is a vital consideration in all human activity, as interesting to the nation as to the individual himself.

When we come to look into the matter we discover that practically every Government department has gradually set up for itself a separate organisation for dealing in some way or other with the ill-health which, unprevented or unchecked, becomes a serious bar to its effective work. At all conferences where health problems have recently been discussed attention has been drawn to the multiplicity of Government agencies which may at the same time be dealing with the prevention or cure of disease in the same community, in the same family, and often in the same individual. It is well that this condition should be brought home to our legislators, for the overlapping, waste of energy, and positive harm to health that may be induced by this confusion calls urgently for reform.

Relationship of a Ministry of Health to the Health Work of other Government Departments.—A first step in the direction of such reform is undoubtedly the establishment of a Government department whose primary and sole preoccupation shall be the maintenance of national health. To this end every assistance should be given by all members of the profession towards the promotion of a Ministry of Health. But it must not be imagined that such a Ministry can be made responsible for all Government activities in which health problems are of importance. We are beginning to recognise that no Government department can afford to disregard the effect of its work upon national health or the effect of national health upon its work, any more than it can disregard the interdependence of its work upon national and individual finance. We shall shortly be compelled to appreciate in matters of health that our new Ministry of Health will have to bear towards all other Government departments a relation similar to that which in matters of finance the Treasury at present bears to other departments of the State.

The Ministry of Health must not be handicapped by dealing with matters outside its proper province merely

because it may be urged that such matters are intimately bound up with questions of health. It must not deal with local government merely because local authorities have great health responsibilities. It might equally be urged that the Ministry of Health should manage the Army and the Navy, because no troops can carry on a successful campaign unless their health is properly safeguarded. The Ministry of Health must not be responsible for the general details of the housing problem, although the national health is vitally concerned with its proper solution. It might equally be urged that it should be made responsible for the work of the Board of Agriculture and Fisheries, because without proper and sufficient food no nation can be healthy.

The care with which Parliament has restricted the work of the Treasury to purely financial problems, though allowing it to intervene indirectly in the work of other departments sinning against the principles of sound finance, must be equally exercised in restriction of the scope of the work of the new Ministry.

The Primary Classification of Professional Functions.

Assuming the establishment of a Ministry of Health with properly defined functions and with properly arranged relations to other Government departments, its success will very largely depend on its effective use of the professional material at its disposal. It is quite certain it will have no superfluous material to use extravagantly if it sets out to provide the amount of medical service which public opinion demands shall be provided in order to maintain the high standard of national health to which all look forward. Economy of doctor-power, seriously depleted by the war, will demand a careful division of labour and a classification of professional functions.

Domiciliary and Institutional Treatment.—The present chaotic condition of professional organisation has led to erroneous views as to the primary classification of the work of medical practitioners, which if they be not set right at the outset will inevitably lead to extravagance and inefficiency. A common error is to assume an initial division into practitioners engaged in domiciliary, and practitioners engaged in institutional, treatment. Such a classification is particularly unfortunate. It has no value whatever, so far as professional experience and training are concerned. The same patient, with the same disease of exactly similar severity, may at one time require for his condition institutional, and at another time domiciliary, treatment. The most unimportant variation in his home conditions or in his momentary financial circumstances may determine the need for one or other form of treatment. It may fall to the duty of the same medical practitioner to treat the same patient at one time in his home, at another in the hospital.

It is highly desirable that all medical practitioners engaged in domiciliary treatment should also have opportunities of undertaking institutional work, so that a classification such as has been suggested would be directly detrimental to extension of desirable professional experience. It is probable that our social conditions after the war will greatly increase the amount of institutional treatment required for cases of slight severity owing to the difficulty of securing domestic service in the homes of the middle classes. From every point of view such a classification is unscientific, and therefore unsatisfactory.

Preventive and Curative Medicine.—Another equally erroneous classification of the profession is that into practitioners of preventive and practitioners of curative medicine. The idea that this is a natural division of our professional functions is even more widely held than the erroneous idea already referred to. At first hearing it sounds plausible, but if acted upon in carrying out any large scheme of professional reorganisation it would lead to disastrous results.

Nothing is more important for professional progress than that every medical practitioner, whatever the actual scope of his work, should have always in mind that prevention is better than cure, and that every curative measure he may employ should be considered from the point of view of its ultimate effect in the prevention of further recurrences of disease and the maintenance of the patient's future health.

The intellectual interest in the diagnosis of diseased conditions, the spiritual joy of rendering help to the suffering, and the natural pleasure of watching the immediate effects of one's therapeutic efforts have always led the profession to take a greater interest in the curative side of its work. The call of the sick to be made healthy has always been more insistent than the call of the healthy to be kept from becoming sick. Even amongst the angels there is more joy over one sinner that repenteth than over ninety and nine just persons who need no repentance.

The natural logic of events has always laid the profession open to the taunt that it was more interested in disease than in health. A reorganisation of the profession based on the idea that a large section of its personnel should be definitely ear-marked as set apart for curative work only would crystallise a condition which all who have given thought to the matter regard as wholly undesirable.

Basis of Classification.—The natural and scientific classification of professional functions that must form the basis of the professional reorganisation to be promoted by the Ministry of Health is a division of the profession into medical men undertaking the prevention and cure of disease by regulating the conduct and environment of the community as a whole, and those undertaking the same functions for the individual units of which the community is composed —medical officers of public health and medical officers of private health.

The whole outlook, training, and mode of attacking their special problem by these two great branches of professional workers are as different as their ultimate aims are identical. Each branch must constantly keep before itself the greater advantage of attaining their end by preventing conditions which if they cannot prevent they will ultimately be called upon to remove. But the medical officer of public health must work by official regulations, sanitary laws, and compulsory powers, whilst the officer of private health must always rely on individual influence, education in personal hygiene, and patient persuasion.

Whatever may be the extent to which the public will submit to sanitary laws instituted for the protection of the community as a whole, any attempts to secure by compulsion submission to laws of personal hygiene necessary in order to maintain individual health are foredoomed to failure. A Ministry of Health setting out to assist the profession in coördinating its work for the national advantage must recognise this initial classification of professional functions if it is to avoid confusion, overlapping, extravagance, and inefficiency.

Conditions of Service.—Having thus defined the scope of the work of these two great branches of the profession, it is necessary to recognise the resulting implication as to the conditions of service of the medical men composing them. The medical officer of public health whose duty it is to assist in securing a common obedience to national sanitary laws must be the direct servant of the State. On the other hand, the officer of private health must be as free as possible from State control and be placed in the closest relation of trust and confidence to the patient who voluntarily submits his health and life to his medical attendant's judgment and control.

The necessary means of securing these indispensable relations between the medical officer of private health and his patient need not be dealt with here. They are well known to medical practitioners. It is enough to indicate that by most practitioners it is now agreed that, failing the maintenance of completely independent private practice, which is no longer possible, the system set up under the Insurance Act, with certain modifications and improvements, would appear to be the most satisfactory way of meeting the necessities of the case.

The Subdivision of the Work of the Primary Branches of the Profession.

Having established a primary division of the profession into those responsible for public and those for private health, it remains to consider a rational subdivision of these primary groups.

Specialisation as a means to efficiency by subdivision of labour is an essential feature of all modern organisation. In recent years medicine has shown to an extraordinary degree this general tendency. It has also given very striking illustration of the fact that mere subdivision of labour without considered coördination will never secure the best results. The introduction of a Ministry of Health and the definite institution of a partnership between medicine and the State should afford a fitting opportunity for a careful consideration of the most effective use of professional specialisation.

So far as the *medical officers of public health* are concerned the problem is not a difficult one. The introduction of a National Service of such officers, or of local services dealing with areas of adequate size, will provide a staff sufficiently numerous to allow its individual members to take up work in the various departments of public health already recognised, and in those new departments which will inevitably be gradually instituted. Places upon such a staff will easily be found for experts specialising in epidemiology, bacteriology, chemistry, microscopy, dietetics, and all other sciences forming the basis of sanitary science generally. The principles governing the inter-relationship of such workers will not be difficult to define.

It is when we come to the *officers of private health* that difficulties will arise, difficulties which will be all the more acute because of the want of system in specialism as it exists in ordinary private practice to-day. Difficult as the task may be, it must be grappled with if the nation is to profit from State intervention in professional organisation. It is impossible to deal with the whole question here. Some general principles only can be touched upon, but they are of great importance. Is there a primary classification of the functions of the section of the medical profession dealing with individual members of the community analogous to the primary classification of the profession as a whole which has already been laid down? Undoubtedly there should be.

The classification clearly cannot be made on the mere question of seniority. This was the method once adopted and even now not entirely discarded by the Army, and it obviously does not work. To assign certain medical duties to a practitioner because he has attained to the rank of major and others to another because he is merely a captain is not a feasible principle of organisation.

Nor is it desirable to classify medical attendants as the doctors of the rich and doctors of the poor. This would be as disadvantageous to the rich as to the poor and as detrimental to the public as to the profession. Nor should we make a primary division of the duties of medical practitioners based on a classification into hospital doctors and non-hospital doctors. Everyone hopes that one of the effects of reorganisation will be to secure continued hospital experience for all medical practitioners.

The essential classification of medical attendants in order to secure efficient division of labour must be a primary division into *general practitioners and specialists*. But to be effective such division must be complete. It will not be altogether popular with either section of the profession, nor, perhaps, in the first instance, with the public. But in the national interest it must be secured. Without it confusion, overlapping, and inefficiency are inevitable.

The rôle and ambition of the general practitioner should be to know something of everything, the rôle and ambition of the specialist to know everything of something. Each must recognise the advantages and limitations of his position. The work of each is of vital necessity to the community. Neither must encroach upon the other's province. The general practitioner only must undertake independent practice. The specialist must frankly accept the position of the consultant to the general practitioner.

Need of coördination.—It is impossible under any scheme of professional organisation for which the State accepts joint responsibility with the profession to permit a continuance of the competition between these two classes of practitioners which exists at present. The State must endeavour to replace such competition by coöperation. Competition and coöperation cannot go hand-in-hand. The general practitioner cannot be expected to make free use of the specialist's services if by so doing he is helping a competitor to compete with him more successfully and ensuring the ultimate destruction of his own practice.

Fortunately for those whose duty it may be to introduce this system of division of labour and coördination of work into the profession of medicine, there already exists in a sister profession an example of the process in full working order. The relations between the barrister and the solicitor which exist in this and some other civilised countries afford a satisfactory precedent for the conditions which must ultimately prevail in medicine. For all practical purposes it may be said that no barrister undertakes independent work for a client. He acts always as a consultant for a solicitor.

A primary division of medical attendants which would establish two classes of practitioners bearing to each other the relations existing between barristers and solicitors would be a big step towards ensuring to the community the advantages that should accrue to them from specialisation in medicine, advantages which, under present conditions, are undoubtedly denied to the largest sections of the population.

If the State and medicine are to work successfully together for the common good each must be willing to concede something to the other. The State is learning that in complicated technical industries it must allow the workers a fair measure of liberty and independence if high ideals and progress are to be given opportunities of development. Industries are learning that they cannot effect the fullest national service without receiving some measure of State assistance necessarily involving a certain degree of State control. These general principles must be recognised by the Government and the profession if the highest aims of medicine are to be attained.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions and donations to the Fund have been received during the week ending July 15th:—

* Per Dr. Des Vœux. † Per Sir Thomas Barlow. ‡ Per Sir Rickman Godlee.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

SOUTH LONDON HOSPITAL FOR WOMEN.—The anniversary of the opening will be celebrated to-day (Saturday), July 20th, when the hospital will be open for inspection from 3 to 6 P.M., and a concert held at 3.30 P.M. Tickets (including tea), 1s. each, may be obtained from the secretary, South Side, Clapham Common, S.W.4. A street collection on the same day will take place in Clapham, Balham, Tooting, and Streatham.

Correspondence.

"Audi alteram partem."

THE CULTIVATION OF PFEIFFER'S BACILLUS.

To the Editor of THE LANCET.

SIR,—The paper by Captains Little, Garofalo, and Williams, in THE LANCET of July 13th, is interesting in that it records the recovery of a hitherto unrecognised cause of "influenza" in a series of cases of the present epidemic. But their conclusions that the epidemic is not caused by Pfeiffer's bacillus are at least open to question.

Hitherto it has never been suggested, as far as I am aware, that Pfeiffer's bacillus will grow on a medium devoid of blood, except in symbiotic relationship with other organisms, notably xerosis and staphylococcus, and perhaps after many subcultures. Serum alone is of no use, the bacillus must have blood or derivatives of blood. Captain Little and his fellow workers also rely on not recognising Pfeiffer's bacillus in direct smears, but in the case of such a minute organism as influenza bacillus the evidence derived from direct smears is apt to be fallacious. The fact that no leucocytosis was observed is taken as evidence that the infection was due to some organism other than Pfeiffer's bacillus, whereas it is generally held that the reverse is the case; indeed, in most text-books influenza is usually coupled with typhoid fever as a cause of leucopenia.

The authors lay emphasis on the fact that they have fulfilled two of Koch's postulates, but they have neglected the elementary precaution of demonstrating that the diplococcus referred to is not to be found in normal individuals under the same conditions as their "influenza" cases.

My experience of a smaller number of cases than those examined by Captains Little, Garofalo, and Williams is that I have recovered Pfeiffer's bacillus in every case, a result partly attributable perhaps to the use of an improved medium, an account of which I hope to publish in the immediate future.—I am, Sir, yours faithfully,

Wimpole-street, W., July 14th, 1918. JOHN MATTHEWS.

EPIDEMIC ENCEPHALITIS.

To the Editor of THE LANCET.

SIR,—May I be allowed the briefest comment on Dr. F. G. Crookshank's letter in THE LANCET of July 13th *à propos* of my paper on epidemic encephalitis? It is well known that occasionally epidemics of acute poliomyelitis occur at other times of the year than summer and autumn, that occasionally cases like those of the present epidemic of encephalitis are met with during poliomyelitis epidemics, that occasionally meningeal symptoms are prominent in epidemic encephalitis, and so on. What I did was to compare the average case of acute poliomyelitis with the average case of epidemic encephalitis and point out the distinctions, and these distinctions are not invalidated by citation of the exceptional cases in either group.

I am, Sir, yours faithfully,

Harley-street, W., July 15th, 1918. S. A. KINNIER WILSON.

QUICK DIAGNOSIS IN MENINGOCOCCUS INFECTION.

To the Editor of THE LANCET.

SIR,—The article, "A Quick Method of Diagnosing the Type of Meningococcus in Cases of Cerebro-spinal Fever," by Major A. S. Gordon Bell and Miss I. M. Harmer, in THE LANCET of July 13th, is strikingly important from the clinical as well as the laboratory point of view, enabling the physician to exhibit the homologous serum at least 48 hours earlier than has been the case with the ordinary method of "type agglutination."

There is one point, however, on which I do not feel clear, and in regard to which perhaps the writers will enlighten me. Is it not possible that the results obtained were due to antibodies contained in the curative serum which was administered intrathecally, and that these antibodies had found their way into the blood stream?

I am, Sir, yours faithfully,

A. E HODGSON, M D.,
Captain, R.A.M.C.

Bacteriological Laboratory, Military Hospital, ——, N. Wales, July 15th, 1918.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue:—

Died.

Capt. R. A. Sillar, Australian A.M.C.

Wounded.

Lieut. G. Hull, New Zealand A.M.C.
Capt. H. M. Drake, R.A.M.C.
Capt. F. H. Goss, R.A.M.C.
Lieut.-Col. A. H. Moseley, D.S.O., Australian A.M.C.
Lieut. W. S. Gross, R.A.M.C.
Major J. A. Pridham, M.C., R.A.M.C.

Missing, believed Drowned (through the Torpedoing of the Canadian Hospital Ship "Llandovery Castle").

Lieut.-Col. T. H. MacDonald, Canadian A.M.C.
Major G. M. Davis, Canadian A.M.C.
Capt. W. J. Enright, Canadian A.M.C.
Capt. A. V. Leonard, Canadian A.M.C.
Capt. G. L. Sills, Canadian A.M.C.

Missing.

Capt. W. A. Rees, R.A.M.C.

Previously reported Missing, now reported Prisoners in German Hands.

Lieut. J. Findlay, R.A.M.C, attached Worc. Regt.
Capt. J. M. McKenzie, M.C., R.A.M.C., attd. Northd. Fus.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualty among the sons of medical men is reported:—

Capt. N. C. Swift, D.S.O., M.C., East Lancashire Regiment, youngest son of Dr. H. Swift, of Adelaide, South Australia.

FOREIGN DECORATIONS.

Belgian.

Croix de Guerre.—Capt. F. D. Annesley, R.A.M.C., S.R.; Temp. Capt. A. Climie, R.A.M.C.; Temp. Capt. R. A. H. Fulton, R.A.M.C.; Lt.-Col. H. C. R. Hime, D.S.O., R.A.M.C.; Temp. Capt. G. D. Maclean, R.A.M.C.; Col. C. C. Manifold, C.B., C.M.G., I.M.S.; Capt. (acting Lt.-Col.) W. Tyrrell, D.S.O., R.A.M.C., S.R.; Col. A. E. Ross, C.M.G., Canadian A.M.C.; Maj. J. H. Wood, Canadian A.M.C.; Capt. C. C. Simson, M.C., Australian A.M.C.; Lt.-Col. J. H. Neil, New Zealand M.C.

MEDICAL PRACTITIONERS AND AN APPEAL AGAINST GRADING.

The position of the medical practitioner who is not satisfied with his grading by a National Service Medical Board is practically that of any other man liable to military service. He may make an application to the Appeal Tribunal for the district in which he lives for leave to be re-examined and graded by the Medical Assessors. The application is required to be made not later than five clear days after the date on which written notice of his grading by the National Service Medical Board is given or sent to him, unless the Appeal Tribunal, for good reason shown, allow an application to be made after that period.

Such examination is, however, quite different from re-examination by a National Service Medical Board. If a practitioner desires to be re-examined by a National Service Medical Board the Ministry of National Service is usually willing for this to be done upon application being made to that department.

AUXILIARY R.A.M.C. FUNDS.—The usual quarterly meeting of the committee was held at 11, Chandos-street, W., on July 12th, Major Ewan Maclean being in the chair. Amongst other members present was Major-General T. H. Goodwin, Director-General Medical Services. From the benevolent branch for the relief of children of officers of the Auxiliary R.A.M.C. who died as a result of the present war grants were made in three cases. The amount granted was £176. Grants from the relief branch for the relief of the widows and orphans of the rank and file of the Auxiliary R.A.M.C. were also made. Subscriptions and applications for relief from either branch should be made to the honorary secretary, Auxiliary R.A.M.C. Funds, 11, Chandos-street, Cavendish-square, W. 1.

THE LANCET, VOL. I., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of June 29th is in preparation. Owing to the increasing shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a *post-card* (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

Medical News.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:—

FINAL EXAMINATION FOR THE DEGREES OF M.B., CH.B.

William Peach Taylor.

Part I. only (including Forensic Medicine and Toxicology).—Frederick Viel Jacques.

DIPLOMA IN PUBLIC HEALTH.

Alan Gabriel Bodman.

SECOND EXAMINATION FOR DIPLOMA IN DENTAL SURGERY.

Edward James Tucker.

UNIVERSITY OF LIVERPOOL.—The following degrees were recently conferred upon the undermentioned:—

DOCTOR OF MEDICINE.

Mikhail Azer, Clement Alston Hughes, Isaac Jacob Lipkin, Thomas Glynn Morris, Jaffir Rumjahn, and Rattan Chaud Watts.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Victor Isadore Levy, Frank Atkinson Prosser, and George Seymour Swan.

At recent examinations for the Diploma in Public Health (D.P.H. Liverp.) the following candidates were successful:—

E. H. T. Cummings, G. H. Darlington, J. Drummond, I. J. Lipkin, H. E. Middlebrooke, K. J. Rustomjee, and R. C. Watts.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE, SCHOOL OF PHYSIC.—At examinations held recently the following candidates were successful:—

INTERMEDIATE MEDICAL EXAMINATION.

Part II., Applied Anatomy and Applied Physiology.—*Cecil Emrys McQuade, George Hall Davis, *John Henry Brenell Crosbie, Isaac Levy, and Mary Horan.

FINAL MEDICAL EXAMINATION.

Part I., Medical Jurisprudence and Hygiene, Materia Medica and Therapeutics, Pathology.—*James Sinclair Quin (high marks), Thomas Donald Gordon (high marks), Harris Cohen (high marks), William Theodore Micks (high marks), Henry Alfred Burridge (high marks), *Charles John de Vere Shortt, William James Alexander Russell, Eileen Hilda Dowse, Christopher John Lawrence Brock, William Burton Fox, Samuel John Laverty, Richard Esmonde Murphy, Jessie Gilbert, and Olive Baile.

Medical Jurisprudence and Hygiene, Materia Medica and Therapeutics.—James Alexander Acheson, Samuel Reginald Hill, *Gerald FitzMaurice Keatinge, and *Frederick William Robertson.

Part II., Medicine.—Arthur Leslie Gregg, Percy Crowe Parr, John William Scharff, Lindley Albertyn, Jason Grant Bird and *Stanley Cyril Mitchell (equal), Louis John Patrick Murphy, *William James McClintock, *David Shields Prentice, Eric Reginald Tivy, Charles Going Ambrose, Benjamin Damer Merrin, Kenneth McGregor Greer, and Eric James Lyndon and Margaret Wolfe (equal).

Surgery.—John William Scharff, Edward Francis Wilson, Robert Meade Daly Devereux and Ernest Edward Rollins (equal), *William James McClintock, Rita Henry, James Edward Jameson, *Victor Millington Synge, and Benjamin Damer Merrin.

Midwifery.—Mary Christina Sheppard, Lindley Albertyn, Ethel Marjorie Luce, *Frank McGregor Ferguson, Robert Meade Daly Devereux, and Eric Reginald Tivy.

DIPLOMA IN PUBLIC HEALTH.

Part I.—James Beckett and Edgar Ormond Bowie.

Part II.—Robert Arthur Keane.

* Formerly Surgeon-probationer in the Royal Naval Medical Service.

The following awards have been made:—Fitzpatrick Scholarship: Harry Lee Parker. Medical Scholarships: Anatomy and Institutes of Medicine, Eric Henry Cooke Allen; Botany, Zoology, Chemistry, and Physics, David Sheridan Spence. Dr. Henry Hutchinson Stewart Scholarships: Anatomy and Institutes of Medicine, Adrian Johannes Louw Snyman and Essie Stuart Smyth (special, for two years); Botany, Zoology, Chemistry, and Physics, Dorothy Alice Daly. John Mallet Purser Medal: George Hall Davis. Cunningham Medal: Edith Florence Willock.

UNIVERSITY OF ABERDEEN.—The following degrees were conferred at the recent Graduation ceremony:—

DOCTOR OF MEDICINE (M.D.).

Alexander William Hendry.

BACHELOR OF MEDICINE (M.B.) AND BACHELOR OF SURGERY (CH.B.).

Joseph Alexander, William Buchan, William Adams Coutts, *John Alexander Dawson, *Alexander Mathieson Dugan, †George Septimus Escoffery (first-class honours), Isabella Ferguson, Alexander Campbell Hill, Mabel Gordon Lawson, Robert Douglas Lockhart, Alexander McKenzie, James Wallace Mann, John Morrison, Alexander Cowie Paterson, John Alexander Ross, *Agnes Loudon Semple (second-class honours), James Charles Sleigh, Sophia Kent Grant Stuart, and Gwendolen Jean Elmslie Wilson.

DIPLOMA IN PUBLIC HEALTH (D.P.H.).

Henry Reah.

* Passed Fourth Professional Examination with distinction.

† Passed Fourth Professional Examination with much distinction.

The John Murray medal and scholarship were awarded to Dr. George Septimus Escoffery.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A quarterly meeting of the Council was held on July 11th, Sir George Makins, the President, being in the chair.—The President reported the result of the meeting for the election of four members of Council on July 4th, as already published in THE LANCET of July 13th. He further stated that Mr. Lynn Thomas, being fourth on the poll, became substitute member for Sir William Watson Cheyne until July, 1925.—Sir John Bland-Sutton, Mr. W. G. Spencer, Mr. Lynn Thomas, and Mr. Hey Groves were introduced, made declarations in the terms of the oath prescribed by the Charter of 1800, and took their seats in the Council.—Lieutenant-General Sir Arthur Thomas Sloggett, K.C.B., K.C.M.G., K.C.V.O., A.M.S., was introduced, and after signing the by-laws and making the required declaration, was admitted a Fellow of the College.—Sir Berkeley Moynihan, C.B., was congratulated by the Council on being made Knight Commander of the Most Distinguished Order of St. Michael and St. George.—Diplomas of Membership were granted to three successful candidates.—It was resolved to grant, jointly with the Royal College of Physicians of London, diplomas in public health to six successful candidates.—A letter was read from Mr. Edward A. Dunn thanking the Council for their resolution of condolence on the death of his brother, Mr. L. A. Dunn.—The President reported that in pursuance of a suggestion which had been made to him he had taken steps to transmit the following message of greeting to the French nation *à propos* of the celebration of "France's Day" on July 12th in London, and on July 14th in Paris:—

From the President and Council of the Royal College of Surgeons of England.

"Brothers in Arms, we greet you! Bound by ancient ties of blood and by the memories of many a gallant contest in the past, to-day we stand as one nation united in a sacred cause. We have before us a sacred presage from the past. As the united efforts of Pasteur and Lister have laid low the tyranny of disease, so shall France and Britain conquer a tyranny still more remorseless. Our future brightens and shall endow Gaul and Briton with a common birthright to remain a splendid heritage for all time."

The following professors and lecturers were appointed:—

Hunterian Professors:—Arthur Keith: Six lectures on Hunter's Chief Discoveries; Gordon Taylor: Abdominal Wounds of Warfare; A. J. Walton: The Surgery of the Spinal Cord in Peace and War; David Ligat: The Significance and Surgical Value of Certain Abdominal Reflexes; T. B. Layton: The Surgical Aspects of the Collection and Transport of Wounded; Alexander Fleming: The Power of Chemical Antiseptics and of the Natural Physiological Processes in Septic Wounds; E. G. Schlesinger: The Treatment of Compound Fractures and other Severe Injuries of the Upper Limb.

Arris and Gale lecturers:—E. M. Corner: The Nature of Scar Tissue and Painful Amputation Stumps; E. M. Cowell: The Initiation of Wound Shock and its Relation to Surgical Shock; J. C. Briscoe: The Mechanism of Post-Operative Collapse of the Lungs.

Arnott Demonstrator:—Arthur Keith: Six demonstrations on the Contents of the Museum.

Sir George Makins was re-elected President and Mr. Haslam and Sir John Bland-Sutton were elected Vice-Presidents.

EPSOM COLLEGE.—The Council of Epsom College announce that there will be a vacancy for an Entrance Salomons Scholarship of £50 at the beginning of the Michaelmas term. The conditions of holding the scholarship are that the candidate shall show an adequate standard of education for his age and that his financial position is such as to make it impossible or difficult to obtain an education at the College without the help of the scholarship. Applications should be sent to the secretary at the office of the College, 37, Soho-square, W. 1, by July 29th.

DONATIONS AND BEQUESTS.—The late Miss Grace Ross Cadell, L.R.C.P. & S. Edin., has left by will £150 a year for life to each of her four foster-children, with remainder as to the capital sum to their children, or, failing issue, the capital in respect of the two female children to be paid to the University of Edinburgh for the medical education of women there, and in the case of the boys to the Edinburgh Medical Department. She also left, among other bequests, £2000 to the Edinburgh Hospital for Women and Children; £1000 to the Queen's Nurses in Scotland; £300 to the Leith Branch of the Queen's Nurses; and £100 to Leith Hospital. The residue of the property to be equally divided between the University of Edinburgh to help in the medical education of women and the Edinburgh Hospital for Women and Children.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Asylums Officers' Superannuation Bill.

Mr. BRACE, the Under Secretary to the Home Office, on July 16th introduced a Bill to make further provision for the application of the Asylums Officers' Superannuation Act, 1909, to officers in certified institutions for defectives and to provide for the aggregation of service in asylums and in such institutions. It was read a first time.

Medical Treatment of School Children.

After the Education Bill had passed its report stage in the House of Commons on Tuesday, July 16th, it was formally recommitted in respect of Clause 2 (development of education in public elementary schools). An amendment was agreed to which provided that it should be the duty of a local education authority amongst other things "to make adequate and suitable arrangements under the provisions of paragraph (*b*) of subsection (1) of Section 13 of the Education (Administrative Provisions) Act, 1907, for attending to the health and physical condition of children educated in public elementary schools." By the rules of the House it was found impossible to make an alteration of this kind imposing a public charge during the report stage of the Bill, and this is the reason for the formal recommittal in order to carry out the pledge regarding the medical treatment of school children.

Midwives Bill.

The Midwives Bill has been read a third time in the House of Lords.

HOUSE OF LORDS.

WEDNESDAY, JULY 17TH.

A Ministry of Health.

Lord WILLOUGHBY DE BROKE called attention to the desirability of establishing a Ministry of Health without undue delay; and moved "That this House urges His Majesty's Government to introduce at an early date a Bill to constitute a Ministry of Health." He made a long speech urging the necessity of coördination of the health functions of the various Government departments, and pressed the establishment of a Ministry of Health as a matter of war emergency.

Viscount HALDANE seconded the motion.

Viscount PEEL, in his reply for the Government, pointed out that the separation of the functions of local government from health questions would present many difficulties. The problem was extremely complex. He admitted that he felt some difficulty in giving a precise reply upon the motion because the matters which it concerned were now under the very close consideration of a Government Committee. That Committee was sitting again on the following day (Thursday), and if it had come to a decision his task would have been very much easier. If he did not offer resistance to the motion it must be understood that the words "at an early date" would be given a very large and liberal interpretation.

The motion was agreed to.

HOUSE OF COMMONS.

WEDNESDAY, JULY 10TH.

Indian Medical Service.

Colonel YATE asked the Secretary for India whether he had considered the representation submitted by officers of the Indian Medical Service, and whether he could make any statement on the subject.—Mr. MONTAGU replied: Through the courtesy of my honourable and gallant friend I have seen the paper to which he refers, and I have also received numerous other representations regarding the position of officers of the Indian Medical Service. The other day I received a deputation from the British Medical Association on the same subject. I recognise the importance to the Government and the people of India of an efficient and contented medical service, and I have undertaken to give the questions which have been raised in this connexion careful and prompt consideration. I am in communication with the Government of India on the subject.

Medical Officers at Malta.

Mr. R. MCNEILL asked the Under Secretary for War how many Army doctors were quartered at Malta; what had been the average number of patients in hospital there during the last 12 months; whether any of the doctors in Malta had been there for more than 18 months without coming home on leave; and, if so, whether he would arrange that doctors who had been in Malta for such a period should now come home on leave and be then employed on duty at home or in France.—Mr. MACPHERSON answered: Medical officers stationed at Malta have the same privileges as regards leave as other officers serving abroad. It is not proposed to bring home officers who have served for 18 months at Malta, but applications for transfer will receive consideration.

Treatment of Discharged Men in the West Riding.

Colonel ASHLEY asked the Pensions Minister whether he was aware of the lack of institutional accommodation for discharged men needing treatment; that in the West Riding alone there were some 792 men who were unable to obtain treatment owing to lack of accommodation; and what steps he proposed to take to remedy this state of affairs.—Mr. HODGE answered: I am aware that there is still in some parts of the country a lack of accommodation for the treatment of discharged men, and various measures to meet the need are being taken. The reports from the local War Pensions Committee show the need in the West Riding to be particularly marked.

Treatment of Tuberculosis in London.

Mr. BOOTH asked the President of the Local Government Board whether he had received a copy of the resolution passed by the London Insurance Committee in June making certain stipulations as to the practicability of a comprehensive scheme for the treatment of tuberculosis in London; and whether he had summoned a conference of representatives of the committee to meet those of the County Council.—Mr. HAYES FISHER replied: The answer to both parts of the question is in the affirmative. The conference was held this morning.

THURSDAY, JULY 11TH.

Panel Practitioners and Medical Certificates.

Mr. ALBION RICHARDSON asked the representative of the National Insurance Commissioners whether he was prepared to make arrangements to enable a man summoned to appear before a medical board, who could not afford to pay a fee to his panel doctor for a certificate stating his medical history, to obtain such a certificate free of charge.—Colonel GIBBS (on behalf of Sir E. CORNWALL) replied: The furnishing of such a certificate as is referred to in the question would, of course, be entirely outside the scope of a medical practitioner's agreement for services under the National Insurance Acts, and he would therefore be under no obligation to furnish it. Moreover, it is a fundamental principle that any information as to the state of health of an insured person which may come into the possession of a doctor by whom he is attended under the provisions of the National Insurance Acts is strictly confidential, and is to be used for national health purposes only. In these circumstances it does not appear possible that such arrangements as the honourable Member suggests should be made under National Health Insurance, nor be paid for from National Health Insurance funds.

Mr. ALBION RICHARDSON: Will the honourable and gallant gentleman make representations to the Government as to the great injustice which this causes to poor men who cannot afford to pay for a medical certificate in being deprived of their only opportunity of laying their medical history before the medical board, and put in a much worse position than those who can afford to pay for a certificate?—Colonel GIBBS: Perhaps my honourable friend will put down a question to the Minister of National Service.

Mr. ALBION RICHARDSON: I will put it to the Prime Minister.

Medical Students.

Mr. HOLT asked the Minister of National Service how many male medical students under 28 years of age there were in the United Kingdom; and what steps were being taken to provide a supply of male doctors in the immediate future.—Sir AUCKLAND GEDDES said in reply: I regret that I cannot state how many male medical students under 28 years of age there are in the United Kingdom. There are, however, at present 5380 male medical students and 2250 female medical students at work in the schools and hospitals. The male students freshly registered in 1917 numbered 1378, as against 1366 in 1914.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: J. A. L. Cook, G. Blarton, G. B. Lowe.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel G. G. Delap relinquishes the temporary rank of Colonel on re-posting.

To be acting Lieut.-Colonels (while specially employed): Major R. V. Cowey, Temp. Major J. C. Davies (while in command of Medical Units), Capt. (acting Major) C. H. Denyer, Capt. J. Rowe, Temp. Capt. G. D. Hindley.

Relinquishing the acting rank of Major on re-posting: Lieut. (temp. Capt.) H. A. Rowell, Temp. Capts. T. Russell, H. F. Sheldon.

To be acting Majors: Capts. F. S. Tamplin, C. McQueen, M. O. Wilson, W. Mathieson, H. W. Carson, M. White, F. G. A. Smyth, W. L.

Webster, G. S. Parkinson, G. O. Chambers, R. Gale, E. C. Beddows, R. E. Todd, A. D. Stirling, A. L. Robertson, T. I. Dun, W. V. Corbett, S. M. Hattersley, J. C. A. Dowse, A. H. Heslop, T. H. Balfour, O. W. McSheehy, S. D. Large, F. G. Thatcher, F. R. Laing, E. B. Marsh, T. J. Kelly, N. Cantlie, J. H. Pendered, C. de W. Gibb; Temp. Capts. M. Bates, J. I. P. Wilson, W. J. J. Arnold, C. L. Spackman, W. H. D. Smith, N. I. Sinclair, W. H. Sheffield, J. W. C. Gunn, R. H. Strong, E. E. Chipp, G. Stiell, A. R. Muir, E. R. D. Maconochie, E. B. Smith, L. ap I. Davies, T. F. Saunders, R. Massie, P. W. Hampton (whilst specially employed), M. P. Paton, E. J. Selby, L. R. Broster, F. B. Winfield, L. Meakin, B. Whitehead, W. H. Alderton, L. Anderson, J. R. M. Whigham, D. E. Crosbie, A. H. Spicer, A. E. Knight, G. Rankine, A. P. Saint, A. S. K. Anderson, A. K. Cosgrove, R. M. Handfield-Jones, H. B. G. Russell, W. S. S. Berry, H. G. Kilner, J. Biggam. C. J. H. Sharp, R. S. Dickie; Lieuts. (temp. Capts.) W. T. Hare, M. B. King, D. Pottinger, A. E. Richmond, J. W. O'Brien, C. Russell, L. G. Bourdillon, H. A. Rowell, E. Catford.

D. Cairns, late temporary Captain, is granted the honorary rank of Captain.

Temp. Hon. Lieut. H. Halsted to be temporary Honorary Captain.

Lieut. H. C. Hinwood, Spec. Res., to be temporary Lieutenant.

Officers relinquishing their commissions: Temp. Capts. A. F. Mavety, B. N. Murphy, C. S. Glegg, W. R. Hodge; Temp. Hon. Capts. E. V. Jones (on ceasing to be employed with Welsh Hospital, Netley), S. McC. Boyd (on ceasing to be employed with British Red Cross Society in France); Temp. Lieuts. A. H. Collins, C. Murray, W. Smith; Temp. Hon. Lieut. H. D. Havard.

Canadian Army Medical Corps.

Temp. Major P. K. Menzies to be temporary Lieutenant-Colonel.

To be temporary Captains: W. J. Grant, K. M. B. Simon, D. E. S. Wishart.

SPECIAL RESERVE OF OFFICERS.

Major (temp. Lieut.-Col.) J. Mackinnon to be Lieutenant-Colonel.

Captains to be acting Lieutenant-Colonels whilst in command of a Medical Unit:—(Acting Major) C. N. Gover, W. H. L. McCarthy.

F. Jefferson relinquishes the acting rank of Major on re-posting.

Captains to be acting Majors: A. R. F. Clarke, A. B. Mitchell, J. H. Beverland, D. S. Martin, P. Walsh, J. A. Hill, J. M. Darling, M. W. Paterson, W. F. McLean, D. C. MacDonald, J. G. McCutcheon, J. Walker, A. J. Clark, J. Vallance, G. F. P. Gibbons, G. Dalziel, K. K. Drury, A. J. Gibson, A. Wilson, D. Dougal, E. A. Mills, H. G. Penny.

Capt. E. R. Chambers and Capt. B. Shires to be acting Majors whilst specially employed.

Capt. H. M. Clarke is seconded for service overseas.

TERRITORIAL FORCE.

Lieut.-Col. E. A. Wraith to be an Assistant Director of Medical Services, and to be temporary Colonel whilst so employed.

Capt. (temp. Major) H. F. W. Boeddicker relinquishes his temporary rank on alteration in posting.

Capt. B. Robertshaw, from T.F. Res., to be Captain.

Capt. J. E. W. MacFall relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Major.

Capt. W. C. Hodges to be acting Major whilst specially employed.

Capt. (acting Major) W. C. Hodges relinquishes his acting rank on ceasing to be specially employed.

Capt. (temp. Major) F. Philip to be Major.

Lieut. C. D. Mathias to be Captain.

Capt. (acting Major) H. J. Gorrie relinquishes his acting rank on ceasing to be specially employed.

Captains to be acting Majors whilst specially employed:—G. B. Eadie, H. Duguid, G. B. Gill, G. E. J. A. Robinson, S. S. B. Harrison, J. Dundas, S. J. C. Holden, F. E. Withers (and remain seconded), F. L. A. Greaves, B. M. Footner, R. Fullarton, W. H. Rowell, A. Ramsbottom, D. J. Scott, H. M. Calder, F. W. C. Brown, S. S. Greaves, A. G. Hebblethwaite, S. J. Clegg, W. H. Davison, J. Dale, J. M. Hamill, L. R. Tosswell, O. W. D. Steel, W. D. Frew.

Capt. (acting Major) H. J. A. Longmore, relinquishes his acting rank on ceasing to be specially employed, and remains seconded.

Capt. (acting Major) J. H. P. Fraser to be acting Lieutenant-Colonel whilst commanding a Field Ambulance, and remain seconded.

Surg.-Maj. H. Skelding, from Yeomanry, to be Major.

Major (Brevet Lieut.-Col.) F. E. A. Webb to be acting Lieutenant-Colonel whilst specially employed.

Capt. (acting Major) T. W. S. Paterson relinquishes his acting rank on ceasing to be specially employed.

Captains to be acting Majors whilst specially employed: J. G. Cooke, M. S. Doubble, A. W. Berry, A. P. Thomson, E. V. Connellan, A. Jones.

Capts. (acting Majors) A. W. Berry and A. Jones relinquish their acting rank on ceasing to be specially employed.

Capt. (acting Major) H. A. Macmillan to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. G. A. Auden is restored to the establishment on vacating the appointment as Deputy Assistant Director of Medical Services.

Lieutenants to be Captains; F. J. E. China, L. Hawkes, H. L. Robinson, T. M. Ormiston.

Capt. R. O. Sibley is seconded whilst holding an appointment as Deputy Assistant Director of Medical Services.

Capt. (acting Major) G. E. St. C. Stockwell to be Major.

Capt. A. W. Harrington is seconded for duty with a General Hospital.

Capt. (temp. Major) A. Don relinquishes his temporary rank on ceasing to be specially employed.

Capt. H. L. Gregory to be Major.

Capt. J. Saffley, from T.F. Res., to be Captain.

TERRITORIAL FORCE RESERVE.

Lieut.-Col. W. A. Benson, D.S.O., from R.A.M.C., to be Lieutenant-Colonel.

Major C. W. Edwards, from R.A.M.C., to be Major.

Capt. H. J. Wheeler, from R.A.M.C., to be Captain.

Capt. W. E. Falconar, from R.A.M.C., to be Captain.

ROYAL AIR FORCE: *Medical Branch.*

Lieut. N. F. Stallard to be Captain.

Granted temporary commissions:—As Major: A. Paling. As Captains: J. B. Guthrie, C. S. Dowdell. As Lieutenants: E. L. Bunting, A. Read.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The first article in the June number of this journal is a report from the Hygienic Department of the Royal Army Medical College by Major A. G. R. Foulerton on the Pathology and Treatment of Poisoning by Trinitrotoluene (T.N.T.) and on the Action of Certain other Poisons which Affect Metabolism. His measures for the protection of the worker from undue exposure to the action of the poison include the avoidance of fatty foods and their replacement in the dietary as far as practicable by sugars; and the elimination of any trinitrotoluene already fixed in the fatty constituents of the skin by frequent baths, followed by brisk friction of the skin.—In Malaria in Macedonia, with Especial Reference to the Use of Prophylactic Quinine, Captain C. H. Treadgold concludes that small doses of prophylactic quinine, not too long continued, are of proved utility to the natives of malarial countries, both in the absence of anti-mosquito measures, and when such measures are incomplete, and that quinine may be given with advantage to immigrants under certain conditions, but, speaking generally, he holds that quinine prophylaxis in the absence of protection against mosquito bites is little more than a pious fraud perpetuated from one generation to the next, because public opinion has not been sufficiently enlightened to encourage the working out of the problem on scientific lines.—Captain F. B. Chavasse discusses "Myalgia" (a term originally introduced in order to rescue a certain class of case from the heading "rheumatism"), its Diagnosis in Forward Areas; Captain W. Waddell deals with Post-Dysenteric Diarrhœa; and Lieutenant-Colonel Gordon Holmes continues his paper on the Symptoms of Acute Cerebellar Injuries as Observed in Warfare.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-urinary Diseases, S.W.—H.S.

Birmingham, Erdington Infirmary and House, and Selly Oak Infirmary and House.—Locums. £7 7*s.* per week.

Birmingham University.—Sen. Demonstrator of Anatomy. £250.

Bristol Royal Infirmary.—H.P. and H.S. £120.

Bromley Education Committee.—Temp. School M.O.

Bury and District Joint Hospital Board.—Asst. Med. Supt. £450.

Bury Infirmary.—Jun. H.S. £200.

Dudley, Guest Hospital.—Asst. H.S. £120.

Great Northern Central Hospital, London, N.—H.S. £100.

Hospital for Consumption and Diseases of the Chest, Brompton.—Asst. Res. M.O. £100.

Hospital for Sick Children, W.C.—H.S. £100.

Kensington and Fulham General Hospital, S.W.—Res. M.O. £250.

Leeds, Neurasthenic Hospital for Pensioners, Allerton Hall.—M.O. £400.

Liverpool, Township of Toxteth Park, Poor-law Institution and Infirmary.—Asst. Res. M.O. £300.

Manchester County Asylum, Prestwich.—L.T. £7 7*s.* per week.

Metropolitan Hospital, Kingsland-road, E.—L.T. £5 5*s.* per week.

Pinewood Sanatorium, Wokingham, Berks.—Asst. M.O.

Queen's Hospital for Children, Hackney-road, E.—M.O. for Elect. Dept.

Reading, Royal Berkshire Hospital.—H.S. £250.

Royal Air Force.—Female M.O. 24*s.* a day.

St. Albans, Herts County Asylum.—Temp. Asst. M.O. 7 guineas a week.

Scottish Women's Hospitals (N.U.W.S.S.).—Female Chief M.O. for Camp Hospital in Macedonia. £400.

Sheffield City Education Committee.—Asst. School M.O. £400.

Sheffield Royal Hospital.—H.P. £140. Also Cas. O. £135.

Sheffield Royal Infirmary.—H.S. £120. Also H.P. £120.

South London Hospital for Women, S.W.—Female Temp. Asst. P.

Stoke-on-Trent County Borough.—Asst. Tuberc. O. £360.

Walsall Education Committee.—L.T. Sch. Med. Insp. £400.

Wilts County Council.—Oculist and Asst. School M.O. £400.

York County Hospital.—Female H.S. £200.

Births, Marriages, and Deaths.

MARRIAGES.

STEVENS—EARLE.—On July 10th, at St. Peter's, Belsize Park, London, N.W., John Barr Stevens, M.D., Major, R.A.M.C.(T.F.), to Mabel, only daughter of the late Major-General W. H. S. Earle, Bengal Staff Corps.

VICKERY—JOHNSON.—On June 27th, 1918, at Lisburn Cathedral, by the Reverend Canon Carmody, Captain Edward Percival Hadden Vickery, R.A.M.C., youngest son of Dr. and Mrs. Vickery, Kinsale, to Gladys Ruth, third daughter of the late Mordecai Johnson, of Greystones.

DEATHS.

CONSTABLE.—On July 6th, in a nursing home in London, Samuel Constable, L.S.A. Eng., son of the late Rev. J. Nicolson Constable, B.A.T.C.D., Rector of Swinford, Co. Mayo, aged 62 years, of West Green, N., and Ballyglasheen House, Clonmel, Co. Tipperary, deeply lamented by his wife and family.

GAUNTLETT.—On July 3rd, at Cilfynydd, Pontypridd, Owen Binns Gauntlett, M.R.C.S., L.R.C.P., aged 40.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

AMERICAN MEDICAL ASSOCIATION.—Sir James Mackenzie, Sir W. Arbuthnot Lane, and Colonel Herbert A. Bruce attended the recent annual meeting of the Association at Chicago as representatives of the British Government. Addresses on the part played by the medical profession in the war were given to large audiences at Cincinnati, Chicago, Toronto, Boston, and other cities. Sir Arbuthnot Lane delivered an address, reported in full in the *Chicago Evening American* of June 13th, on the treatment of facial injuries, describing the work of the Queen's Hospital at Sidcup.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
Clinics each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.
(Details of Post-Graduate Course were given in issue of June 29th.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Out-patients each day at 2.30 P.M.

THE THROAT HOSPITAL, Golden-square, W.
MONDAY, July 22nd.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

BRITISH ORTHOPÆDIC ASSOCIATION, at the rooms of the Medical Society of London, 11, Chandos-street, W.
FRIDAY, July 26th.—10 A.M., President's Address:—Mr. E. M. Little. 10.30 A.M., Discussion on the Indications, Technique, and End Results of Tendon Transplantation in Gunshot Injuries of Nerves (opened by Capt. T. P. McMurray). 2.15 P.M., Mr. J. J. Clarke: Demonstration of Special Instruments for the Open Operation for Congenital Dislocation of the Hip. Major S. A. Smith: The Preparatory Treatment of Amputation Stumps. Other Short Communications by members of the Association.
SATURDAY.—Discussion on the Abbott Treatment of Scoliosis (opened by Mr. D. M. Aitken).

ROYAL SANITARY INSTITUTE, in the Council Chamber, Town Hall, Ipswich.
SATURDAY, July 27th.—11 A.M., Discussions:—Housing, from the Point of View of Economy in Planning and Construction (opened by Sir Henry Tanner), and on the Provision of Maternity Homes (opened by Dr. A. M. N. Pringle). 2 P.M., Visits to the Public Health Office, Sanatorium, Fever Hospital, Electricity Station and Destructor, Small-pox Hospital, and New Water Works.

EDITORIAL NOTICES.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.
Offices: 423, STRAND, LONDON, W.C. 2.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. G. R. Anderson, Southport; American Red Cross Institute for Crippled and Disabled Men, New York, Director of; Mr. R. B. Atkinson, Cambridge.

Notes, Short Comments, and Answers to Correspondents.

TRIPLEX GLASS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 12th you published a letter on triplex glass written by me, and I can now supplement the account then given with illustrations which speak for themselves.

Fig. 1 shows the result of a trial which I myself made by shooting from a distance of 30 yards at glasses fixed on a board. The glass is starred and its surface broken into small pieces, but there are no splinters and no shot went through. The illustration shows the glasses made up into spectacles.

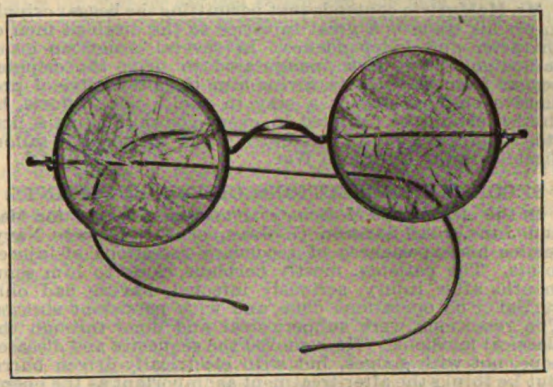

Fig. 2 shows the wind-screen of a motor-car struck by nine shrapnel bullets from a shell which burst quite near. Only one bullet perforated the glass, and this did not travel beyond the hole which it made.

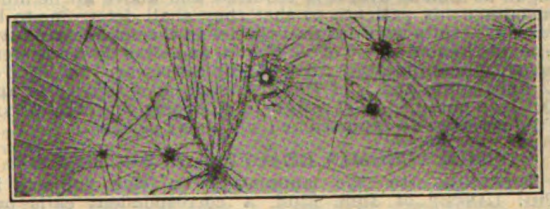

Triplex glass is now being widely used for eye protectors for our fighting men, but as yet its use for glasses designed to correct anomalies of refraction has not become general; indeed, it is almost confined to private practice. I am in the habit of advising everyone who has to wear glasses for going about to have them made of triplex glass. The lenses are said to be more difficult to grind and the expense is greater, but the immunity from injury is quite worth the extra outlay. Opticians tell me that the difficulty in grinding is slight, except in the case of deep curves, and, as I pointed out in my previous communication, this can easily be overcome by fixing a flat plate of triplex in front of the lens of ordinary glass remedying the anomaly of refraction. There is more difficulty when it is required to grind lenses on the glass of protectors. This takes an enormous amount of time, and can only be done by a highly skilled workman. But it is unnecessary. There is no difficulty whatever in wearing protectors over the glasses used for visual purposes, in the same way as a lady who wears glasses pulls her veil down over them.

Difference of opinion exists as to the best colour for protective spectacles in Eastern countries. I have tried blue, neutral, chlorophyll, and Stokes's, without finding any difference whatever in the acuity of vision, even when the darkest shades were used. I have experimented on myself and found no difference in looking at test types or distant objects. I could see just as well through coloured glasses as without, but darkest chlorophyll shade was the most comfortable to the eyes. Some attempt is being made to determine which is the most suitable dye to use. Would it not be better to find out which dye can be procured at once and in sufficient quantity, and to use it?

I am, Sir, yours faithfully,
CHARLES HIGGENS, F.R.C.S.

Brook-street, W., July 13th, 1918.

CRIPPLES AND BEGGARS.

THE American Red Cross Institute for Crippled and Disabled Men calls attention to the prevalent confusion in the public mind between the idea of a cripple and that of a beggar, with resulting injury to the cause of the self-respecting disabled man who is regarded as a subject for charity rather than for trade training and employment. A recent report of the London Mendicity Society states that many thousands of pounds are squandered every year on street beggars in London alone, and crippled beggars seem also to be in evidence in New York streets, for Mr. Douglas C. McMurtrie, director of the Institute, writes:—

We have seen many cripples at street corners, making public exhibition of their deformity or amputation and soliciting alms of the passers-by. The number of these beggars is small in comparison to the great body of physically handicapped men who are usefully employed, but the few have vigorously advertised, have made a considerable impression on the susceptibilities of the community, and have reaped a profitable harvest. A bank teller reported recently the case of a crippled street beggar who deposited in a savings' account, after paying his living expenses, 40 dollars weekly.

Mr. McMurtrie contends that permitting the beggar cripple to ply his trade is a great injustice to the disabled men of character and independence. In several American cities campaigns have been inaugurated to drive the crippled beggar from the streets, giving him the alternative of productive employment or a stay in gaol. Such efforts, he thinks, should be imitated in every community as a first step in preparation for the return of the soldiers and sailors disabled in the European War.

SECONDARY RESECTIONS OF INJURED JOINTS.

IN the *Archives de Médecine et Pharmacie Navales* for May and June, Staff-Surgeon G. Jean, of the French Navy, relates his experiences of secondary resections of injured joints. The patients, mostly Serbians, came to him some months after injury, seriously infected, having had only partial or no operations done, and with persistent sinuses. The resections were subperiosteal and done through the classical incisions. He removed the sequestra and diseased bone, not with gouges, but with electrically driven burrs. But he thinks the after-treatment as important as the operations. The surgeon must do the dressings himself, must himself adjust and watch the plaster splint, taking care it is not too soon removed from a leg or too long left on an arm. Especially must he see that passive movement is begun as soon as ever it is required, and above all he must encourage his patients so that they shall determine to be cured. Results were naturally better in the upper extremity. Nine of 11 shoulders, 9 of 11 elbows, and all of 3 wrists were saved from amputation: 8 of the hip cases were lost, but 5 of 12 knee-joints and 5 of 7 ankles made good recoveries, and Dr. Jean obtained good results in 16 operations on the foot. The cases are all reported and will repay perusal.

THE ALBUMIN REACTION IN SPUTUM.

REFERRING to the annotation on this subject in THE LANCET of June 22nd, a correspondent calls our attention to the fact that since the French Navy does not issue microscopes to ships albumin reaction is used as their *discrimen*. The test is a good one for this purpose. It does not distinguish pneumonia from tubercle, but it does differentiate either from mere bronchitis.

A THERMOMETER FOR THE BLIND.

UP to the present time no thermometer has been invented that can be read by the tactile sense. The matter is of practical importance, as many blind men have entered on occupations in which it is necessary to know the exact temperature record. The Association Valentin Haüy pour le Bien des Aveugles (9, rue Duroc, Paris) is therefore offering a prize of 1000 francs for the best apparatus enabling the blind to read temperatures.

RATS AND PLAGUE.

AT a recent conference, held at Ipswich, of representatives of the sanitary, military, and naval authorities in East Suffolk Dr. G. I. T. Stewart, county medical officer of health, stated that although the regular examination of rats had been discontinued owing to the circumstances of the war, an outbreak of plague had been anticipated by the sanitary authority and the Local Government Board. On behalf of the Board Colonel Edmund Wilkinson pointed out the need for systematic destruction and examination of rats throughout the county. An Order had been issued by the Board to this end, and all except two of the local authorities in the county were carrying out the Order. For the Sampford district it was pointed out that 108,000 rats had been destroyed in a single year, and for the Woodbridge rural district 16,000 since last Christmas. The conference concluded by passing a resolution in favour of a vigorous and concerted campaign for the destruction of rats and the closest possible coöperation for this purpose between the civil, naval, and military authorities.

DELPHINIUM POISONING.

"Delphinium poisoning" was returned as the cause of death by a coroner's jury at Brentwood in the case of an inmate of the Essex County Asylum who died after eating part of a delphinium plant in the asylum airing court. It was stated at the inquest that owing to a fatality last year hollyhocks had been removed from the grounds, but it was not considered that delphiniums were dangerous.

This plant, with its tall spikes of generally pale blue flowers, is a common garden flower. Delphinium, or larkspur, as it is called, produces seeds which yield delphinine for destroying lice. The name of delphinium is derived from a fanciful resemblance of part of the flower to a dolphin, and the name of larkspur from the spur-shaped formation of calyx and petals. In popular parlance the name larkspur is confined to the smaller varieties. Delphinium is included by the Germans in their "Giftpflanzen" or poisonous plants under the name of "Scharfer Rittersporn," besides being called "louse-seed." In THE LANCET of Oct. 29th, 1887, a note on delphinine appeared, of which the following is an excerpt:—

The plant yields four alkaloids, of which the chief one, delphinine, occurs as an amorphous powder of yellowish colour and resinous aspect, and having the chemical formula $C_{29}H_{35}NO_6$. The parts of the plant usually employed therapeutically are the seeds, which contain the great part of the active principles. The seeds have for a long time been employed against psoriasis and as a vermifuge. Delphinine acts chiefly on the nervous system, and first upon the bulb, next upon the sympathetic. It produces at first a functional excitation, then, by graduated attenuation, a diminution and complete but transient abolition of sensation. It is said to be preferable to aconitine, because it is so much less toxic. On the motor nerves delphinine has no action in physiological doses, but in toxic quantity their functions are entirely abolished, causing incoördination with ataxia. The alkaloid acts also on the heart, accelerating the cardiac movements, until finally arrest occurs in diastole.

IMPROVED NOVARSENOBENZOL PREPARATIONS AND APPARATUS.

WE have received from Messrs. Modern Pharmacals, of 48, Mortimer-street, London, W.1, specimens of (1) an outfit for the concentrated intravenous injection of novarsenobenzol (914), and (2) an apparatus for the intramuscular injection of glucarsenol, a solution of novarsenobenzol in glucose with stovaine and guaiacol. The former outfit consists of a special vial of novarsenobenzol, an ampoule of distilled water sterilised and deprived of air and a suction filter. The technique is simple and conveniently carried out in a few minutes in the apparatus provided. The injection is prepared by pouring the contents of the ampoule of water into the vial containing the novarsenobenzol. The solution is drawn into the syringe by means of a small glass tube containing a filter of sterile gauze which fits on the syringe. This outfit is known as the "coneosan" outfit.

The glucarsenol is supplied in an ampoule syringe ("ampsyring") containing a sterilised solution. Glucose, it is stated, furnishes a liquid of thicker consistency than the aqueous solution, and, though slowly, is surely absorbed. It is said to produce no pain, and the slowness of absorption diminishes the pain due to the arsenical drug, the analgesics, guaiacol and stovaine, assisting. In addition, glucose is a reducing agent, and thus to some extent protects against oxidation.

FRANCO-AMERICAN SURGICAL APPLIANCES.

WE have received a brochure of 90 pages dealing with the apparatus manufactured by the *Comité Franco-Américain contre les Impotences Fonctionnelles* (at 17 Rue Boissonade, Paris) and supplied gratuitously to the sanitary formations of the French Army. President of the managing committee is the hospital surgeon, M. Paul Reynier, who states in a prefatory note that 18 months after outbreak of war, almost all the Paris orthopædists and surgical instrument manufacturers having been requisitioned by the State, no source of supply was available for apparatus urgently required in cases of contracture, nerve paralysis, resection, and such conditions. On referring to the American Ambulance at Neuilly he obtained the services as technical director of Miss Grace Gassette, a Chicago artist of much mechanical ingenuity who had gained her experience in splints and bandaging at the Ambulance. Mrs. John F. Bass and Mr. E. Norman Scott, of Chicago, coöperated in finance and administration with the result that the production of surgical appliances on a large scale was rapidly brought to a high degree of efficiency. In the brochure Médecin Aide-Major G. Houzel describes the apparatus with abundant illustrations. Many of the splints are of familiar type, but the whole brochure forms an admirable survey of the field, and will well repay study by surgeons who have to deal with injured limbs and the correction of deformities. All the types of apparatus provided by the Comité are stated to be *déposés* or *brevetés*.

R. B. A. appears to have been misinformed.

Remarks
ON THE
PATHOLOGY OF WAR NEUROSES.

An Address given to the Officers at the Lord Derby War Hospital, Warrington,

BY JUDSON S. BURY M.D. LOND., F.R.C.P. LOND.,
MAJOR, R.A.M.C.(T).; CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

GENTLEMEN,—I appreciate very highly your kindness in asking me through Lieutenant N. Morris to give an address at one of your medical meetings, and let me take this opportunity to express to you my indebtedness for the hospitality and kindly welcome you have always given me on my Saturday visits. The choice of a suitable subject has been difficult because I wished to select one which would be of interest to representatives of each of the three great departments into which this large hospital is divided—viz., mental, medical, and surgical. It occurred to me that many of the so-called functional neuroses and also the reflex nervous disorders caused by injury have been observed by all of us, and that therefore it might be of interest to review our knowledge regarding at least some of them. These disorders, which have been very prevalent during the present war, were previously well known to us in civil practice; the difference is one of frequency rather than of kind.

The symptoms of the neuroses are: mental confusion, stupor, headache, irritability, loss of memory, insomnia, nightmares, hallucinations, obsessions, disorders of the special senses, disorders of speech, disorders of motor functions (such as tremors, convulsions, contractures, and paralysis), and disorders of sensation.

"FUNCTIONAL" AND "ORGANIC" NERVOUS DISORDERS.

At the outset let me say a word as to the difficulty of giving any precise definition of the terms "functional" and "organic."[1] These are commonly used in a pathological sense, being understood to imply the presence or the absence of some definite visible changes in nerve-tissue. But visibility is a relative term, it depends on our eyesight and the powers of our microscopes, and to some extent on staining reagents. Our methods of investigating nerve tissue are not infallible, and we must admit the possibility that even an emotion such as fear may produce minute changes in some of the cortical neurons.

If on grounds of convenience the terms "functional" and "organic" are retained, two points should be clearly recognised—(1) the term "functional" ought to mean not the absence of morbid changes but only the absence of detectable changes; and (2) it ought not to be taken for granted that a disorder which has no known structural changes will run a more favourable course than one in which such changes are apparent. The lesions underlying paralysis agitans, epilepsy, and dementia præcox are unknown to us, yet we can scarcely regard these diseases as curable. Death may result from a profound chemical disturbance of the atoms and molecules of nerve tissue which leaves no visible trace, and between such changes and those which are conspicuous there must be every gradation both in size and nature.

Such gradations are well illustrated by the results of a study of "war neuroses." These neuroses may be produced in at least three ways: (1) by the breathing of poisonous gases, especially carbon monoxide; (2) by concussion of the central nervous system the result of aerial compression caused by the explosion of a shell; and (3) by emotional disturbance. Frequently the neurosis is the result of a combination of these agents.

POISONOUS GASES.

First, with regard to carbon monoxide, Colonel F. W. Mott[2] has pointed out that if a man is buried under sandbags in a heavily shelled trench or dug-out, or if for any other reason he is confined in a small space in which the gas produced by an explosion collects, he will be rendered unconscious if he is not already unconscious as a result of concussion. In two fatal cases Mott found miliary punctiform hæmorrhages in the white matter of the brain, the result of inflammatory stasis and thrombosis of small arteries. If consciousness is regained the man appears dazed and stupid and may suffer for a long time from headache, loss of memory, mental confusion, disturbances of speech, and tremors.

CONCUSSION OF THE BRAIN OR COMMOTIO CEREBRI.

Apart from injuries received from fragments of a shell or from impact of the body against the ground or other solid substance, mere proximity to an exploding shell may be sufficient to cause detectable changes in the central nervous system.

In some cases the changes are severe enough to cause instantaneous death, probably owing to sudden arrest of the vital centres in the medulla from the enormous aerial compression; the force generated by 17-inch shells has been estimated as equal to 10 tons to the square yard. In other cases the changes are less severe and the man survives, but is subject to various symptoms indicating disorder of the nervous system. In many cases of shell shock the cerebro-spinal fluid withdrawn by lumbar puncture shortly after the shell explosion has shown increased pressure and has been found to contain evidence of the presence of blood, indicating that hæmorrhage had occurred.

Recently Mott[3] has published a report of the examination of the brains in two cases of death from commotio cerebri without visible external injury and without the punctate hæmorrhages indicative of gas poisoning. His description serves to explain sudden death in shell shock as well as the clinical symptoms which persist for some time in non-fatal cases.

One of his cases was that of a captain who for six months prior to his fatal attack had suffered from much nervousness, which, however, he had kept under control. Later he was in an area which was subjected to an intense bombardment during which no gas shells were used; this lasted about four hours. On the following day six shells came over. He was not buried or gassed. One shell burst about two feet behind him. His symptoms were coarse tremors of the limbs, inability to walk or to do anything, together with crying and other hysterical manifestations. On the evening of the same day he was admitted to the field ambulance in a state of acute mania. He was quieted with morphine and chloroform and slept all night. The next morning he woke up apparently well and suddenly died.

The brain was extremely congested and there were a number of minute punctiform hæmorrhages at the terminations of the smallest vessels on the surface of the brain, but there were no intracerebral hæmorrhages. The cerebro-spinal fluid was blood-tinged. On microscopical examination minute scattered subpial hæmorrhages were found almost everywhere. In the white matter of the corpus callosum, the internal capsule, the pons, and medulla there were congested vessels and hæmorrhage into their sheaths with occasionally extravasations of blood corpuscles into the adjacent tissue. The cells of the central nervous system showed early chromatolytic changes.

From a study of these changes Mott assumes that the cells of this man were in a state of commencing nerve exhaustion; some nuclei of the cells were more markedly affected than others—for example, the cells of the vago-accessorius nucleus. Mott correlates the maniacal excitement during life with the marked venous congestion of the cortex and the subpial hæmorrhages; the sudden death with the changes in the vago-accessorius nucleus, and the congested state of the medulla with hæmorrhage into the sheath of a vessel in the median raphe of the medulla. He thinks that the cerebral anæmia which was present and the chromatolytic changes in the nerve cells may explain many of the symptoms of sufferers with true shell shock—namely, headache, giddiness, insomnia, stupor, mental confusion, and terrifying dreams—symptoms which are so common in recent cases.

The group of symptoms is similar to that which we have all observed in civil practice from concussion of the brain as a result of blows or falls on the head. In both cases there is a contused condition of the cerebral cortex. In many respects the symptoms resemble those of severe non-traumatic neurasthenia.[4] But I think that certain differences may be observed. Instead of an uncontrollable tendency to discuss their symptoms in detail, sufferers from a bruised brain are dull and apathetic and show a tendency to drowsiness and stupor rather than to insomnia. The neurasthenic is able to commence work and to do it accurately for a time, but he soon tires, he lacks concentration, and exhibits indecision in all his actions. But the patient with a bruised brain is unfit to follow any employment; he is too apathetic, as a rule, to show signs of worry or anxiety, and when his cortical lesion is severe and extensive apathy may be associated with profound loss of memory and other signs of mental deterioration.

EMOTIONAL DISTURBANCE.

Thirdly, as to the effects of emotional disturbance apart from those of concussion or of the inhalation of poisonous gases. It is difficult for those of us who live quietly at home to visualise fully the terrifying conditions under which our comrades live at the front. When we think of the physical and mental strain of life in the trenches, of the shocks to the nervous system from the detonation of high explosives, together with the terror caused by the horrible sights of death and mutilation around, we are not surprised to find that the strongest nervous system may be exhausted or even shattered. How much greater and more frequent must be the effects of such terrifying surroundings on soldiers whose nervous systems, in consequence either of some previous illness or injury, or of an inborn neuropathic or psychopathic taint, offer less than normal resistance to emotional stress. As Hubert Norman [5] remarks: "The exciting factor is important, but still more important is the condition of the organism upon which it acts."

In this class of neuroses and psychoses the most careful examination of the patient, both soon after his breakdown and later at a base hospital, reveals no evidence of organic disease of the nervous system. It is, however, scarcely conceivable that great emotions should not produce some bodily change; recent experimental work, indeed, shows that definite changes do occur.

Effect on Sympathetic Nervous System.

The surface manifestations of pain and of great emotions, such as fear and horror, are well known to us. For example, "the contraction of blood vessels with resulting pallor, the pouring out of 'cold sweat,' the arrest of saliva so that the tongue cleaves to the roof of the mouth, the dilation of the pupils, the rising of the hairs, the rapid beating of the heart, the hurried respiration, and the trembling and twitching of the muscles, especially those about the lips."

But, as shown by the researches of Walter Cannon [6] and others, states of intense feeling are attended by disturbances not only in the superficial structures but also in deep-lying organs. These disturbances are similar to those brought about by great muscular exertion, and depend on nervous impulses to the sympathetic nervous system. Some of these impulses passing along the splanchnic nerves to the suprarenal glands lead to a pouring out of adrenalin into the circulating blood, which powerfully reinforces the action of the sympathetic nerves.

The result is that the vessels to the abdominal viscera are constricted, the blood pressure is raised, and the blood is driven from the abdominal viscera to the heart, lungs, brain, and skeletal muscles. Another effect of adrenalin is to transform the glycogen in the liver into sugar, which circulating in the blood gives renewed strength to the muscles. Moreover, adrenalin brings about a rapid recovery of muscle after its irritability has been lowered by fatigue, and it tends to neutralise or destroy the toxic substances produced by muscular or nervous work. During strenuous muscular action, especially if associated with emotional excitement, the respirations become rapid and forced in order to draw in more oxygen and to get rid of the excess of carbon dioxide. This ventilation of the lungs is much aided by the action of adrenalin in relaxing the smooth muscles of the smaller bronchial tubes.

In these various ways, then, muscular action is rendered more efficient by the changes in the viscera brought about by emotion. The shifting of blood from the abdominal organs to the organs immediately essential to muscular exertion—namely, the lungs, heart, and central nervous system—the increased vigour of the heart, the quick abolition of the effects of muscular fatigue, the mobilising of energy-giving sugar in the circulation, all help to render the organism more effective in the violent display of energy which fear or rage or pain may involve. Reservoirs of power are called forth which enable a man to perform feats of strength and endurance far beyond his normal capacity.

If the various energising substances—adrenalin, sugar, and probably also thyroid secretion—the products either of fear or of the fury and excitement of battle, are not worked off by muscular action it is conceivable that their presence in excess in the blood may lead to pathological effects; in other words, the cessation of physical exertion while strong emotions are dominant may be followed by a disordered action of both mind and body, which later, as when the soldier reaches a base hospital, is expressed by tremors, by tachycardia, by starting at the slightest noise, and by terrifying dreams of the horrors he has witnessed.

In severe cases the continued over-action of the suprarenal, and probably also of the thyroid glands, may produce a clinical picture similar to that of Graves' disease. Sometimes sugar is present in the urine. There is, indeed, clinical evidence that occasionally glycosuria and even diabetes may be originated by emotional disturbance. Schultze believes that the amount of glycosuria depends on the degree of mental depression, and that the greatest excretion of sugar occurs in the fear-psychoses.

Psychic Effect.

Now, the effects of emotional shock can scarcely be limited to the changes which, as we have seen, appear to be due to stimulation of the sympathetic nervous system. Surely, they must also produce some change in the neurons of the central nervous system. The exact nature of such change is unknown to us, and is not likely to be revealed by a microscopical examination of dead neuronic tissue. It is only by researches on the living neuron that we can expect to obtain any satisfactory knowledge.

Crile [7] has demonstrated by laboratory experiments that "in an animal driven strongly by emotion" there is a "mobilisation of the energy-giving compound in the brain cells, evidenced by a primary increase of the Nissl substance and a later disappearance of this substance and the deterioration of the cells." He says that the cell-changes due to the emotions are "so similar, and in extreme conditions approach so closely to the changes produced by disease, that it is impossible to say where the normal ceases and the abnormal begins." We have also to consider the association and dissociation of neurons which may occur, and which may be due to attraction and retraction of their dendrons. How, then, can we divide cases clinically into functional and organic?

In a consideration of the various agents that may originate and maintain a neurosis one factor—namely, repression—must not be overlooked. Fear must affect every soldier at some time or other during his life at the front. With many men, especially those who are highly strung, the fear of being afraid is always before them—the fear that they may fail at the critical moment to do what is required of them. (An interesting case is related by Professor G. Elliot Smith.[8]) The almost incessant efforts to repress such fear must have an injurious effect on the mental and bodily functions and tend to prepare the way for a nervous breakdown.

The result of repression of the emotions is often seen in men under treatment in home hospitals. The voluntary process of an attempt to remove painful memories and thoughts out of the field of attention, instead of being beneficial, may take an active part in accentuating the mental distress, in maintaining the neurosis, and also in the development of new symptoms. In some patients there is an attempt to banish from the mind feelings of shame due to their having broken down; in others grave apprehensions about fitness for further service, which are repressed owing to the idea that such thoughts are equivalent to cowardice, or might be so interpreted by others.

Rivers [9] points out that the advice usually given to such patients is that they should try to banish all thoughts of war from their minds, and they are instructed to try to think of other things such as beautiful scenery and other pleasant aspects of existence. Now, although there is much soundness in this policy, and although no one would advise the patient to concentrate his thoughts on painful memories or brood upon feelings of regret and shame, much harm may be done by an attempt to banish them wholly from the mind. If in place of thrusting aside such distressing thoughts the patient faces them boldly and talks openly with his doctor about them his general health is much more likely to improve, his power of sleeping to be increased, and his sleep to be less disturbed by terrifying dreams of warfare.

But for further discussion of this important subject and for records of suggestive cases I must refer you to Rivers' very interesting and valuable paper.

HYSTERIA.

Hitherto we have been mainly dealing with what I may call the pathogenesis of war neuroses. Now we may ask regarding the symptoms which we observe, Can they all be adequately explained by such bodily changes as I have mentioned; or have we to introduce other factors, especially

that subtle psychical condition which we call Hysteria? The subject of hysteria is very complex, and there are many views regarding the nature of this disorder. One of the most important is that of Babinski, who regards hysteria as essentially a matter of suggestion. He defines it as a pathological state manifested by symptoms which it is possible to reproduce exactly by suggestion in certain subjects, and which can be made to disappear by the influence of persuasion or counter-suggestion alone.

All the facts bearing on the development of hysteria have been admirably discussed by Babinski and Froment.[10] They review their own observations during peace and war, as well as the accounts given by trained observers who were present at times of great emotional stress, such as earthquakes, railway accidents, shipwrecks, and heavy bombardments at the front. They conclude—

"That emotion alone, however intense it may be, does not produce hysterical disorders, and although emotions may prepare the mind to submit to suggestion, they nevertheless exclude suggestion for the time being, and when they are intense they prevent the development of hysterical disorders or even cause them to disappear. When the human soul is shaken by a profound emotion there is no room left in it for hysteria."

One account which they quote is by Clunet, who was travelling on the transport *La Provence* at the time when she was torpedoed:—

Clunet saw no hysterical symptoms during the 17 minutes which elapsed before the boat sank, nor during the 18 hours he spent on a raft. There were manifestations of extreme emotion in the boat and of physical suffering on the raft, but it was not until they were picked up by a destroyer that some of the men showed paralysis, mutism, and other hysterical symptoms, all of which Clunet cured within a few hours by vigorous counter-suggestion, with such success that no relapse occurred during the eight following days whilst they remained under observation.

Similarly, real hysterical manifestations are rarely met with at the front. Emotional symptoms are common enough, men reaching the aid-posts weeping and tremulous, with rapid pulse and respiration. It is only at the base and in home hospitals that hysterical symptoms are common, the reason being that there has been time for suggestions to enter the mind during its recovery from a state of confusion. The particular symptoms that develop—whether paralysis, anæsthesia, mutism, or deafness—depend on the mental impressions received by the patient in consequence either of some morbid sensation of his own or of some circumstance attending the method of examination by his doctor.

The old conception of hysteria as held by Charcot and his contemporaries was very wide, and included a large number of disorders which are now known to have a different pathology. Babinski has done good service by trying to narrow this conception, and without attempting to discuss his theory of suggestion it will be useful to consider whether certain manifestations of these war neuroses which are still often regarded as hysterical may not be explained by physical rather than by psychical agency.

REFLEX NERVOUS DISORDERS.

I will limit my remarks to certain contractures and paralyses which develop after injury and which in their character, distribution, and associations present a close resemblance to the condition known as arthritic muscular atrophy. The fact that inflammation of a joint is almost invariably attended by rapid wasting of the muscles that cover the joint was first described by John Hunter. He recognised also that the atrophy is not the result of default of movement, for he says when the other limb is examined it is seen that the muscles there have preserved their volume, although they have not been more moved than the muscles of the diseased limb. He also noted that the muscles were sometimes paralysed, even when they were not atrophied.

Ollivier in 1869 was the first, I believe, to suggest the reflex nature of the phenomenon. Subsequently many theses and articles were published, including one by Charcot, who describes the condition with his usual lucidity and dramatic force. About 30 years ago I was much interested in this subject and in a published paper reviewed our knowledge concerning it.[11] Let me give a simple example.

A man injures his knee; it becomes painful and swollen; in a short time the muscles of the affected limb become weak and wasted, but both weakness and wasting are most marked in the quadriceps extensor. A measurement taken a week after the injury may show a difference of an inch between the girths of the thighs. The knee-jerk is exaggerated, and sometimes also on the unaffected side.

Other examples are: the wasting of the interossei and the muscles of the forearms in rheumatoid arthritis of the hands, of the deltoid in injuries of the shoulders, of the glutei in hip disease, and so on.

In explanation of these symptoms no better hypothesis than that of Charcot has yet been advanced—namely, that the nutrition of the motor cells in the spinal cord is damaged in a reflex manner, morbid influences being conveyed to them by the joint-nerves, and that their derangement or torpor determines the changes in the muscles. That the process is reflex was indeed shown by Raymond, who found that a previous division of the posterior spinal roots prevented the wasting of the muscles. In some cases the atrophy is persistent, and may spread to other muscles of the limb. I have seen cases which suggest that occasionally progressive muscular atrophy may be initiated in this way.

Now, curiously enough, these reflex nervous disorders, which may follow not only joint affections but also slight wounds to a limb or its injury by frostbite or in other ways, have been overlooked or discredited, and in many modern text-books on medicine there is little or no reference to them. The discredit into which the old views had fallen is largely due to the exaggerated development of the idea of hystero-traumatism—that is, to attribute to hysteria almost all the nervous disorders following traumatism and not due to a definite lesion of the nervous system. In their book Babinski and Froment have published important observations on these reflex neuroses and have given a full description of the atrophic paralysis and spasms which occur, and also of the other symptoms that may be associated with them—namely, increased excitability and slow contraction of muscles on mechanical stimulation, disturbances of sensation, of temperature, and of vaso-motor control as shown by coldness and cyanosis of the affected part, and, lastly, trophic changes in the bones and skin.

Several instances of these reflex disorders have come under my care during the present war. In Babinski and Froment's book will be found a number of completely new observations, as well as a discussion of the diagnosis of these disorders from other paralyses and contractures, whether they be of hysterical or of organic origin.

CONCLUSION.

In conclusion, I would emphasise the importance of recognising the gradual transitions that occur, both as regards symptoms and pathology, between emotional disorders and serious disease of the central nervous system. Think only of a convulsive seizure. Can the most experienced neurologist who watches it closely always tell whether it is due to malingering, to hysteria, or to epilepsy?

I would also draw attention to the similarity in symptoms that may be sometimes observed in functional and organic diseases. Cases of concussion of the central nervous system from shell explosion have been described which presented the symptoms of disseminated sclerosis, of cerebellar disease, or of general paralysis of the insane. Major Eager of this hospital, who has had such a large experience of mental disease, has told me that he is much impressed with the striking resemblance between the symptoms of some cases of shell shock and those of general paralysis. This suggests that similar groups of cortical cells are deranged in the two diseases; in the one by a specific poison which ultimately will lead to their complete destruction, in the other by the results of concussion or of profound emotional disturbance the effects of which may be expected entirely to pass away.

Lastly, we must remember the frequency with which hysterical manifestations may be grafted on to a basis of organic disease, and therefore the importance of making a thorough examination of every case which appears to be hysterical, in order that no sign of structural change may escape our notice.

GUNSHOT WOUNDS OF THE PERIPHERAL NERVES.

BY C. NOON, F.R.C.S. ENG.,

TEMPORARY MAJOR, R.A.M.C.; OFFICER IN CHARGE OF THE SURGICAL DIVISION OF THE NORFOLK WAR HOSPITAL.

BETWEEN June, 1915, and March, 1918, 364 cases of injuries of the peripheral nerves have been admitted to the surgical division of the Norfolk War Hospital. 250 cases have come under my observation, and of these 102 cases have required operative treatment.

Pre-operative and Post-operative Treatment.

The operative treatment in these cases should be looked upon merely as an incident in the treatment of the case. The most skilfully performed operation on an injured nerve is doomed to failure, and can accomplish little if the pre-operative and post-operative treatment is insufficient or neglected. The treatment in these cases should extend over a period of many months. The results can only be good when treatment is commenced early, and is conducted with great perseverance both on the part of the patient and on the part of those who are responsible for his treatment. It is often difficult or impossible in these cases to prevent complications and trophic lesions making their appearance, but if no attempt be made to prevent and overcome these conditions irreparable damage will supervene, damage which no amount of surgery can be expected to correct. It is most essential to try to make the patient realise the importance of treatment, and to make him understand how much he can do for himself to promote his recovery.

The treatment can be considered under the following headings:—

1. Postural treatment.
2. Electro-therapeutic treatment, including electric treatment, massage, and exercises.

Much has been written with regard to the positions which should be maintained after a patient has suffered a lesion of a peripheral nerve, but it must not be considered that everything has been done when the patient's hand or leg has been fixed in the orthodox position by some splint. It often happens that these cases are complicated by some injury to the bones of the limb. A splint is applied, fixing the whole limb. Of the many inventions for the treatment of fractures, and especially those complicated by nerve lesions, all are bad which hinder the easy movement of the phalanges of the thumb and fingers. If the hand or the foot is left fixed in any one position for long periods and passive movements are not frequently performed, disaster is certain to follow. It is quite as important to remove a splint often as it is to apply it at all.

The nutrition of the muscles must be preserved as much as possible by massage and electrical treatment. Vaso-motor lesions are of common occurrence in these cases, and it is often noticed that the limb affected is cold and clammy. It is most important to keep these limbs warm; especially is warmth important when electrical stimulation is being used as a method of treatment. It is futile to apply electrical stimulation to cold and blue extremities. The limb should previously be wrapped in warm cotton-wool, or immersed in hot water for a few minutes.

Joints must be prevented from getting stiff by passive movements, which should have been begun as early as possible. Cases of stiff joints will often be much benefited by hot-air baths.

The condition of the skin itself must not be neglected, but must be suitably protected from any injury. In short, every tissue innervated by the injured nerve must have due consideration and treatment. Treatment should be regular and continuous. If operative treatment becomes necessary massage should again start as soon as possible, and in the upper extremity every attempt should be made to prevent stiffness and contraction of the hand and fingers occurring.

A position of relaxation should be maintained in all nerve injuries.

In median nerve injuries the muscles supplied by the nerve are relaxed when the fingers and hand are flexed, and the thumb abducted and flexed, the arm being slightly rotated. Good results in this hospital have been obtained in cases of simple uncomplicated lesions of the median nerve without the application of splints.

In ulnar nerve injuries the muscles supplied by the nerve are relaxed, when the fingers are spread apart; the first phalanges flexed, the second and third extended, and the thumb abducted. Every attempt has been made to prevent contraction, and to maintain a position of relaxation in lesions of the ulnar nerve, by means of splints and appliancess, but more success has been obtained by massage and passive movements than has been obtained by methods of fixation.

In lesions of the musculo-spiral nerve, by means of a Jones's "cock-up" splint, or some modification of it, the hand is hyper-extended, the thumb abducted, and the arm put in a position of supination, so relieving the extensor muscles of all strain. Operations on the musculo-spiral nerve are doomed to failure if the paralysed muscles are allowed to become over-stretched and lengthened by allowing the wrist to be in the flexed position of "drop" wrist. If the wrist is kept in good position injuries of the musculo-spiral nerve are among the most favourable for treatment.

It is useful before leaving the question of massage, electrical and postural treatment, to answer the question: What can these methods of treatment do for a patient who has suffered a nerve lesion, and how long should such treatment be continued? Massage, electrical, and postural treatment can prevent joints becoming stiff. It can prevent muscular contraction to some degrees, and it can maintain the tone of the muscles; in other words, it can enable the parts to be kept in the most favourable condition for the resumption of their functions.

It can do little in late and neglected cases. One often sees hopelessly contracted limbs with paralytic deformities, and with muscles the seat of degenerated changes, sent to the massage and electrical department as a last resource. These cases should have been sent to this department for the prevention of these calamities, not for their relief, for the best massage and electrical treatment is often almost a waste of time in these cases.

It is difficult to lay down any definite rules and say how long treatment should be continued. Most cases show some improvement within six months. Massage and electrical treatment should be continued for at least six months after the operation on a nerve has been performed. It is unlikely that treatment for more than a year will give rise to much improvement.

Operation.

The operative procedure may be considered under the following headings:—

1. Skin incision.
2. Isolation of nerve trunk above and below site of lesion.
3. Freeing of nerve at actual site of lesion.
4. Passing the sutures and exact co-aptation of ends of divided nerve.
5. Formation of a sheath at site of lesion.
6. Suture of deep fascia and closure of wound.

An operation having been decided upon, it should be performed under general anæsthetic. The whole arm or leg to be operated upon should have been previously prepared with the utmost care, any lesion of the skin being an absolute contra-indication to the operation. It is a great advantage to have a third assistant, whose only duty it is to control the position of the arm or leg and hold it in any desired position. This is especially advantageous when operating upon such nerves as the musculo-spiral. The operation is best performed without the application of an Esmarch bandage. Any hæmorrhage which may occur is easily controlled by the application of forceps, and the wound, when closed, is left dry, there being much less risk of the development of any hæmatoma, a very undesirable complication.

The skin incision should be of ample length; for instance, in operating on the ulnar nerve in the forearm it is best to make an incision from just below the elbow to just above the wrist; the skin having been divided its edges are protected by thin rubber sheeting or gauze attached by means of clips. If possible the skin incision should be planned so that it avoids the old scar or the scar should be excised. Excision or freeing the scar should always be practised wherever possible, the deep fascia is next divided, and any bleeding points controlled.

The nerve trunk is sought above and below the point of severance, and it is traced downwards and upwards to the lesion. In doing this the tissue surrounding the nerve should

be dissected away from the nerve, and the nerve itself should be handled as little as possible. On exposure of the injured part of the nerve a bridge of fibrous tissue is usually found joining the ends together; it is best to dissect this quite free before attempting to determine whether the nerve has been divided or not, so that when the nerve has been completely freed its continuity has not been divided during the operation. The fibrous tissue is then dissected off the nerve, and a decision arrived at as to the pathological condition present. When the conclusion is arrived at that the nerve has suffered anatomical division, and its ends are only joined by a fibrous band, one very fine silk suture is passed vertically through healthy parts of the upper and lower ends of the nerve to be joined. This suture is a great aid in maintaining the exact co-aptation of the nerve, when suturing it after removal of the intermediate fibrous tissue. Different bundles of the nerve have different functions, so it is most important to bring the corresponding bundles together in the suturing. The nerve at the site of the suture should be handled as little as possible.

After the primary suture has been inserted, the supposed fibrous band is divided, and sections are cut from its distal and proximal ends until nerve fibres are seen. The primary suture is then tied, bringing the ends of the nerve into exact apposition; a series of sutures unite the nerve-sheath. It is most important to avoid tension.

I use the finest silk and the finest needles for suturing the ends of divided nerves. Catgut is the material usually recommended. It appears to me that the exactness and security of the junction are more important than the suture material used to perform and make it.

The necessity of the formation of a sheath at the site of junction has next to be considered. The nerve after suture should be placed in a bed of healthy tissue; if this can be done it will not be necessary to surround it with any foreign tissue.

Much has been written with regard to the surrounding of sutured nerves with some material supposed to have protective virtues—a piece of fat, a piece of vein, Cargile membrane, a piece of peritoneum from a hernial sac, have all been recommended. A piece of fat of moderate thickness cut from the patient's own thigh, and loosely sutured round the nerve so as to protect the site of suture, makes an ideal covering and bed when much scar tissue is present.

If the operation is done aseptically the procedure has everything to recommend it. It is advised by many surgeons and condemned by others, but the researches of Bittorf appear to prove that it is a sound and scientific procedure. It is doubtful if the aseptic introduction of a piece of the patient's own fat can ever be harmful; it is almost certain that it is often of great service.

On completion of the suture any bleeding points are carefully tied with catgut and the wound thoroughly irrigated with warm saline solution. The deep fascia is carefully sutured with catgut and the wound closed without drainage. The arm or leg is then carefully bandaged. The limb should be placed in the best position to relieve the nerve from tension, and it should be fixed in such a position by splints and bandages. Massage for the hand should be started two or three days after the operation.

Complications.

The chief complications met with in this series of cases have been:—

1. Those due to septic infection of the wounds, extensive destruction of the soft parts, and severe injuries to the bones.

2. Extensive destruction to the nerve, resulting in a gap in its continuity, making end-to-end suture impossible.

1. Drainage and rest for the inflamed parts have been relied on chiefly to overcome the septic complications. With thorough drainage the wounds have usually healed well and given rise to little trouble. In a certain number of cases of severe infection, associated with marked swelling and œdema of the limb, it has occasionally happened that owing to the pain it has been impossible to prevent some stiffness of the fingers, due probably to the inflammation spreading to the tendon sheath. In such cases, after all the signs of inflammation have disappeared, it will be found that much benefit will be derived from gentle but firm movements of the parts under an anæsthetic.

In cases associated with compound fractures very careful treatment is necessary if necrosis with the development of a persistent sinus is to be avoided, which may delay the suture of the nerve for many months. These cases should be thoroughly drained at the earliest possible date, and all loose pieces of bone which have not firm attachment to periosteum removed. A healed wound must be obtained at the earliest possible time in cases of compound fracture, complicated by nerve lesions. Carrel-Dakin treatment or continuous irrigation should be used as a method of treatment when necessary.

2. Extensive destruction of the nerve, resulting in a gap in its continuity, making end-to-end suture impossible.

End-to-end suture is the operation of choice. It should be done whenever possible, It will usually be found possible to perform end-to-end suture after considerable pieces of nerve have been destroyed, if sufficient attention be paid to the following points:—

(1) The incision should be of ample length, so that the nerve may be separated from the surrounding structure, both above and below the lesion. (2) In lesions of the ulnar nerve it can be displaced in front of the internal condyle of the humerus. (3) During and after the operation the position of the limb should be put in that of maximum relaxation, so that all tension is taken off the nerve.

When it has been found impossible to perform end-to-end suture a variety of procedures have been attempted and advised, but it would appear that up to the present time authorities have not been able to determine the values of these operations, but from various writings it would seem that their value is not great, and that for a few successes there are many failures. Some of the procedures would, on general principles, seem quite useless. The operation for uniting the ends of nerves by cutting flaps has been condemned as useless, but I have observed this method is sometimes followed by success.

Under certain circumstances nerve suture may be replaced or supplemented by tendon transplantation—namely: (1) when nerve suture is impossible; (2) when the functional result attained by nerve suture is unsatisfactory. The most favourable cases in which to prepare tendon transplantation are those of injury to the musculo-spiral and posterior interosseous nerves. The transplantation of the tendon of the flexor carpi radialis through and into the tendons of the extensor longus pollicis, the extensor brevis pollicis, and the extensors of the fingers, is an operation followed by such good results that it should always be done in cases when it is considered likely that the musculo-spiral nerve will not recover. "Complete restoration of function may be expected in four weeks—an enormous saving of time compared with the year which must elapse before recovery after nerve suture" (Murphy).

Conclusions.

From a study of these cases the following are the conclusions arrived at:—

1. That the diagnosis of an injury to a peripheral nerve ought to be made at the earliest possible time.
2. Successful recovery depends upon early, correct, and continuous treatment.
3. Primary suture should be considered and practised whenever possible.
4. That there should be no unnecessary delay in exploring a nerve if there is sufficient evidence that it has received some injury resulting in a macroscopic pathological lesion.
5. It is almost certain that some macroscopical lesion is present in cases which show no signs of recovery after four months' treatment.
6. That operations on injured nerves should only be done in well-equipped general hospitals, and by those surgeons who have ample experience of such cases.
7. That sufficient attention is not usually paid to the early pre-operative and post-operative treatment, and that paralytic deformities and shortened muscles are often the result of ignorance and neglect.
8. That the extreme gravity of an injury to a peripheral nerve is not sufficiently realised by the general profession.

I wish to acknowledge my indebtedness and appreciation to Colonel T. H. Openshaw, consulting surgeon to the Eastern Command, for his advice in some of the more difficult cases; and I also desire to thank Major A. J. Cleveland and his staff in the electro-therapeutic department of the hospital for numerous suggestions in the treatment of the cases.

GUNSHOT WOUNDS OF THE THORAX: THEIR LATER STAGES.

BY J. A. WILSON, M.D. GLASG.,
RESIDENT SURGEON, THE LORD DERBY WAR HOSPITAL, WARRINGTON.

SOME of the men who receive gunshot wounds of the thorax die on the field of battle, some in hospitals abroad; others filter through these hospitals and reach the hospitals at home. Those who come home include the less serious cases. The following table and notes deal with 50 of these cases—that is, with the later or terminal stages. On an average the cases were admitted 18 days after being wounded. Wounds of entrance: chest 19, back 12, shoulders 8, sides 7, neck 4.

No.	Non-penetrating.	Penetrating.	Through-and-through.	Hæmothorax.	Aspirated.	Resected.	Metal removed.	Metal still in.	Pneumonia.	Discharged to duty.	Employments III.	Medical boarded.	Died.

Non-penetrating.—Seven cases of wounds of thoracic wall did not penetrate pleura. Two of these had hæmoptysis, 4 had hæmothorax; of latter 2 manifested pleuritic friction. One had a small swelling over ribs due to incarceration of piece of cloth; here also pleuritic friction was heard over adjacent area. This came on late in course of illness, probably due to extension of inflammation. One developed pneumonia and another a persistent form of basal congestion or bronchopneumonia. Thus, concussion may cause hæmoptysis, hæmothorax, or pneumonia.

Penetrating wounds.—Most of these had hæmoptysis, some for several days after they were wounded. Several state quite definitely that they did not spit blood and yet they presented physical signs of effusion. In 8 cases ribs were broken, in 4 scapula, in 2 humerus (1 requiring amputation at shoulder), in 1 clavicle. In 1 vertebræ were damaged; in 1 œsophagus was slightly damaged. In 3 pleura had been sewn up, in 1 diaphragm. In 16 cases the wounds were through-and-through; some of these had only short tracks through lungs. Several did not present any physical signs of hæmothorax. In 13 cases resection of rib was done for empyema. Several had physical signs of contralateral disease of lung or pleura, conditions very well described by Sir J. R. Bradford.[1] Several cases with the physical signs of effusion were not aspirated, as there were no indications of sepsis; physical signs gradually disappeared. Pleuritic friction was frequently heard in the later stages.

Twenty-eight, or more than half, returned to duty in from 2 to 4 months; 6 were discharged to Employments III. and 14 from the Army by medical boards, 6 in consequence of empyema, 4 in consequence of still having metal in lungs, and 4 because of disabilities due to other injuries. One man had a sinus two inches deep between lower ribs, left by some operative procedure, and into this iodoform and bismuth paste was injected; immediately coughing was provoked, and within a few seconds he coughed up pieces of paste size of pea. Sinus healed in a few days. Two patients died from septic pneumonia.

1. Came in with small wound above left clavicle. X rays revealed ragged piece of metal deep in neck, probably in apex of lung.
2. Gunshot wound in back, caused by piece of metal striking glancing blow near inferior angle of scapula. When admitted—four weeks later—right lung was dull and crepitant. Sputum blood-stained. Died three weeks after admission from double septic pneumonia.

Both these cases had septic flesh wounds other than those over the lungs. This association is suggestive of danger.

The operations required at this hospital were performed by Major G. Sichel, now in France, but then senior surgeon.

ABSTRACT OF A PAPER ON

CAPSULATE MUCOID FORMS OF PARATYPHOID AND DYSENTERY BACILLI.

BY WILLIAM FLETCHER, M.D. CAMB.,
CAPTAIN, R.A.M.C.; PATHOLOGIST, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR, FEDERATED MALAY STATES.

(From the Laboratory of the University War Hospital, Southampton.)

DURING routine examination of excreta of two chronic paratyphoid carriers I have met with some curious capsulate bacilli which form large mucoid colonies on Endo's fuchsin-sulphite-agar, totally unlike those of *B. paratyphosus B*, but which proved to be a variety of that organism. I have also encountered similar organisms in a case of infection with *B. aertryck*, and in convalescents from dysentery of the mannite-fermenting group.

I have not found them in typhoid, paratyphoid A, or in dysentery of Shiga type. Such cases have been few in number, and possibly they may yet be found; indeed, Professor Tanner Hewlett has suggested to me that all the members of the coli group may have this Proteus-like power of disguising themselves, and he has drawn my attention to a paper by Cecil Revis.[1]

Revis found that when a sample of soil contaminated with human fæces was first sterilised and then inoculated with a certain culture of *B. coli* "very large, jelly-like, clear colonies," quite unlike ordinary *B. coli*, developed at the end of four months. These colonies gave the usual fermentations of *B. coli*, and "on microscopical examination the bacteria were seen to be embedded in a cementing substance." When they were subcultured it was found that "the typical form and the new type seem to be quite dynamic, passing readily from one to the other."

I have had no opportunity of conducting experiments on animals, but I am publishing this account without waiting to do so, because it is important they should be recognised. In addition to Professor Hewlett, I am indebted to Lieutenant-Colonel D. Harvey, Major F. W. Andrewes, and Captain A. C. Inman for examining several of the cultures, to Dr. Doris MacKinnon and Miss Gertrude Long for drawings and charts, and to Dr. Alex. Hill for allowing me to make photographs at the Southampton University College. I shall be most happy to supply other workers with subcultures.

Paratyphoid Mucoids.

In the spring of 1917 the fæces were examined daily of a number of soldiers from whom paratyphoid bacilli had been isolated during convalescence, to determine if the place of the pathogenic bacilli is taken by any special organism, or group of organisms. I hoped that, if the paratyphoid bacilli were crowded out during convalescence, such an organism might be of benefit in treating carriers; a forlorn hope, one must admit.

Pte. S., a chronic paratyphoid carrier, was taken ill at end of August, 1916. His excreta were examined many times. When an emulsion was plated direct on to Endo's fuchsin-sulphite-agar from

[1] Centralblatt für Bakteriologie, 1910, 26

51 to 100 per cent. of colonies were paratyphoid. 116 samples of fæces had been examined; the 116th sample gave 100 per cent. of paratyphoid colonies. In the 117th percentage dropped to 10; a new type of colony appeared, consisting of large, slimy, white, mucilaginous colonies which I have named "Mucoids." During the next 11 days the fæces were examined seven times; average percentage of paratyphoid colonies only 11; mucoids were present in large numbers on each occasion. On twelfth day no mucoids found on plate; percentage of paratyphoid colonies rose once more to 50. (See Chart.) The mucoids

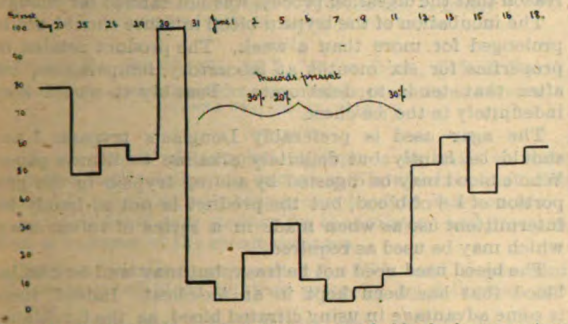

Chart showing percentage of ordinary paratyphoid colonies present on Endo plate and the fall in percentage when mucoids were present. The proportion of mucoids is given for those days on which it was recorded.

were not found again in seven subsequent examinations, and the paratyphoid colonies were as numerous as ever. The sum percentage of mucoids and paratyphoids is approximately equal to percentage of paratyphoid colonies usually seen when no mucoid organisms are present.

Subcultures were made and usual media inoculated. The organism reacted in same fashion as *B. paratyphosus B*. When first isolated the organism was not agglutinated by a paratyphoid serum, but it did absorb the agglutinins from it. When this strain of mucoids was re-tested eight months later it agglutinated slowly and imperfectly in low dilutions.

One day, when I had wished to prepare a fresh culture from a single mucoid colony, I plated out some peptone-water inoculated five days before. The result was a mixture of mucoids with ordinary paratyphoid colonies. I thought I was working with a contaminated culture. Further investigation proved that the paratyphoid colonies had originated from the mucoid form. If a culture of the mucoid be inoculated into peptone-water and plated every day there will be a few ordinary paratyphoid colonies on plate made on third day; on fifth day they will be in majority. The mucoid colonies give rise to ordinary paratyphoid bacilli.

[Experiments undertaken to test purity were here described.]

with them, like ground glass. If the latter be subcultured several times they will give rise to the luxuriant large mucoids once more.

I have never yet succeeded in obtaining mucoids from the ordinary form. Cecil Revis, it will be remembered, found that his "jelly-like" *coli* colonies passed readily from one form to the other.

In mucoid colonies 24 hours old many of the bacilli measure from 1·5 to 2·5 μ; there is a large number of small coccoid forms 0·75 to 1 μ in diameter. The general appearance of a film made from one of the paratyphoid colonies derived from the mucoids is very different. These derived bacilli are, for the most part, larger; the small coccoid bacilli, so numerous in mucoid films, are rare; very long "involution forms," from 12 to 45 and even 100 μ in length, are the most striking feature.

When a culture of the mucoid form in peptone water is examined by the dark-ground method the number of small cocco-bacilli at once catches the eye, and the rapidity with which these coccoid forms travel is very striking.

When films of the mucoids and of the derived colonies are stained by Benians' "relief stain," [2] the two can be distinguished at a glance. The picture is quite different from that given by ordinary staining methods; there the bacilli in mucoid cultures are smaller than those in the derived; here, on the contrary, the silhouettes of the mucoid organisms are much the larger. The explanation of this is that they have capsules, while the paratyphoid bacilli in the derived colonies have none.

In films made from the mucoids the faint outlines of the bacilli can be distinguished lying within thick capsules, and there are many round, coccoid forms about 3 μ in diameter. The capsules cannot be stained by ordinary means, such as Welch's method, and it is possible that they are not firm envelopes, but are derived from the mucoid matrix in which the bacilli are embedded and envelop them as drops of dew envelop particles of dust.

There is yet another point of difference between films made from mucoids and those from the derived paratyphoid colonies. In the latter the background of Congo-red is homogeneous, but in mucoid films it is traversed in all directions by an irregular reticulum composed of a deposit of small granules, which appears to be derived from mucilaginous matrix. This deposit is not shown in Fig. 2.

The evidence in favour of classifying these mucoids as a form of *B. paratyphosus B* is overwhelming.

The mucoid organisms disappeared from the excreta of Pte. S. on June 11th, 1917, and shortly afterwards he was transferred to another hospital.

From that time until Oct. 6th only six carriers of paratyphoid bacilli were admitted to this hospital; none a chronic carrier; no mucoids found in excreta. On Oct. 6th Pte. C., a chronic carrier of *B. paratyphosus B*, was sent here from France.

He had been taken ill on Sept. 1st, 1917; severe attack with high fever and hæmorrhage from bowels. He had received two injections, by T.A.B. 2 method, 1½ years before illness.

In first plate, prepared from fæces, a large number of mucoids was present. The mucoids did not disappear; in 59 examinations made while he was here they were found 47 times. Ordinary *B. paratyphosus B* always present as well. As a rule, 80 per cent. of colonies on Endo plate, spread with emulsion of fæces, consisted of mucoids and typical paratyphoid colonies.

Illustrations of Mucoid Forms of Paratyphoid Bacilli.

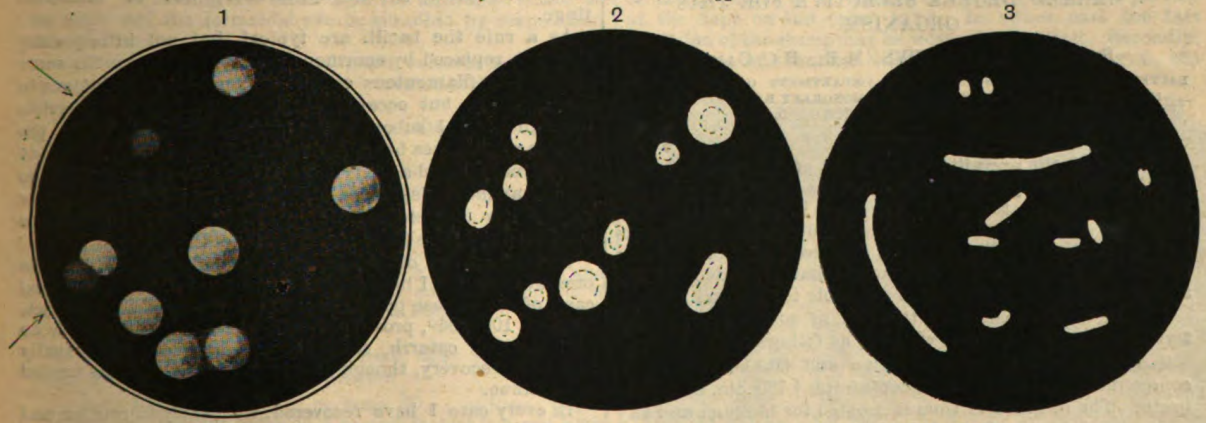

FIG. 1.—Sketch of five-day peptone culture of mucoid isolated from fæces of Pte. S., plated on Endo's medium. The large colonies represent the mucoids, the small colonies (to which the arrows are directed) consist of paratyphoid organisms derived from them.
FIG. 2.—Drawing of silhouettes of mucoid organisms in case of Pte. S. (Benians' stain.) × 2000.
FIG. 3.—Drawing of silhouettes of paratyphoid bacilli derived from mucoids. (Benians' stain.) × 2000.

The only way in which these paratyphoid organisms derived from mucoids differ from typical paratyphoid bacilli is: (*a*) the colonies on solid media are, as a rule, more granular; (*b*) more long "involution forms" are present than usual. Subcultures from these derived colonies behave in every other respect like ordinary paratyphoid organisms.

The mucoid colonies have about twice diameter of ordinary paratyphoid colony, and after repeated subculture on successive days they may attain a diameter of more than 1 cm. in 24 hours. They are dome-shaped, circular in outline, with a regular margin, and a mucoid appearance absolutely unlike a paratyphoid colony. By transmitted light they are very translucent and are somewhat like frosted glass.

A fresh culture on an agar slope is thick and slimy-like mucus. In a few days the sliminess disappears, except near top of tube, and on re-plating some ordinary paratyphoid organisms derived from the mucoids are found. If a culture on agar be left for several weeks and then plated the resulting growth will consist almost entirely of non-mucoid paratyphoid colonies and a few minute ghostly colonies mingled

The mucoid organisms resemble those of Pte. S., with the important exception that they do not remove the specific paratyphoid agglutinins from an immune serum saturated with them.

If a tube of peptone-water or other medium be inoculated with a culture of Pte. C.'s mucoid and incubated for several days the mucoids give rise to ordinary paratyphoid bacilli, which are not only agglutinated to full titre by a paratyphoid serum, but also remove the specific agglutinins from it by absorption.

A very glutinous variety of mucoid was isolated on one occasion from fæces of Pte. C. These glutinous colonies differ only in their small size and their stickiness. Both the mucoids and the glutinoids are precursors of the ordinary form under the conditions employed.

[2] T. H. C. Benians: Brit. Med. Jour., Nov. 25th, 1916.

Aertryck Mucoids.

These mucoid organisms were isolated from another patient.

Pte. W. suffered from acute infection with *B. aertryck* of "Mutton" type, ascribed to infected pork-pie. Typical Aertryck bacilli were isolated five times from fæces, once from urine.

Mucoid bacilli were recovered from fæces once only, at beginning of third week. This mucoid organism is motile, Gram-negative, does not liquify gelatin or produce indol. It turns milk acid in 12 hours and alkaline after four days. Its fermentation reactions in lactose, saccharose, glucose, maltose, mannite, dextrin, and dulcite are identical with those of *B. aertryck*.

When first isolated emulsions of mucoid organisms were not agglutinated by an Aertryck serum, nor did they absorb the specific agglutinins from it. When a culture in peptone-water, which has been growing for a few days, is plated on Endo's medium there are colonies of ordinary Aertryck bacilli mingled with mucoid colonies. The bacilli in colonies derived from mucoids behave in every way like typical *B. aertryck* of Mutton type.

One must conclude, therefore, that there is a mucoid form of *B. aertryck* as well as a mucoid form of *B. paratyphosus B.*

Organisms of the Mucoid Type in Dysentery.

Mucoid colonies have been found in four carriers of *B. dysenteriæ* (mannite-fermenting) and in one convalescent from dysentery, but from whose excreta dysentery bacilli were never isolated.

These mucoids differ in many respects from those found in paratyphoid infections. On an Endo plate spread with emulsion of fæces and incubated for 24 hours the mucoid colonies are about twice the size of usual dysentery colony. On plates made from subcultures they are smaller and reduced to little yellow droplets, which in 24-hour culture adhere to platinum loop and can be removed bodily from surface of medium without leaving a trace behind. In older cultures they become very adherent. Subcultures on agar slopes are hard, rough, and tenacious, with a yellowish colour.

After subculture of these mucoids in peptone-water, bacilli which resemble ordinary dysentery bacilli appear amongst the mucoids. These bacilli are derived from the mucoids.

These derived bacilli are agglutinated by immune sera of Flexner-Y type, but they do not absorb the specific agglutinins for homologous cultures or for typical dysentery bacilli isolated from same patients.

Neither the mucoids isolated from these dysentery convalescents nor the non-mucoid strains derived from them have been shown to be true dysentery bacilli.

ON A METHOD OF

PREPARING MEDIUM FOR THE CULTURE OF PFEIFFER'S INFLUENZA BACILLUS

THAT GIVES PROFUSE GROWTH AND IS TO A MARKED DEGREE SELECTIVE FOR THIS ORGANISM.

BY JOHN MATTHEWS, M.B., B.C. CAMB.,

BACTERIOLOGIST AND ASSISTANT TO DEPARTMENT OF THERAPEUTIC INOCULATION, ST. MARY'S HOSPITAL; HONORARY BACTERIOLOGIST, STAR AND GARTER HOME, RICHMOND, ETC.

IN view of the prevailing pandemic of influenza it seems a fitting time to publish a short account of this peculiarly valuable medium, though it has been in contemplation to publish a more complete paper with detailed experiments and illustrations. The medium, however, is so favourable for the culture of influenza bacilli that it is deemed inadvisable to delay in making it available for general use.

The method consists in the use of blood digested by trypsin, the preparation of which is as follows:—

Quantities of 0·25 c.cm. of Allen and Hanburys trypsin compound are added to tubes containing 4·75 c.cm. of sterile broth. The mixture is then incubated for 24 hours and any contaminated tubes discarded. 1 c.cm. of blood from a venipuncture is then introduced into each tube, and the mixture of trypsin, blood, broth is incubated for three or four days. The product is then ready for use and is mixed with agar, as if making ordinary blood agar, in the proportion of 5 c.cm. of trypsin-blood mixture to about 30 c.cm. of agar. The trypsinised blood can be used in larger proportions than indicated, with advantage, if large quantities of emulsion be required. My colleague, Captain A. F. Hayden, obtained extraordinarily thick growths by using trypsinised sedimented corpuscles.

The advantage of the proportions indicated, however, is that they are just those quantities arrived at when making diagnostic blood cultures by the method of Douglas and Colebrook.[1] Thus any blood cultures that may prove sterile form ideal material for the medium in question, instead of being a waste product. Indeed, it was by the use of such material that the value of the method was discovered.

It may here be noted that Captain S. R. Douglas suggested the use of trypsinised medium about the date of the paper referred to, but the experiment failed at that time for the reason that the digestion process was not carried far enough.

The incubation of the trypsin-blood mixture should not be prolonged for more than a week. The product retains its properties for six months at laboratory temperature, but after that tends to deteriorate. Possibly it would keep indefinitely in the ice-chest.

The agar used is preferably Douglas's trypagar,[2] and should be faintly but definitely alkaline to litmus paper. Whole blood may be digested by adding trypsin in the proportion of 1–4 of blood, but the product is not so handy for intermittent use as when made in a series of tubes, one of which may be used as required.

The blood used need not be fresh, but may well be citrated blood that has been kept in an ice-chest. Indeed, there is some advantage in using citrated blood, as the trypsinisation seems to proceed more rapidly when citrate is present than when fresh blood is used.

The medium grows influenza freely from the first culture, and it is to a marked extent selective. Thus, it inhibits pneumococci entirely and in a large measure streptococci and other Gram-positive organisms, but apparently favours staphylococci.

It grows the Gram-negative cocci of the catarrhalis group, together with bacilli of the coliform group, freely, but does not favour them in the way it favours influenza bacilli.

The colonies of these bacilli on initial cultures attain a large size, being frequently 3 mm. broad; they are at first hemispherical, and later tend to be flat, and are translucent, with a brownish tinge and a regularly circular outline. The colonies of the catarrhalis group are usually more opaque, more convex, and more deeply tinted; staphylococcal colonies are white. Subcultures usually give quite confluent growths, frequently of the profusion of a typhoid culture, with a similar greasy appearance, but of brownish tinge.

As a rule the bacilli are typical, but not infrequently they are replaced by enormously long filaments. To some extent this filamentous condition depends on variations in the medium, but occasionally the characteristic persists through several subcultures on the special medium, the growth at all times being typical when subcultures are made on ordinary blood-agar. These strains do not emulsify so readily as the typical ones, and subcultures are apt to show only a few discrete colonies, possibly on account of the matting due to the filamentous forms of the organism.

It may not be out of place to record that during the present epidemic I have investigated about a dozen typical cases of the disease presenting these features—sudden onset, fever of 103–104°, prostration and malaise, usually with no symptoms of catarrh, and followed by rapid and usually complete recovery, though in some the malaise has tended to continue.

In every case I have recovered, frequently in profuse and practically pure culture, Pfeiffer's bacillus when making use of West's post-nasal swab, which method I almost invariably use, planting the swabs direct on to plates of trypsinised blood-agar. In the cases where catarrh has been present I have found the bacillus in bronchial and nasal mucus, together with varying quantities of pneumococci and streptococci, as shown by ordinary blood-plates. One case of nasal catarrh gave a pure culture from the nose as well as from the post-nasal space. No single organism, with the exception of Pfeiffer's bacillus, has been invariably—or perhaps frequently—present.

I feel confident, therefore, that if this medium be used, and especially if the post-nasal space be explored, Pfeiffer's bacillus will be found universally associated with the epidemic.

USEFUL MEDIA

FOR ISOLATION AND CULTIVATION OF MENINGOCOCCUS, ENTEROCOCCUS, AND *B. TYPHOSUS*.

BY W. JAMES WILSON, M.D. R.U.I., D.SC. BELF.,
MAJOR, R.A.M.C., T.F.; DIRECTOR OF PUBLIC HEALTH LABORATORIES, QUEEN'S UNIVERSITY, BELFAST; SPECIALIST SANITARY OFFICER, BELFAST MILITARY DISTRICT;
AND
GEORGINA DARLING, M.B., B.CH. DUB., D.P.H. BELF.,
DEMONSTRATOR IN HYGIENE AND PUBLIC HEALTH LABORATORIES, QUEEN'S UNIVERSITY, BELFAST.

As the result of personal experience we wish to draw attention to the following culture-media which in our hands have shown definite advantages over those in common use.

1. *Laked-blood agar medium* for the isolation and preservation of cultures of the meningococcus.

To fluid nutrient agar cooled to 50° C. add 3 per cent. of sterile laked-blood mixture prepared by following procedure:—

A wide-mouthed sterile bottle with volume graduation marks has added to it 10 g. of sodium citrate dissolved in 10 c.cm. of water and is taken to slaughter-house. When a sheep is being slaughtered the blood after the first gush is received into bottle usually up to 1 litre mark; during process bottle is vigorously shaken. On arrival at laboratory 1·25 c.cm. of formalin are added to litre of blood and thorough admixture ensured. The blood is then transferred with aseptic precautions to a ground-glass stoppered bottle and 30 c.cm. of methylated ether are added to one litre of blood. Stopper firmly inserted and bottle shaken; then left overnight in incubator at 37° C.

When required 3 c.cm. of mixture are added by pipette to fluid agar at temperature of about 50° C. It is convenient to have agar stored in flasks of 100 and 200 c.cm.

If immediately required the blood agar is kept at 50° C. for one hour before being poured out into plates or tubes so that ether may be driven off. The same result can be more conveniently obtained by incubating plates overnight at 37° C.; this also tests sterility.

This method of obtaining sterile blood was suggested to us by the work of Fildes and Rajchman[1] and of Bernstein and Epstein.[2] It is in the main a combination of the advantages of both. In making the blood agar the antiseptic action of the ether and the formaldehyde is annulled by evaporation and dilution.

Experiments have shown that fresh cultures may be kept alive on this medium for from 6 to 9 months at 37° C. without transplantion.

This medium is also useful for the cultivation of *B. influenzæ* and anaerobes.

2. *Modification of the Conradi-Drigalski medium.*—The following modification gives excellent results:—

Nutrient agar containing 0·5 to 1 per cent. of lactose is stored in 100–200 c.cm. flasks. To 100 c.cm. of melted agar cooled to 50° C., 3 c.cm. of etherised blood mixture, 1 c.cm. of 0·1 per cent. crystal violet, and 12 c.cm. of Kubel and Tiemann's litmus solution are added, and the medium is poured out into plates which are then incubated overnight to drive off the ether.

3. *A brilliant green lactose bile-salt agar medium.*—The medium has the following composition:—

Lemco 10 g., agar 30 g., peptone 20 g., sodium taurocholate 5 g., sodium chloride 5 g., and lactose 5 g. per litre. Reaction of medium is adjusted to + 10 (Eyre) and 0·4 c.cm. of 1 per cent. solution of brilliant green added to each 100 c.cm. of melted medium which has been cooled to 50° C. and is ready for pouring out into plates.

The adjusting of reaction is the most important point in its preparation. If more acid is added specific inhibitory action on *B. coli* is annulled; and if medium is made more alkaline growth of *B. typhosus* is retarded. Many strains of *B. coli* completely fail to grow on this medium; others grow slowly and others quite readily. It is observable that, after a few strains of *B. coli* have grown, subsequently other colonies develop, the acid produced by the first strains evidently reducing inhibitory action of brilliant green on the others.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON RE-AMPUTATIONS.

BY W. A. CHAPPLE, M.D., CH.B.N.Z., M.R.C.S., D.P.H.,
MAJOR, R.A.M.C.; PAVILION ORTHOPÆDIC HOSPITAL, BRIGHTON.

TWO facts are of great and increasing significance in the surgery of amputations, and the accompanying illustrations from a case under my care may serve to emphasise these facts. In the first place, it is impossible to re-amputate in the presence of pus if the ordinary

FIG. 1.—Stump showing projecting bone on May 10th, 1918, primary amputation having been performed on March 22nd, 1918.

sutures are used without great sacrifice of length of bone, on the one hand, or a certainty of breaking down and parting of the flaps on the other hand. In either case the last condition of the stump may be worse than the first. Secondly, by the use of "button sutures," as shown in Fig. 2, the

FIG. 2.—The same stump four days after operation on May 11th, 1918. Dead bone has been removed, but the whole of the skin flaps retained.

following advantages are obtained: (*a*) earlier operations can be undertaken, with the saving of weeks and even months of time; (*b*) length of bone can be saved; and (*c*) primary union can often be secured, and earlier union almost always, and this notwithstanding the presence of pus both before and after the operation.

[A third illustration supplied by the author has been omitted out of consideration for space. This photograph demonstrated that the edges of the wound did not break down, but that, on the contrary, union took place in 12 days.]

A NOTE ON LICE AND SKIN DISEASE.

BY J. F. SMITH, M.B.,
CAPTAIN, R.A.M.C. (T.C.); OFFICER IN CHARGE, SKIN DEPARTMENT, —— GENERAL HOSPITAL, FRANCE.

ATTENTION has recently been directed by Captain H. C. Semon and Captain H. W. Barber to the importance of pediculosis as a cause of cutaneous disease in the Army.[1] While it has always been recognised that lice can and do give rise to such conditions as impetigo and ecthyma, considerable credit is due to these authors for, firstly, showing that in the Army *Pediculus corporis* frequently deposits its ova on the pubic hair, thus defeating such antiparasitic measures as are directed only to the clothing and blankets; and, secondly, for showing that the lesions, and still more the distribution of the lesions, are sufficiently characteristic to enable a diagnosis of pediculosis to be made, even in the absence of live parasites or ova.

The object of this brief communication is to show that the contentions of Semon and Barber are entirely borne out by the experience of another base hospital.

In the last 4430 cases which passed through my hands there were 1074 of scabies and 1120 of pediculosis, the latter in every case carrying live pediculi or ova. There were in addition 919 cases of pyodermia (ecthyma, &c.) in which the distribution of the lesions strongly suggested pediculosis, but in which no absolute evidence was found. (As a majority of my patients come via C.C.S. it is not unreasonable to assume that for every case arriving with live parasites there is at least one who has been freed from them.)

A further point of some interest emerges. In this series of 4430 patients there occurred 152 cases of "trench fever." No case in which any cause—such, for example, as tonsillitis—for the pyrexia could be discovered was included, and all the 152 cases showed the symptoms which are recognised as characteristic of "trench fever." 143 of these occurred in patients suffering either from scabies or pediculosis, an incidence of 4·6 per cent.; while 9 only occurred among all the other patients, an incidence of 0·67 per cent. It would be unwise to draw deductions from so few cases, but the above figures certainly lend some support to the theory that trench fever is carried by lice.

Conclusions.—1. In the B.E.F. it is not exceptional for *Pediculus corporis* to lay its eggs on the pubic (and occasionally axillary and peri-anal) hair, thus defeating the antiparasitic measures in ordinary use. 2. Patients frequently reach the base with marked pediculosis, even after weeks' residence in C.C.S. 3. Pediculosis is almost certainly as serious a cause of disabling skin disease as scabies. 4. There is some evidence that lice are the carriers of the infection of "trench fever."[2]

I am indebted to Lieutenant-Colonel M. M. Rattray, D.S.O., R.A.M.C., for permission to publish these notes.

A CASE OF ACUTE ENCEPHALITIS.

BY W. B. RUSSELL, M.B. CAMB.,
MEDICAL OFFICER AND LIEUTENANT (T.), 2ND VOLUNTEER BATTALION, R.W.F.

THE following case seems of sufficient interest to record in THE LANCET.

On Thursday, June 27th, I was called in to see a woman, aged 29, apparently suffering from influenza, which began three or four days before, with vomiting, diarrhœa, pains in back, sweating and insomnia. I found her suffering from pain behind right scapula; T. 104°; no headache. The next day she was better, but had tendency to retention of urine.

On Sunday (June 30th) she was much worse, with furious delirium. She tried to jump out of the window, and smashed a big hole in window-pane with head. She refused food and drink, and had no sleep, requiring constant attention to prevent her escape. Next day she was quieter and took food and drink freely, but was still without sleep.

The following day difficulty in swallowing was noticed, and liquid escaped from a corner of her mouth. A day or two later she developed third nerve paralysis, with squint and complete inability to swallow. Attempts to administer drink led to convulsions, cyanosis, and partial suffocation, as in hydrophobia. Her limbs were rigid, but not so the jaw muscles; otherwise the case resembled tetanus, as the slightest touch or shaking of the bed provoked general convulsions. She rapidly grew worse, T. rose to 105·7°, and she died on July 5th. There was urinary incontinence.

Dr. A. N. Leeming, who saw the case, detected friction and signs of congestion of right lung, but sputum was not rusty. There was a cough and profuse herpes on lips and nostrils. He performed spinal puncture after death, and drew off clear c.s. fluid which contained no meningococci.

Dr. Leeming agrees with me in considering this to have been a case of epidemic meningo-encephalitis. There was no lethargy until near the end.

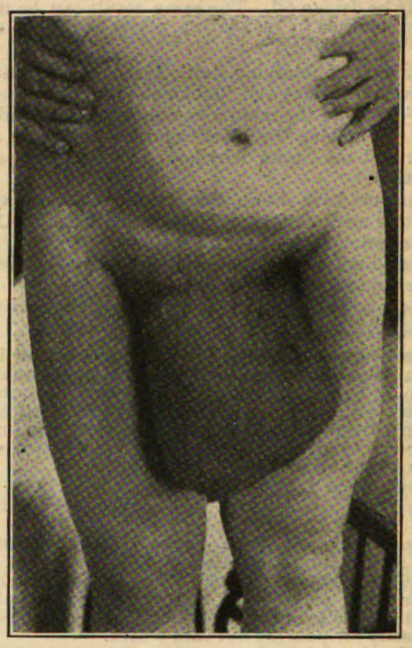
Colwyn Bay.

RADICAL CURE OF A VERY LARGE HERNIA.

BY J. ARTHUR BROWNE, B.A., M.B., B.CH.R.U.I.,
SURGEON, SAFFRON WALDEN HOSPITAL.

THE unusual size of this right oblique inguino-scrotal hernia would seem to justify a note thereon. It was larger than the patient's head and made one think of elephantiasis scroti. The penis had completely disappeared, and the urine issued through a channel resembling a deeply-sunk navel.

The patient, aged 28, very stout, first noticed his rupture three years previously. Had suffered little inconvenience; able to drive van. I performed a radical cure by Bassini's method, but without transplanting the cord. The opening of the canal admitted three fingers with difficulty. Sac was very thick and voluminous, with numerous large and



Condition before operation.

tortuous veins; and contained two feet of ascending colon, the cæcum and appendix, and six feet of ileum with mesenteries. It required considerable patience to restore contents to abdomen.

Owing to thickness of sac and firm adhesions to scrotal tissues, I thought it well to divide it across and leave the distal end *in situ*, separating larger proximal portion and cutting it away after tying neck with thick silk high up in inguinal canal. There was some orchitis thereafter, which subsided in a few days, and part of distal end of sac sloughed, causing slight suppuration in lower end of operation wound. Otherwise recovery was uneventful.

Newport, Essex.

[2] The above was written before direct evidence on this point had been obtained by the Commission on Trench Fever. The figures have since been brought up to date (May 4th, 1918).

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

The Prevention and Arrest of Lice-borne Diseases.

A MEETING of this society was held on July 17th, Sir RICKMAN GODLEE, the President, being in rhe chair, when Colonel WILLIAM HUNTER, C.B., A.M.S., gave a lecture on the Prevention and Arrest of Lice-borne Diseases (Typhus, Relapsing, and Trench Fevers) by New Methods of Disinfection. The speaker laid special stress on the importance of trench fever. Of the medical sick in the Eastern Command 10 per cent. were cases of trench fever and about another 10 to 14 per cent. came from those admitted for P.U.O. Any method of disinfection must be available at all times and must be easily devised and worked. The lecturer then gave a description of two forms of disinfection which he had used on an extensive scale in Serbia, in Egypt, and in Salonika. The first was barrel disinfection, a method devised by Lieutenant-Colonel G. E. Stammers, which was very effective and very cheap. For this an ordinary wine barrel was needed (or a sanitary dustbin). One large and four or five smaller holes are bored in the bottom, and the barrel is placed on an iron boiler containing water which is heated from a fire trench, the barrel being separated a few inches from the boiler by rings or bricks. The lid is kept on tightly by a stone placed on top. The clothes are placed inside. The barrel heats in about half an hour to 100° C., and disinfection is complete an hour later. The principle on which disinfection is carried out is the destructive effect on protoplasm of steam in motion. Three barrels could be heated over one fire-trench, but if this were done it was impossible to guarantee eqnal and efficient heating power in all three barrels. Four barrels should be sufficient for a regiment, and clothes should be disinfected every three weeks. For disinfection on a large scale (i.e., masses of troops) within a short space of time he used the railway van disinfector. This was devised also by Lieutenant-Colonel Stammers, and modified by himself. For this method modified ordinary luggage vans are used. Steam from the engine is discharged backwards into the vans by means of pipes running along them longitudinally. The clothes are either hung on hooks or across bars, or done up into bundles and placed on shelves all round the van. When the doors are shut the steam is turned on. At first water is seen to drip from underneath the door, and at this time the clothes are wet. At the end of half an hour disinfection is complete, there is no drip from around the door, and the clothes are only very slightly damp, becoming quite dry about half to one minute after being shaken out. Railway van disinfection had been used extensively in Egypt, and by this method the complete kit of 8000 men could be disinfected in four days, or 18,000 in ten days. He had made tests by placing various articles inside the van. Eggs were boiled hard in 10–15 minutes, potatoes became floury, cultures were sterilised, and a thermometer packed in the centre of a large bundle of clothing registered 105° C. The initial cost of the van disinfector was £50–£60, that of the barrel disinfector a few shillings. Photographs were exhibited showing the actual disinfection of 500 Turkish prisoners, and charts were displayed illustrating the remarkable checking of the incidence of relapsing and typhus fevers in Serbia and the lowering in the mortality rate. He considered that disinfection could be carried out by these practical measures more effectively and expeditiously and more cheaply than by any other form of disinfector at present in use.

In answer to various questions put to him by members present, Colonel HUNTER said that steam in motion at any temperature over 70° C. destroyed protoplasm. No part of the scheme was devised to raise the pressure in the van, but the steam escaped from the boiler into the van at a pressure of 4–5 atmospheres. The heat of condensation and the pressure produced a temperature of 105° C. in 5–10 minutes. He had had no accidents with these disinfectors. During the time represented in the charts the conditions were of the worst description.

Reviews and Notices of Books.

I. *Diseases of the Heart.* With a Chapter on the Electrocardiograph. By FREDERICK W. PRICE, M.D. Edin. London: Henry Frowde and Hodder and Stoughton. 1918. Pp. 472. Price 21*s.* net.

II. *Clinical Disorders of the Heart-beat.* By THOMAS LEWIS, M.D. Lond. Fourth edition. London: Shaw and Sons. 1918. Pp. 120. Price 6*s.* net.

I. Dr. Frederick Price adds a comprehensive work on an important subject to the practitioner's library. It may seem that in this particular branch of medicine there is nothing further to say for the moment. But Dr. Price does not aim at new contributions to his subject. By great care, and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observation. Matters of merely theoretical interest have been omitted, leaving room for the essentially practical points needed by the practitioner. The author's presentation of the newer teaching on cardiac arrhythmia is lucid and not too prolix, and a large series of carefully selected curves assists greatly in the elucidation of this difficult subject. In these chapters the work of Mackenzie, Cushny, Wenkebach, Lewis, to say nothing of the author's own valuable researches, has been admirably dealt with, and the reader may feel assured that he is getting the composite results of all these investigators rather than the view-point of one observer only. We are greatly impressed by the care shown in the arrangement of the subject-matter and by the literary exactness of the text. If we picked chapters for special commendation, we should specify those on Heart Failure: its Symptomatology, Auricular Fibrillation, Auricular Flutter (which has already appeared in these column), Carditis in Childhood, and Angina Pectoris—Pseudo-angina. We are pleased to find a frank invitation to the practitioner to combine with his own clinical experience the results of the graphic method of investigation as yielded by the more easily managed instruments, such as the sphygmograph and the ink polygraph. The results of the electro-cardiograph are reserved for a special chapter at the end of the book.

We regret the brevity of the chapter on Functional Disorders of the Heart and the absence of any comparative account of the different clinical features observable in the course of the different forms of valvular disease. It is very helpful to the student, for example, to point out the very different symptoms that are apt to arise when a heart that is the subject of aortic incompetence slowly fails, and when the same organ fails after years of a well-established mitral incompetence. And again, the different manifestations of cardiac inadequacy in a case of mitral stenosis and a case of mitral regurgitation. These broad and more philosophical views are useful, and might have been expected in a work of this scope. We note a good account of "primary cardiac overstrain" ("heart strain" would surely be a sufficient and unequivocal term?), but we think it is somewhat spoilt by the long note supplementing the account, and referring to the discussion on this subject at the Royal Society of Medicine. The author's own ideas are here obviously subjugated to those of Mackenzie, and the artificial adherence accounts for the confusion occurring in the following sentences. "While there is much to be said for the theory that these cases are the result of toxic poisoning following some microbic invasion, the practical evidence is too vague for dogmatism. What the toxins may be, or how produced, does not, so far, invalidate the results of the treatment advocated by Mackenzie. The treatment is mainly based on the assumption that the root of the malady lies in the central nervous system, the cardiac symptoms being merely incidental." In the etiology of aortic incompetence we find no reference to syphilis, which we regard as second only in importance to rheumatic fever in this connexion. We do not agree with the author that mitral stenosis results from acute rheumatic endocarditis. But these are small matters. We repeat our praise of the clearness of presentation of the subject and

the practical scope of the work. The production of the book is admirable and deserves a word of praise on its own account.

II. The appearance of the fourth edition of Dr. Lewis's excellent handbook testifies to the growing interest in modern conceptions of cardiac arrhythmia, and the increasing desire on the part of the practitioner to understand the new terminology and to weave it into his everyday practice. This little book not only serves to lay the foundation of such knowledge, but there is very little of any practical consequence in the subject which the reader will not find in the brief compass of its pages. "The chief derangements of the rate and sequence of the pulse and heart-beat as they are felt, seen, or heard," are here briefly but adequately described. The several chapters deal with sinus arrhythmia, heart-block, extra-systoles, tachycardia, auricular flutter, auricular fibrillation, and pulsus alternans. Dr. Lewis reminds the reader that there are few important disorders of the heart-beat which the unaided and practised senses may not recognise. So long as that fact is continually emphasised we may have no fear that mere instrumental records will displace the far more important training of the eye and hand and ear. The function of instruments of precision is to supplement and confirm these, not to supplant them—a fact which Dr. Lewis does not fail to make abundantly clear. In discussing the differential diagnosis of paroxysmal tachycardia Dr. Lewis says that in his "judgment there is no sufficient evidence that a healthy heart is ever damaged by muscular exertion, however severe or prolonged." "Is it to be supposed," the author says, "that the organ is so ill-protected that it is to be damaged by actions natural to man?" But surely there is a fallacy here: "however severe or prolonged" may include very *unnatural* effort.

I. *The Basis of Symptoms: The Principles of Clinical Pathology.* By Dr. LUDOLPH KREHL. Translated by A. F. BEIFELD, M.D. Third American edition; seventh German edition. London and Philadelphia: J. B. Lippincott Co. Pp. 517. Price 21*s.* net.

II. *Symptoms and Their Interpretation.* By Sir JAMES MACKENZIE, M.D. Edin., F.R.S. Third edition. With 19 figures. London: Shaw and Sons. 1918. Pp. 318. Price 8*s.* 6*d.* net.

I. THE word pathology has been wrested from its original broad meaning during the past two decades, and has come to connote that section of etiology which has to do with laboratory investigation—morbid histology, morbid anatomy, and bacteriology. To the branch of medicine in which laboratory investigation and clinical examination are intimately associated—hæmatology, urology, &c.—the term "clinical pathology" has been applied. It is not in this sense, but in one which much more nearly approximates to the older meaning of the terms, that use is made in Dr. Krehl's volume, "The Basis of Symptoms." "Pathological physiology" expresses equally well the material of which this book is a careful and forbearing study. The work is, in effect, an attempt to explain how diseases arise rather than to unfold their several manifestations. Without giving way to ungoverned speculation the writer attempts "to foster a more definite leaning upon the biological sciences in general." The author's aim is summed up when he says that "he who will understand disease must see clearly the inter-relationship of all the organs—must consider the unit only in its bearing upon the ensemble." To a few readers this book will appear, especially at first, to leave so many facts unexplained that it hardly justifies itself. But fuller acquaintance will, they may be assured, abolish this idea. In any case it is all to the good to know exactly what we know and what we do not, and a definite benefit accrues from the exposure of those gaps in an exact knowledge to fill which must be the aim of every student imbued with the scientific spirit. The chapters deal respectively with the circulation, the blood, infection and immunity, respiration, digestion, nutrition, and metabolism, glycosuria, gout, constitutional diseases, fever, the secretion of urine, and nervous diseases. The general sections upon the heart are admirably lucid, and tend to broaden the oft-times contracted horizon of the practitioner. Those paragraphs dealing with the cardiac arrhythmias are of special interest. The author utters a useful warning against regarding our current ideas on this subject as being based upon more than a useful hypothesis. He is of opinion that nervous influences play an important rôle here, and are not sufficiently allowed for. Even in so-called heart-block he considers that cerebral changes play a part—witness its occurrence in some cases of cerebral arterio-sclerosis, in which there is a complete absence of disease of the heart muscle. In the chapter on infection and immunity (written with the collaboration of Dr. E. Levy) there is an illuminating synopsis of our knowledge of the phenomenon of anaphylaxis, with consideration of its many bearings, and the reasons for regarding infection itself as an attenuated and protracted form of the anaphylactic state (Friedberger). There is a full account of the known relations between the bacteria of the alimentary tract and disorders of digestion, including constipation, and we welcome a criticism of the ill-defined and much-abused application of the term auto-intoxication. There is a careful analysis of the mass of data relating to obesity and its pathological associates. Acidosis is dealt with in the light of modern research. The still vexed problems of gout and diabetes receive guarded handling, and the disappointment that awaits us at the end of both these chapters is born of a sense of the gaps in our knowledge rather than of the inadequacy of the author's guesses, concerning which he exercises laudable forbearance. In the discussion on fever there occurs the following paragraph *à propos* the question whether or not the elevation of temperature is directly beneficial to the infected organism: "In recent years there has been a tendency to apply the Darwinian theory to pathological processes in general, and to say, for example, that fever could never have survived throughout immeasurable time were it not inherited as a useful weapon in the struggle for existence. Yet we may question to what extent the Darwinian theory applies to pathological conditions, for it seems equally reasonable to regard fever as a blind reaction against an injury, possibly useful or possibly harmful. The question is not one that can be solved by such philosophical considerations, and the final answer must be based upon established facts, derived either from bedside observations or from animal experiments." This reflection forms a good example of the temperate manner in which the author approaches most theoretical questions arising in connexion with pathological processes. In conclusion, we strongly recommend this work to all readers who are not content merely to accumulate a mass of unassorted clinical facts, but who wish to understand "how disease arises out of health; to be a nature philosopher." The book is the most thoughtful and complete account of this aspect of medicine that we have seen.

II. We welcome the third edition of Sir James Mackenzie's "Symptoms and Their Interpretation," the appearance of which proves the value attaching to the original work, and incidentally it also proves the interest shown in the author's particular method of approaching the study of disease processes. This book demonstrates to what a high degree of precision careful clinical observations can attain; and also how highly suggestive are the many questions bearing on general pathology arising out of them. The chapters dealing with pain, the mechanism of its production, its radiation and its bearing upon diagnosis, would alone make the work an extremely useful book of reference. It is possible that the author relies on symptoms too largely in the study of medicine, asking them to carry more weight than is wise; risking, in this manner, both accuracy of diagnosis and therefore efficacy of treatment. That is largely a matter of opinion. If this book serves to show how much knowledge of disease may be gained by methodical study of subjective states, and how important are many symptoms that too often get the scantiest attention, it will have achieved valuable results. Too often the practitioner forfeits data of the utmost significance by neglecting to take stock of the patient's sensations. This book is written largely in order to prevent such an error. Granted the need for care in collating and in interpreting the sensations, Sir James Mackenzie shows how both of these desiderata can be attained. He points out how this line of study suggests subjects for further research in the direction of clinical investigation, with a useful warning against regarding "original research" as being covered by laboratory work or as being best undertaken by the raw youth at the primitive stage of his medical career. We should like to see this book in the hands of all thoughtful practitioners, and we can think of no more appropriate gift to the profession at the time of the author's retirement from active practice than the issue of this present edition.

Blood Pressure from the Clinical Standpoint. By FRANCIS ASHLEY FAUGHT, M.D., formerly Director of the Laboratory of Clinical Medicine at the Medico-Chirurgical College, Philadelphia. Second edition, thoroughly revised. Illustrated. London and Philadelphia: W. B. Saunders Company. Pp. 478. Price $3.25 net.

Blood Pressure: Its Clinical Applications. By G. W. NORRIS, M.D. Third edition. Philadelphia: Lea and Febiger. 1918. Price $3.50.

THESE two books on blood pressure have proved their acceptability by passing into second and third editions respectively. Both can be warmly recommended. Dr. Faught's book has already received notice in these columns. It is thoroughly practical in its outlook, clearly written, and adapted to the needs of the practitioner. As the author states in his preface, his aim has been to avoid unnecessary discussion and the introduction of theoretic and inconclusive data. This makes it all the more valuable to those who wish for a straightforward account of a subject that they fear has become so technical as to be of interest only to the few.

Dr. Norris's book deliberately deals with some disputed aspects more fully. His description of the various instruments used would alone make it of value. But we must admit that some of his theoretical discussions have interested us as much as anything in the book. Thus the chapter on the functional efficiency of the circulation as determinable by blood pressure estimation and allied tests is largely destructive criticism, but none the less helpful at a time when perhaps too much reliance may be placed upon such methods in estimating the capacity of a recruit's heart for military service. The chapters on arterial hypertension are suggestive and full of fresh ideas. We wish we could have received more information on vascular crises; the author's classification is useful, but on a subject so little understood we should have liked more of the illuminating discussion he has provided on some of the other topics he reviews.

Practical Organic and Bio-Chemistry. By R. H. A. PLIMMER, Reader in Physiological Chemistry, University of London. New and revised edition. London: Longmans, Green, and Co. 1918. Pp. 636. Price 18*s.*

THIS is a revised edition of Dr. Plimmer's admirable handbook for practical work in physiological chemistry, with the scope extended to include the botanical side also. Sections such as those on bile and nucleic acids have been enlarged, and minor additions appear throughout. The book, though intended mainly for medical students, and dealing very fully with such things as proteins and enzymes, may also be taken as a general course in practical bio-chemistry. Experiments suitable for a preliminary course are indicated by an asterisk. Both author and students are fortunate in the early appearance of a new edition, bringing the matter of a rapidly developing subject fully up to date.

JOURNALS.

Quarterly Journal of Experimental Physiology. Editors: E. A. SHARPEY-SCHAFER, W. D. HALLIBURTON, C. S. SHERRINGTON, E. H. STARLING, A. D. WALLER. Vol. XII., No. 1. London: Charles Griffin and Co. 1918. Pp. 1-95. Price 7*s.* 6*d.* net.—Capillary Phenomena Observed in Blood Cells: Thigmocytes, Phagocytosis, Amœboid Movement, Differential Adhesiveness of Corpuscles, Emigration of Leucocytes, by John Tait. After some prefatory remarks on Rhumbler's hypothesis that ingestion of particles by cells is a simple physical process, the author deals with his own observations on the three types of blood cells found in the crustacean Ligia: (1) the explosive corpuscles; (2) the hyaline, which do not explode but flow onward on a glass surface; and (3) granular thigmocytes. Thigmocytes are defined as cells which are unstable in contact with a non-greasy foreign matter. Mammalian platelets are thigmocytes. The mere spreading on glass cannot be taken as evidence of vital activity. Phagocytosis involves a relation among three separate factors—phagocyte, particle, and surrounding medium (plasma). As to the mechanism of amœboid movement, it is not in every case due to alterations of surface-tension, but only in some cases—viz., when the movement is associated with instability of the cell substance while in contact with a foreign body. The fully granular cells of crayfish and cockroach blood are instances of unstable amœboid blood. Blood cells are known to show selective adhesions or differential adhesiveness, and, in fact, there is a delicately balanced relation in respect to adhesiveness between individual blood cells and other objects with which they come in contact—a fact which serves to broaden the basis of the investigation of "agglutinins."—The Blood of *Astacus fluviatilis*: A Study in Crustacean Blood, with Special Reference to Coagulation and Phagocytosis, by John Tait and J. Donald Gunn.—Carbohydrate Metabolism in Relation to the Thyroid Gland. III. The Effects of Thyroidectomy in Rats on the Gaseous Metabolism, by W. Cramer and R. M'Call. In rats removal of the thyroids and parathyroids does not produce severe disturbance of metabolism. The curves of CO_2 output and O_2 intake and R.Q. do not differ essentially from those of a normal animal. The power of the body cells to oxidise carbohydrates is not impaired, and it is inferred that the carbohydrate metabolism in experimenial hyperthyroidism is not due to a direct stimulating effect of the thyroid hormone on the oxidation of carbohydrates.

The American Review of Tuberculosis. Baltimore: National Association for the Study and Prevention of Tuberculosis. Price 35 cents.—The issue for May is exceptionally well illustrated, but there are only two original contributions. The first, by Dr. W. S. Miller, is a study of the nerves and ganglia of the lung in a case of pulmonary tuberculosis. He concludes with three queries: (1) May not the increased activity of the glands be due to the irritation of the nerves and ganglia? (2) May not the irritating and productive cough in some cases of tuberculosis, and the dry hacking cough in other cases, be due to nerve irritation? (3) May not the nervous hyperæsthetic condition accompanied by very shallow breathing which is a frequent result of gas poisoning in the present war be due in some measure to irritation of this nervous apparatus of the lung? The author leaves the answers to these questions in the hands of the physiologists and clinicians, who may, perhaps, be tempted to suggest that the notes of interrogation are superfluous, and that the author has been unduly cautious and diffident in his conclusions. The second original contribution is by Dr. G. E. Bushnell, and is a long clinical lecture on the signs and their interpretation in advanced pulmonary tuberculosis. It is a well-worn subject, but the paper is well written and illuminated by the shrewd observations of a clinician.

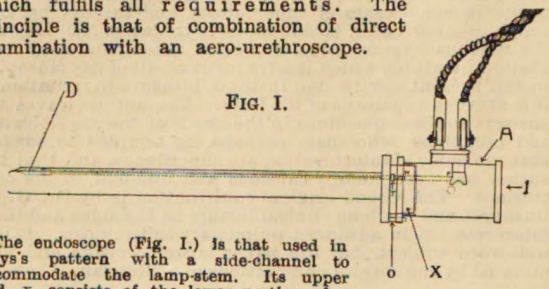
The Military Surgeon (Washington, D.C., U.S.A.).—In the June number there is a review of a paper issued by the Surgeon-General of the U.S. Army, quoting many foreign papers on the reconstruction and re-education of the disabled soldier—a task, as the reviewer states, that will require the most persevering patience and the sanest human sympathy. It is then considered whether these invalids are to be under civilian or medico-military control. The importance of enthusiasm for an ideal in the superintendent is obvious, also the benefit of judicious discipline for the patients during recovery. The editor observes that the military officer is promoted through his corps, until having proved his superior ability, study, and experience, and knowledge of his brothers-in-arms, he is selected to be a general officer; but has no knowledge of the medical profession sufficient to acquire its point of view. Therefore, the medical authorities of the Army, who have learned to work with the other branches, must be put in charge and given a staff sufficient in number and rank to take care of the disabled men in the most efficient and economical way. Particularly as they will be held responsible for the results, whoever has the organising of the scheme, while, in so far as they are hampered in their work, by so much the fittest of their patients will not completely recover.—Captain Wallace H. Pratt, of the Medical Reserve Corps, U.S. Army, before the war apparently a railway surgeon, makes valuable remarks on the prevention of pneumonia in camp, by diluting the infection with fresh air and decreasing it by attention to the mouth and fauces. His advice may thus be summarised: 1. Give the men enough blankets so they can endure the cold and neither lose their rest by being awakened by chill, nor be poisoned because they have been compelled to cut off their ventilation. 2. Do not give late leave; bring men home early so they can go to bed soon. 3. Keep the air of stove-heated tents moist. 4. Spray the men's noses daily once, gargle their throats twice, and make them clean their teeth four times. As for trains (his advice may be commended to officers R.A.M.C. in trains on the Continent) he notes that men moving by rail remain long without exercise in compartments often stuffy and overheated. He suggests that on the train men should be made to do physical drill in the corridors, while windows should be regularly opened; and that when the train stopped the men should be turned out of it and made to walk about. There is a very interesting note by Dr. Lloyd Garrison, assistant librarian of the Surgeon-General's Office, on a mistaken diagnosis of infectious disease in Paris about 1870, which prefaces an account, by Lieutenant N. R. Schiff, of a medical ward for acute cases, designed to avoid cross infection by means of screens made of sheets hung between the beds.

New Inventions.

A NEW AERO-URETHROSCOPE.

THE urethroscope, which up to the last three or four years was used only by the few specialists mostly in London and the large teaching centres in the provinces, has now come into general use owing to the establishment of venereal clinics, and medical officers in charge should be thoroughly acquainted with the appearance of the normal and abnormal urethra, if they are to treat chronic gonorrhœa successfully. For this reason I have thought it necessary to try to improve on existing patterns of urethroscope. There are two main types; the first, those through which the urethra is seen by direct illumination, and the second, those through which it is seen by indirect illumination or reflected light. By the use of the first type the urethra cannot be distended with air, but by the second type, of which Wyndham-Powell's aero-urethroscope is the best, all necessary instrumental work can be done with the urethra distended. I think, however, that the size and weight of the illuminating and operating mechanism are serious obstacles to its employment generally, and I venture to think that I have made an improvement which fulfils all requirements. The principle is that of combination of direct illumination with an aero-urethroscope.

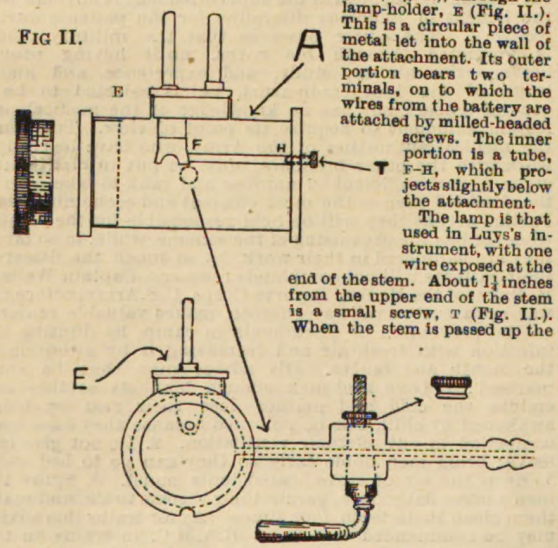
FIG. I.



The endoscope (Fig. I.) is that used in Luys's pattern with a side-channel to accommodate the lamp-stem. Its upper end, X, consists of the lower portion of a cone mounted on a flange in which is fixed an upright guide-pin, o.

The attachment, A, is a metal cylinder. Its lower end is a flange tapered internally to fit on to the cone, X. The upper end is made to receive either the examination cap, I, or the operating cap, C (Fig. III.). The examination cap is a lens of focal length corresponding to the length of the endoscope and is mounted in a metal rim, which fits into the attachment. The joint is air-tight, but loose enough to allow removal of the cap when the urethroscope is being used. Current is conveyed to the lamp, D (Fig. I.), through the lamp-holder, E (Fig. II.).

FIG II.



This is a circular piece of metal let into the wall of the attachment. Its outer portion bears two terminals, on to which the wires from the battery are attached by milled-headed screws. The inner portion is a tube, F–H, which projects slightly below the attachment.

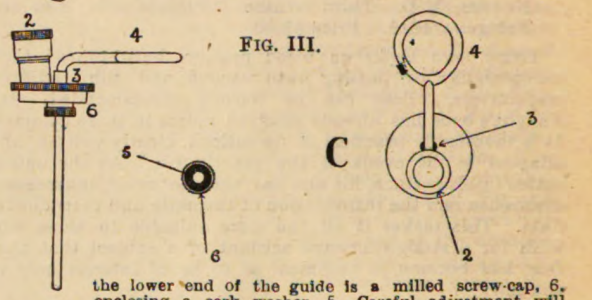
The lamp is that used in Luys's instrument, with one wire exposed at the end of the stem. About 1¼ inches from the upper end of the stem is a small screw, T (Fig. II.). When the stem is passed up the tube F–H the exposed wire makes contact in F, and the screw T engages in the lower end of F–H. Opening into the attachment at right angles to the lamp-holder is the tube with tap for attaching the bellows.

To use the instrument the lamp is screwed into its place, and the wires from the battery are connected up to the lamp-holder. If the light is satisfactory the rubber bellows are attached to the tube. When the endoscope is in position in the urethra and its interior has been carefully dried the attachment is fitted on to the cone, the lamp passing down the channel which just accommodates its widest diameter. To make the urethroscope air-tight gentle pressure of the endoscope is made upwards to the attachment.

The urethra is now inflated and examined; if no abnormality is discovered the examination comes to an end, but if there is need for operation the examination cap is removed and the operation cap is fitted in its place.

This is a metal disc perforated by two tubes. One (Fig. III., 2) is an eye-piece; the other is a guide, 3, with a bore equal to a No. 2 bougie English gauge, for the operating handle, 4, the lower end of which is tapped to receive a probe or knife. When the operation cap is in position the operating handle just clears the side of the endoscope. To give room for the movement of the handle the eye-piece is not placed in the centre of the disc, but a full view of the field is obtained by inclining it slightly from the vertical. The lens in the eye-piece is removable, so that when shorter endoscopes are used a lens of appropriate focal length can be fitted in. On the lower end of the guide is a milled screw-cap, 6, enclosing a cork washer, 5. Careful adjustment will compress the cork washer round the operating handle, to prevent leakage of air, and will allow easy up-and-down and slight lateral movement. It is advisable to lubricate the handle with a drop of lubafax. When the handle is not used the guide is closed with a small metal plug.

FIG. III.



The attachment is about 3 oz. in weight, and the whole urethroscope can be held easily in its place with the left hand gripping the urethra round the tube, leaving the right free to do the necessary manipulations.

The urethroscope has been made by Mr. Clive Wilson, Albert Road, Southsea, who has with much skill and ingenuity overcome many difficulties before a practical instrument could be turned out. The lamp-holder is entirely his idea, and the insulation is such that if the lenses are removed the whole instrument can be sterilised by boiling.

A. CAMBELL, M.B., Ch.B. Manch.,
Medical Officer, Portsmouth Venereal Clinic.

AN IMPROVED MON-AURAL STETHOSCOPE.

FOR some time past I have been using the mon-aural stethoscope which I have modified in such a manner as enables me to hear through it with both ears at the same time. The instrument has proved so satisfactory with me that I venture to bring it before the profession. It consists of an ordinary mon-aural stethoscope in two parts, to which is attached a piece of indiarubber tubing about 16 inches in length. This is connected at the ear-piece and communicates with the bore; at the free end of the rubber tubing is a comfortably fitting ear-piece. When in use the small free ear-piece is inserted into the ear farthest away from the examining side. The stethoscope is placed in position on the chest and used in the ordinary manner. There is no need to remove the tubing during the entire course of the examination and it in no way interferes with the replacing of the stethoscope into different positions. The advantages of this instrument over the ordinary mon-aural stethoscope are that both ears are engaged and the examiner can better concentrate his attention, since all extraneous sounds are prevented from reaching the otherwise unused ear and interfering with the examination. The sounds are louder, more clear, and distinct, owing to better coördination. For medical men doing work at the front or those returning whose hearing may have been affected by constant shell fire this instrument would be found a great help in examinations of the chest.

Messrs. Allen and Hanburys have kindly designed for me the pattern shown in the illustration.

LOUIS LOWENTHAL, M.D. Chicago,
Hampstead, N.W. M.R.C.S., L.R.C.P. Lond.

THE LANCET.

LONDON: SATURDAY, JULY 27, 1918.

The Fifth Year of War.

ANOTHER year of universal war will have commenced before our next issue, and it is right and proper that the profession of medicine should pause at this fifth milestone and look back on what the healing art has accomplished during the embittered struggle, in order to balance up the successes and failures of our organisation in the past and to see in what direction things should be better ordered for the future. At the outbreak of war the medical profession was admittedly unprepared for a struggle of such magnitude and duration, but this unpreparedness was shared with every section of the population, military or civil. With one great difference. The medical man had the distinction from all other civilians that as he stood, whether with or without a uniform, he was a trained man for medical needs, and therefore was of superlative value to the Navy and the Army. There is, of course, a medicine of peace and a medicine of war, but the medicine of war is a medicine of peace developed to suit the various exigencies of the case. The position of the medical man as the trained man for medical purposes was recognised in an honourable if embarrassing manner upon the outbreak of war, for an immediate draft was made upon our body of such magnitude and quality that when later a vast British army began to take shape and the war extended from continent to continent the supply of our own medical men available was already much depleted. It is old history now that when those who had the conduct of the war in their direct charge lacked the necessary imagination and foresight with regard to medical affairs, the situation was met by the medical profession instituting their own deliberative war committees. The Central Medical War Committee and other similar bodies showed themselves prepared to investigate the supply of medical men remaining in the various localities, and to meet the medical demands made by the Services, while keeping a watchful eye upon the due maintenance of the public sanitary and education organisations. What the Central Medical War Committee did for England and Wales the Scottish Medical Service Emergency Committee did for Scotland, and their task of recruiting the officers for medical military purposes, without imperilling civilian needs, has now become recognised as part of the official machinery and is still being worked out. In England and Wales the magnitude of the populations concerned presented a problem of considerable difficulty, but substantial help has been given by the Committee of Reference of the English Royal Colleges. This Committee discriminates with regard to the conflicting claims on the honorary staffs of the great hospitals and institutions, and the work of this Committee is still proceeding in the direction of a fair and economical distribution of medical care in the metropolis. The medical profession may congratulate itself upon the continuous and hard work done by these three bodies. Through their activities the medical profession, while remaining a civilian body, has organised itself for military purposes, and has done so with a spirit of unanimity, though the conditions of their employment were often hard to justify.

The fifth year of war opens with happy omen. The prolongation of the struggle with its terrors and griefs tends to produce among all the participants a frame of mind on which the actual happenings produce an immediate effect. The recent successes of the armies of the Allies on the Western front, and the presence of large and effective American forces in France, have shaken the martial ardour of the Central Empires. The reported words of the German Kaiser and of his principal military subordinates show that in Germany as well as in Austria the war is being prosecuted with less confidence in the invincibility of the German armies than heretofore, and that some apprehension is dawning of the reasons why the rest of the civilised world regard German actions and German professions with suspicion and anxiety. But with all this there is nothing to suggest an abatement in the relentlessness of the fighting, and the medical responsibilities remain undiminished. It is the duty of the medical profession to keep the Army and Navy properly equipped with medical assistance during the prolonged struggle. It falls to them also to organise the proper treatment of the sick and wounded on their return, while looking far ahead to the possibility of restoring to useful and happy citizenship many thousands of unfortunate men who have been damaged in the prolonged contest. As the war goes on, while the actual number of men engaged in fighting at any one time may not become larger, the toll of sick and wounded rises, and it is on the ever-increasing task of dealing wisely and efficiently with these unfortunates that we now have to focus our particular attention. In an admirable article which we publish this week Major-General Sir ROBERT JONES describes, as medical director of military orthopædics, the way in which orthopædic treatment is now being organised throughout the country, and it will be observed that under this amorphous heading a large part of the urgent work of military surgery has come to be included. Similar organised endeavours to deal with the results of tuberculosis, of shell shock, of ophthalmic and of jaw injuries (to mention only a few of a long category) have been set in motion, and it remains for the medical profession to justify by their methods of dealing with these sad cases the eulogy which they have earned in other directions.

The field of work is so immense and so laborious that there is room at times for discouragement, or for a lowering of the standard to the dead level of mere routine. But one thing should ever be borne in mind, and it is a wonderfully heartening reflexion. Just as the medicine of peace became the medicine of war, so the medicine of war need

not be scrapped, but will become again the medicine of peace. No iota of the work done or genius expended need be wasted. When the swords have been beaten into reaping-hooks and the tanks are drawing ploughs the hygienic and surgical achievements of the present war will remain as the birthright of a new generation. We have already seen how the service of hospital ships on the Tigris, which ply past the gate of the Garden of Eden, will remain as the civilising means of intercourse in a new Mesopotamia, from which water-carried disease will have been excluded by the clean water installations now dotted along the river banks. We have also seen how the effective adaptation of simple means to ends in the hygiene of the battle-front may revolutionise the practice of sanitation in our rural areas at home. It is equally true that the war-time discovery of how to restore the mutilated face by the combined art of sculptor and surgeon will benefit the peaceful victims of lupus, rodent ulcer, and accidental burns. The solution of the problem of the tuberculous soldier, whether in colonies or by the aid of all that is implied in the term after-care, must help to solve the ever-present difficulty of dealing with consumption in our great cities on lines befitting the twentieth century. Intensive study and team-work developed under the stimulus of war conditions will remain to fertilise the medical practice of peace. Medicine has this vast consolation of a fruitful continuity.

Combating Louse-transmitted Diseases.

THE recent demonstration that *Pediculus humanus corporis* transmits trench fever[1] is leading to more active steps being taken to combat lousiness among soldiers, because even the most obstinate combatant officer appreciates the loss in man-power that may be induced. The knowledge of the discomfort and injury produced by lice, and that these insects convey relapsing fever, typhus, and various skin affections, and possibly plague, has not resulted hitherto in adequate measures being taken to mitigate the evil. The biology of lice is at last receiving the attention which it deserves, and with a real knowledge of their life-history we shall be in a much better position to devise effective measures against their attacks. This does not imply that the requisite measures can be carried out in practice immediately, but it does mean that future work against lice infestation will be better directed.

In the meantime there is much that might be done which is not done. To check the spread of disease by lice it is necessary to keep soldiers clean. That is not a new discovery, but it is knowledge that has hitherto been turned to little account. To keep men free from lice it is imperative that their clothing and persons should be periodically disinfested. Half measures in this respect are of little or no use; indeed, they are dangerous because they give a false sense of security. Although lice may be spread in a variety of ways, infestation occurs mainly through contact and close association with verminous persons. Therefore strict attention is required to keep clean persons apart from infested individuals. The latter may carry lice or nits on any article of their clothing and upon their body-hair. When disinfestation is limited to cleansing a man's shirt it is bound to fail as a preventive measure, for the shirt, replaced upon the man, is promptly reinfested by the lice that wander again upon it from the other untreated clothing; moreover, if all the clothing belonging to a man is disinfested and his body-hair is not rid of nits or stray lice, he will reinfest his clean clothing. These are no new discoveries, but, again, it is knowledge that has not been made use of. The apparel and person of the soldier require attention whenever the military circumstances permit. As a matter of routine, weekly inspection of men by competent examiners is imperative if lousiness is to be avoided. To be effective the plan of procedure and treatment should be systematised and rigidly carried out. For the destruction on a large scale of lice in clothing and blankets the only remedies that can be thoroughly recommended are dry or moist heat. Lice and their nits are destroyed by 65°–70° C. in one minute. A most effective method of applying dry heat is by the use of huts in which the articles are exposed to air heated by means of coke braziers (Orr's huts) or by stoves. Smaller huts may serve as steam chambers, steam being led into them from a suitable boiler. Railway vans, stationed at sidings, have been used as steam disinfectors in Germany, Serbia, and Egypt on an extensive scale. Colonel WILLIAM HUNTER, in a lecture before the Royal Society of Medicine, which we report elsewhere (p. 107), describes the successful application in the early days of the Near Eastern campaign of disinfestation by means of barrels and railway vans; the plan was devised by his colleague, Lieut.-Colonel G. H. STAMMERS. Underclothes and other suitable effects may be disinfested by dipping them in hot water or immersing them in such insecticide solutions as petroleum, cresol, or lysol, with or without the addition of soap. Sulphur dioxide is an untrustworthy agent here; as the gas is injurious to uniforms, while it is slow in action and unduly costly, its use should be discontinued where better means of louse destruction are available.

Other means of combating lice are merely palliative; they do not effect the complete destruction of vermin. This must not be taken as meaning that palliative measures are valueless, they serve to keep down the louse population and may have to be relied upon at certain seasons when the systematic procedure detailed above cannot be put in action. Chief among palliative measures at present employed may be reckoned the application at frequent intervals of insecticides to clothing. The use of insecticides is a confession that men are not being kept clean by direct means, and may sometimes mean that nothing worth doing is being done. The indiscriminate use of empirical

[1] See McNee and Renshaw (1916), Brit. Med. Jour., i., p. 225; Journ. R.A.M.C., xxvi., p. 490; Davies and Weldon (February, 1917), THE LANCET, i., p. 185; Strong and Others (March, 1918), Med. Bull. (American Red Cross Soc. in France), i., p. 376; Byam and Others (May, 1918), Trans. Soc. Trop. Med. and Hyg. (In press.) The last two publications are specially important in relation to trench fever.

remedies is strongly to be deprecated, for many of those advertised are entirely useless. It is important that medical and sanitary officers should receive instruction in the best methods of dealing with lousiness in troops, for the matter is by no means so simple as it may appear to the uninitiated. In this connexion we would refer those interested to the papers by Professor G. H. F. NUTTALL, where the subject is exhaustively treated and illustrated.[2] The National League for Health, Maternity, and Child Welfare has recently issued leaflets and posters dealing with the problem of vermin in general (flies, lice, bugs, fleas), with the object of spreading a knowledge of their misdeeds among the public. The movement is laudable, but we wish that the league had obtained its "best scientific information" from more competent sources before spreading its leaflets broadcast.

Annotations.

"Ne quid nimis."

THE SUPPLY OF MEDICAL STUDENTS.

WE have received from the General Medical Council the following tabular statement giving the number of students in actual attendance on courses of instruction in preparation for medical degrees or diplomas. The statement refers to the month of May of the present year.

Topical distribution.	First year. Due to qualify in 1923.			Second year. Due to qualify in 1922.			Third year. Due to qualify in 1921.			Fourth year. Due to qualify in 1920.			Fifth year. Due to qualify in 1919.

* Including London.

The totals for the several areas in the order given are 1855, 3259, 2485, and 1886, with a grand total of 7630, of whom 5380 are men and 2250 are women. The high proportion of women students in the London area is noteworthy, especially in comparison with the Irish figures. It also appears from a subsequent part of the tabular statement not here reproduced that 671 of the men students are under 18 years of age and that 553 come from places outside the United Kingdom. It is instructive to compare the grand total of students in May, 1918, with the corresponding figures for the last two years.

Total Medical Students in Attendance.

May, 1916	6103	October, 1917 ...	7048
January, 1917 ...	6682	May, 1918	7630

This numerical comparison bears out Sir Donald MacAlister's statement at the recent session of the General Medical Council that the student registrations in 1917 exceeded those for any year since 1891. Although there is for the time being a "shortage of doctors," there is apparently no shortage of potential doctors.

THE CHOLERA SITUATION IN EUROPE.

FOR some time during the present year it has been known that cholera was appearing in certain parts of Russia, more especially in the city and district of Petrograd; at various places in the government of Podolia, in the west of Russia; at the town of Penza, in Middle Russia, 330 miles south-east of Moscow; at the port of Tsaritzin, on the Lower Volga, in the province of Saratoff; and at the port of Astrachan, also on the Lower Volga, 47 miles from its discharge into the Caspian Sea. In Asiatic Russia cholera was also prevalent in May of the present year at Tashkent, the capital of Russian Turkistan. With the coming of the summer season the cholera prevalence began to assume epidemic proportions in several places, particularly in Petrograd, which in past years has often been devastated by the disease. On July 13th the *Times* published a message, which had been transmitted through the wireless stations of the Russian Government, addressed "to all the Councils of the Corn Provinces and to all railway officials," to the effect that cholera was increasing in Petrograd, and that daily hundreds of persons were falling victims to the disease, the situation being greatly accentuated by the serious scarcity of food. Three days later another message stated that every day 500 cases of cholera were occurring in Petrograd, and that the infection was spreading to other parts of Russia and to Finland. About the same time information reached this country that cholera was epidemic in the city of Saratoff, on the Volga, 500 miles south-east of Moscow, and that "thousands" of persons had already been attacked by the disease. On July 12th a steamship from Petrograd arrived at Stockholm with six of its crew suffering from cholera, and a few days later another ship arrived at the Swedish port of Gefle, on the Gulf of Bothnia, with cholera on board. On July 17th yet another ship from Russia reached Christiania with five cases of cholera among its passengers. We understand that the Scandinavian Governments are on the alert and are making strenuous efforts to prevent cholera from gaining a foothold in their several countries, and that the Finnish-German Government also is making similar efforts. Experience of previous cholera epidemics has shown that England has generally received its infection by way of one of the northern or north-western ports of Europe. The war, for the time, has closed our trade with Baltic ports, and this, in a measure, has lessened the present danger of cholera importation into this country from that quarter. The fact that cholera has already been carried by ships from Russia into various parts of Scandinavia is not without significance. There are other Russian ports, such as Archangel and Murman, which are still in communication with England by shipping, and the possibility of the introduction of cholera into our country by this route cannot be disregarded. It has generally been considered that when cholera infection is imported into England in the autumn months the danger of its spreading is not so grave as when it is brought to us in June or July. Formerly, if the importation of the infection coincided with a hot summer there was grave risk of a serious epidemic. In recent years, however, owing to the greatly improved sanitary condition of the country, the danger that cholera might gain a footing on our shores has been much reduced. Simon's well-known observation that "excrement-sodden earth, excrement-reeking air, excrement-tainted water, these are for us the causes of cholera," no longer seems to apply. But it is

otherwise in Russia, and particularly in Petrograd, where the Bolshevists have swept away the municipal sanitary administration and the responsible officials, without whose assistance no city can hope to keep itself free of filth and filth diseases such as cholera: this remark is, no doubt, true as regards many other cities and districts in unhappy Russia at the present moment. For that and other reasons it is extremely probable that we shall hear more of the ravages of cholera in Russia in the next two or three months.

THE REINSTATEMENT OF DR. JOHN HENDERSON BELL.

THE decision of the General Medical Council was, as we pointed out at the time, equivalent to a reinstatement of Dr. J. H. Bell in the esteem of his colleagues and of a larger public. The miscarriage of justice of which he was a victim has already been to this extent made good. What he has suffered he has suffered, and although we can do nothing more to compensate him for his suffering, we can at least help to remove the pecuniary burden which still rests upon him. We feel sure that the appeal by four of Dr. Bell's most distinguished colleagues, which appears in our correspondence columns, will not fall on deaf ears, and we commend it to the notice of all our readers. No single one of us is secure, as the signatories remind us, from a similar mishap.

THE NEED FOR STATUTORY MEDICAL ADVISORY COMMITTEES.

IN an open letter to the medical profession Mr. Sidney Webb, who has been invited by the Labour Party to stand for Parliament, representing the University of London, gives his views on the proper relation of medicine to the State. He is convinced of the importance of the medical profession, as a whole, obtaining a genuinely effective influence on the administration of the service which it renders to the community. The ideal relationship between the various parts of the medical profession as well as that between the profession and the State will not, in his opinion, be discovered unless Parliament can be induced to provide for a much more effective and continuous intervention than at present exists of the mass of medical opinion and medical counsel —meaning predominantly that of the general practitioner—alike in national and in local administration. Mr. Webb goes on to say:—

> This will not be achieved merely by getting medical practitioners appointed as assistant secretaries or heads of departments, or even as Ministers of Health. I see not much advantage, and some considerable drawbacks, in making good doctors into not particularly good bureaucrats. There must, of course, be qualified medical men, clinical as well as sanitary, wielding real powers of administration in all health departments, central and local. But what I should like to see, in addition, is some provision for the continuous, authoritative, and responsible influence, on policy and on administration, of the medical profession itself. It seems to me that the Ministry of Health ought to be provided with a statutory advisory committee composed, not of the medical bureaucracy inside the office, nor yet of the nominees of the Royal Colleges, but of the duly chosen representatives of the profession outside the Government service; that this advisory committee ought to have no executive power (because we do not want it to become itself part of the bureaucracy), but unlimited freedom to criticise and advise; that it should be entitled to give its opinion, not merely on matters affecting the pecuniary interests of doctors or their status in the community, but on anything, done or undone, affecting health or disease; and that it should be free, whenever it thinks fit, to present an authoritative report to Parliament, uncensored by any department of the Government.

Mr. Webb suggests a similar advisory committee of the local medical profession, on a smaller scale, attached to every town and county council in the country, with analogous powers of reporting, uncensored by the town clerk or the health committee, upon the doings of the local sanitary authority. Dr. Basil W. Martin tells us that in Leicester, which has long been to the fore with its Public Medical Service, such an advisory committee representing the medical profession, local public bodies, and voluntary health organisations, was agreed to last week. The mayor is to be chairman and a member of the medical profession vice-chairman of this committee, which is to have no executive powers but will consider, in a purely advisory capacity, matters relating to the health of the town. Similar committees have for long had a beneficent influence in several Alpine health resorts. The example of Leicester will be watched with interest by less adventurous towns.

THE OCCURRENCE OF SPIROCHÆTA EURYGYRATA IN MAN.

DURING the past quarter of a century the study of protozoology has received more and more attention from medical men distributed in the four corners of the earth. The microscope has revealed a number of varieties of lower animal life which readily make of man a habitat and breeding ground under suitable climatic conditions. The spirochætes have a special predilection for various portions of the human mucous membranes. We have received an interesting paper by Temporary Surgeon G. Marshall Findlay, R.N., entitled "Observations on the Occurrence of *Spirochæta Eurygyrata* in Man," but space only allows of our giving his conclusions. In THE LANCET of March 3rd, 1917, Dr. J. W. Scott Macfie showed that this spirochæte is universally present in man on the Gold Coast, but its geographical distribution is almost unknown. For this reason Surgeon Marshall Findlay decided to examine the stools of British sailors and local natives in Egypt and the Red Sea littoral. His researches confirm those of Macfie, and indicate the almost universal parasitisation of man by this spirochæte in the equatorial zones of Africa. In Lower Egypt *S. eurygyrata* is present in the intestinal canal of man in a very considerable number of cases. In Upper Egypt it is universally present. In Europeans there appears to exist some correlation between the existence of pyorrhœa alveolaris and the occurrence of the spirochæte in the intestine. An impure culture of the spirochæte can be obtained by incubating in sterile hydrocele fluid at 37° C. It has long been suggested that a granular form exists in the life-history of certain spirochætes parasitic in man, and the present investigations indicate that *S. eurygyrata* is no exception to this rule. Dried fæces, three and a half months old, which revealed no spirochætes under the microscope, when incubated at 37° C. in sterile hydrocele fluid yielded a growth of active spirochætes. This spirochæte does not appear to be harmful to man, can be readily cultivated in the human organism (as also in monkeys) by oral administration of capsules containing the spirochæte, and is curable by the administration of thymol.

THE house and library of the Royal Society of Medicine will be closed for cleaning from Thursday, August 1st, to Saturday, August 31st, inclusive. During that time, however, medical officers of the naval, military, and air services, including the medical corps of the Dominions and our Allies, will be admitted to the library between 10.30 A.M. and 6.30 P.M.

MILITARY ORTHOPÆDIC TREATMENT.

AT the beginning of the fifth year of war the notion of "team work" as applied to war-time injuries and diseases is taking more definite form. And in no department of military medicine and surgery is this more evident than in the important, if vaguely defined, sphere of military orthopædics. A recent official pronouncement has included all of the following conditions in this sphere of influence:—

Derangement and disabilities of joints, including ankylosis. Deformities and disabilities of feet, such as hallux rigidus and valgus, hammer toes, metatarsalgia, painful heels, flat and claw feet. Malunited and ununited fractures. All fractures of the femur. Cases of nerve lesion requiring operative treatment. Cases requiring tendon transplantation or special surgical appliances.

These cases are now sent direct, as far as space permits, to one of the military orthopædic centres which have been established in each military command in Great Britain. There are three such centres in the Scottish Command and we give this week some account of two—at Aberdeen and Glasgow—as the result of a personal visit. To the third—the Edinburgh War Hospital at Bangour, Midlothian—an important addition has just been made in the form of a building for hydrotherapy, massage, and electrical treatment on a large scale. The gift of the Edinburgh Red Cross Committee, this was formally handed over at the end of last month by Lord Mackenzie to Lieutenant-Colonel John Keay, R.A.M.C., commanding the hospital.

The following address on the scope and aims of military orthopædic surgery was delivered by Major-General Sir Robert Jones at the recent Inter-Allied Conference on the After-care of Disabled Men, and deals with the whole extensive subject in an illuminating way.

MILITARY ORTHOPÆDIC SURGERY: ITS SCOPE AND AIMS.

BY SIR ROBERT JONES, C.B., CH.M., D.SC., F.R.C.S.,
MAJOR-GENERAL, A.M.S.; INSPECTOR OF MILITARY ORTHOPÆDICS.

I HAVE been requested to state briefly the way in which we deal in this country with the group of cases classified under "Military Orthopædics."

Nature of Cases: Departments of an Orthopædic Centre.

Both at home and in America the definition practically covers the surgery of the extremities. The Army Council Instruction includes under the term "orthopædic" ankylosis of joints, deformities and disabilities of the feet, malunited and ununited fractures, injuries to the peripheral nerves, and conditions requiring the transplantation of tendons. This represents a very large proportion of the injuries of war, so that constant effort is being made to increase our accommodation, which is at present inadequate. We opened our first orthopædic hospital in Liverpool in 1915 with 250 beds, and now we have centres scattered over Great Britain and Ireland with well over 25,000 beds.

In organising an orthopædic centre we decide to have every department represented, and that these departments should be so related that while they interdigitated they should not overlap. Our experience of uncontrolled special departments led us to conclude that they were lacking in a sense of proportion, and that cases were being bathed, massaged, or electrified which required fundamentally different treatment. Unless these special departments are guided by men with an orthopædic training they might as well not exist. In one institution which we visited we found several men being massaged who should have had their torn nerves sutured. Others being electrified required preliminary tenotomies, while the subjects of arthritis were undergoing harmful movements in Zander machines. Again, attempts were being made to break down old septic joints which required the gentlest care. From all the evidence it was clear that special departments should be controlled by well-trained surgeons, and remain in association with orthopædic centres.

An orthopædic staff will consist of neurologists, operating surgeons and their assistants, and the chiefs of departments. Consultations are encouraged and take place between the chiefs of the various sections, and the powers and limitations of each department are soon appreciated. The co-operation between the departments is of the most friendly character, and the chief of massage is in constant touch with the chiefs of electrotherapy and curative workshops.

The departments for treatment consist of: (*a*) Curative workshops; (*b*) gymnasium; (*c*) massage; (*d*) electrical treatment; (*e*) baths.

Therapeutic Value of Work: Active and Passive Movements.

Perhaps the most interesting development is the curative workshops. Obviously a very large proportion of the inmates of an orthopædic centre are of chronic type. Many of them have passed through various hospitals, and have undergone several operations. Their moral fibre has been weakened by prolonged strain, and they have lived a life of painful indolence for many months. To such men occupation is essential to their recovery, and the curative workshop has been to them a priceless therapeutic boon. For the initiation and organisation of these workshops the nation is deeply indebted to King Manuel, assisted by the princely generosity of the British Red Cross.

These shops have a double curative value—the psychological and the mechanical. As soon as a derelict finds himself once again a productive agent he becomes transfigured. Hope replaces despair, and we find this mental reaction soon produces its physical changes. The power to order a man to work is practically never exercised, for we obtain our ends more effectively by persuasion and example. Work is therefore very popular, and is, in addition, accompanied by rewards and privileges.

The mechanical therapy is of two kinds—direct and indirect. A man with a stiff foot which he is disinclined to use may be given a job to do with his hands. In the interest which the work inspires he forgets to nurse his foot, which almost unconsciously, and often very rapidly, becomes again mobile. A knee-joint which could not bear the continued strain of working a treadle will perhaps improve in function quickly while the patient, forgetful of his injury, is working with a saw. This is the indirect method of attack.

The direct is invoked when we give a man with a stiff shoulder paperhanging or whitewashing in order to loosen it, or screw-driving to pronate or supinate his arm, or a plane to mobilise his wrist.

The governing principle in regard to curative work is founded on the well-grounded belief that active movements are of infinitely greater value than passive movements. Active movements by exercise in one of its various forms have a direct curative effect upon the muscular structure. Passive movements are sometimes essential in order to stretch or flex a joint in preparation for active exercise, but in war injuries movements must be supervised by an experienced mind.

Work in the gymnasium is rendered attractive by games carefully devised for definite objects. If these games are competitive they often prove most helpful to the functional element so often grafted upon the organic. Although associated regional types of disability are grouped in classes, we depend mostly upon individual attention. A good instructor has a hundred eyes, can detect and watch men with special disability, and he always knows the danger of over-exercise.

Massage and electrotherapy are governed by well-considered surgical principles both in regard to the types of graduated contractions induced in order to simulate normal psychological action and the maintenance of uninterrupted relaxation in paresed muscles. We lay it down as a fundamental principle that muscles must not be massaged while they are under tension. In drop-wrist not for one moment is a patient allowed to palmar flex his wrist, it must be kept dorsi-flexed while either being massaged or while undergoing electric treatment.

In all centres we have artists and modellers, and careful pictorial records are kept of the various types of deformities.

Instruction in Military Orthopædic Surgery.

Shepherd's Bush Military Orthopædic Hospital, London, is typical of some 15 similar centres situated in large industrial centres over Great Britain and Ireland. Around each of these centres is grouped a series of auxiliary hospitals supervised by the parent staff.

It is desired to make these institutions educational in order to disseminate orthopædic knowledge among men who will have to deal with after-war problems. Intensive

instruction is being given at Shepherd's Bush, Liverpool, and Leeds, and in three months a well-trained young surgeon will have thoroughly grasped the fundamental principles.

We have been immensely indebted to the United States, who, as soon as they entered the war, sent over my friend Major Goldthwait and 23 extremely well-trained orthopædic surgeons. This was a delightful gift for the duration of the war. In addition to these, we have placed at our disposal 50 American surgeons of junior rank, who can both help us in our work and at the same time undergo a training.

Even yet—such has been the demand upon our young men—we have very few Britishers undergoing training. This is most unfortunate. A young surgeon would be so much more useful and adaptable at the front if he had undergone an intensive training in the surgery of the extremities for three months.

For educational purposes congresses are held twice a year, when the staffs from all the hospitals meet to discuss and relate experiences; while every three months visits are arranged between centres geographically convenient in order that they may link up in efficiency.

The Work of the Centres: Restoration of Patients.

The operative work done in these centres consists largely in rectifying the deformities of war—arthrodesis of joints in good functional positions when they are ankylosed in bad ones; bone-grafting and other reconstructive measures for bony deficiencies and non-union; lengthening of shortened limbs and readjustment of malunited fractures; the fixation of flail joints in good functional position; and tendon transplantation for various conditions.

We have included injuries of the peripheral nerves in our orthopædic list because they often require pre-operative, operative, and post-operative treatment, and they were the type of case which at the beginning of the war were found to be neglected owing to pressure on beds. Such cases are most carefully examined by neurologists, who work in close conjunction with the surgeon. In this way the nerve cases are under admirable control, and we endeavour more and more to segregate the cases requiring suturing under the care of those men who do the work best. A feature of the neurological work is the success which has attended tendon transplantation in irreparable damage to the musculo-spiral and posterior interosseous nerve.

Distinguished general surgeons overlook the work of each of the centres.

There has been a very natural anxiety on the part of the War Office at the prolonged retention of men at the orthopædic centres, but when the other side of the picture is presented and it is realised that over 70 per cent. of the cases are returned to military life it is evident that the patient care devoted to them is justified. The orthopædic hospital is the only link which makes it possible for the Pensions Ministry to make a useful citizen of a disabled soldier. The regret we must all feel is that so many of the deformities which we have to rectify might be avoided were surgeons more generally instructed in mechanical principles.

More recently—to expedite the process of cure, to diminish the time of hospital treatment, and to prevent the formation of these chronic disabilities—steps have been taken to bring suitable cases from overseas to the orthopædic hospitals. They are labelled "orthopædic" and taken in convoys direct to the centres. The stay in hospital is in this way much diminished, as the facilities and equipment are such as to ensure that the best thing shall be done and at once.

Suggestions as to Preventive Methods.

Another useful method of improving treatment is that of instructional propaganda. Command depôts are visited monthly by orthopædic surgeons, and the doubtful cases are discussed in groups. Instructions or suggestions are sent to the various hospitals all over the country dealing with preventive methods. The following suggestions, drawn up by the consultants, may be useful as an idea of what is being done.

(*a*) *Gunshot injuries through joints, followed by suppuration, generally result in ankylosis.*—The position of greatest usefulness in such conditions are:—

Shoulder.—The arm should be kept abducted to about 50°. The elbow should be slightly in front of coronal plane of body, so that when it is at right angles, and the forearm supinated, the palm of the hand is towards the face. The arm is placed in this position, while the scapula retains its normal position of rest. The humerus being fixed to scapula at angle indicated, the arm can be lifted to a considerable height by scapular action.

The arm should not be kept more abducted than 50°, otherwise it may not be possible to bring it down to the side.

Under no circumstances should the joint be allowed to ankylose while the arm lies hanging down, for the functional result will be so bad as to necessitate an osteotomy later on to correct the adduction.

Elbow.—The position must always be influenced by the patient's calling, but in the majority of cases the best functional results are obtained when angle between humerus and forearm is a little greater than a right angle—about 110°. The forearm should be supinated so that that palm is directed slightly upwards. If both elbows are ankylosed one should be about 110° and the other 70°.

Wrist.—All injuries of wrist-joint should be treated with wrist slightly dorsi-flexed, with fingers spread well out (see paragraph (*e*) later). There should be no exception to this rule.

Hip-joint.—Ankylosis should be secured in position of slight abduction, the thigh extended and slightly rotated outwards.

Knee.—It should be fully extended, care being taken to avoid hyper-extension.

Ankle.—The foot should be kept at right angles to the leg, in a very slight varus position. A valgoid position of foot is to be specially avoided.

(*b*) *Gunshot injuries of joints followed by rapid healing.*—During the period of rest these joints should be kept in the same position as indicated above.

If there is no considerable damage to joint surfaces movement may be expected in many of these cases if ample time is given for recovery from inflammatory change. Any attempt at breaking-down under an anæsthetic is to be deprecated. Such joints require very careful handling.

The shoulder will serve as an instance. Without removing the shoulder abduction splints the joint should be well massaged for a few days. If there is no reaction it is safe to remove the arm a few degrees from the splint and let it down again. If this is not followed by reaction it may be repeated every day and the patient encouraged to lift it actively from the splint. When he can do this easily the splint can be bent a few degrees (adducted), so that further movements can be practised. Massage and electric stimulation of the deltoid are indicated. The principle is one of alternative attack and rest. If reaction occurs a further rest of the joint is needed.

A similar principle applies in injuries of other joints.

(*c*) *Injuries involving tissues in neighbourhood of joints, resulting in suppuration, deep scarring, &c.*—No attempt should be made to break down these cases under an anæsthetic.

The knee-joint will serve as an example. When by massage and other tests there is reason to expect no inflammatory reaction graduated movement may be attempted. The knee is straight, with, say, 10° of movement; a splint is moulded allowing the joint to flex to 25°. The limb is bandaged to the splint. When the joint has yielded, so that limb lies easily on splint, it should remain in that position for recovery of strained tissues to occur. Movements are then practised by patient within range of 25°. If voluntary movement is free within that range a greater angle is given to the splint and treatment is repeated. If the joint becomes tender and stiffens in the new position it must be placed back in straight position and rested. When movement has been secured to about 45° movements may be continued in the gymnasium.

In all extra-articular lesions of the axilla and its folds, where ankylosis of the joint is not expected, the arm should be placed in the fully abducted position.

(*d*) *Injuries occurring at distance from joints, fractures, &c., with inflammatory changes occurring in muscles.*—No joint, not the seat of an arthritis, should ever be allowed to stiffen permanently.

In all fracture cases where it is possible to move the joint without interfering with the fixation of the fragments this movement should be practised. One gentle movement in each direction once in two days is sufficient. Passive movements which involve frequent repetition of the same movement are unnecessary and often harmful.

If the joint is very stiff after prolonged immobilisation, and where the bone is supposed to have united, great care is required. The bones above and below the joint should be well splinted while movement is started if necessary under full anæsthesia. Unless the joint yields readily the surgeon should be content with a few degrees of movement, the joint should be secured for a few days, and the surgeon may renew his efforts from time to time. Bones are soft for many months after a gunshot injury, and many fractures have occurred again as the result of attempting to move the joint without first protecting the bone from strain. This is especially true of fractures above the knee and near the shoulder-joint.

(*e*) *Stiff fingers.*—All splints for dorsi-flexion of the wrist, especially where fractures or inflammatory changes have occurred in metacarpals and phalanges, should be moulded in the position the hand takes when holding a cricket-ball.

Particular care should be taken not to over-extend the metacarpophalangeal range, as stiffening in this position is most intractable. The palmar arch should be maintained concave, the short dorsi-flexion splint should leave ample room for movement in the metacarpophalangeal range, and should be moulded to allow of abduction of thumb. At earliest possible moment active movements should be encouraged, and massage and passive movements should be gently practised. The so-called breaking-down the fingers followed by swelling from effusion retards recovery. The movements should be very gentle to be effective.

General remarks.—In all cases where the injury does not directly involve the joint, massage and active movements should be encouraged.

Even when a joint has to be fixed in consequence of a fracture in the neighbourhood early massage and electric stimulation is needed in order to prevent adhesions forming in the muscle sheaths. The patient should also be taught how to contract his muscles while the limb is splinted.

Splints should not be applied to the fingers except where they are the actual seat of fracture or active inflammation.

In all fractures of the forearm the hand should be supinated.

All splints should be removed from the upper extremity at the earliest practicable moment. As bones take a very long time to harden, the lower limbs, inasmuch as they have to bear the body-weight, should be guarded against deformity during walking. Neglect of this precaution has given rise to many cases of bowing and overlapping of the femora.

All gunshot injuries of the joints have to be treated with great gentleness, and the breaking-down of such cases under an anæsthetic is to be generally avoided. Our pre-war experiences are not applicable to gunshot injuries.

All scars about joints should be kept extended during healing unless a contra-indication exists. Care should be taken to prevent equinus at the ankle taking place during the treatment of other lesions of the limb.

As patients have to be discharged while still under treatment, it is imperative that full instructions should be given to the local Pensions Committee as to further treatment.

These instructions give the various surgeons, many of whom have not had an orthopædic training, fundamental principles upon which they can act.

Artificial Limbs.

All the artificial limbs in the country were made first of all at Roehampton House in London. This hospital, though not included in the orthopædic scheme, is staffed by orthopædic surgeons. It was soon found necessary to decentralise, and limbless hospitals were started in Scotland, two in Ireland, and one in Wales. Quite recently it has been decided to start fresh centres in direct connexion with the orthopædic centres at Liverpool, Leeds, Manchester, and Birmingham. Three of these have already started work. They are under the joint control of the War Office and the Pensions Ministry. The patient remains in the Army until his limb is fitted.

But the curative workshops can be utilised in an invaluable way by the facility with which they can turn out *provisional limbs* of a cheap but effective pattern, by means of which the soldier can be provided with a method of locomotion as soon as he can bear his weight on the stump. He can very soon discard his crutches and move about with a stick.

A further boon has been conceded. He can go to his home on furlough with this provisional limb until such time as he is required to enter the "limbless" hospital for the adjustment of the permanent artificial leg.

Treatment and Training of Pensioners.

Such are the means adopted to restore function and render the patient fit to return to the Army or to go back to civil life. If sufficiently restored, the patient may go to a Command Depôt for further training, or be remitted direct to his unit and become again a serving soldier.

If he is so disabled as to be unfit for further service he is discharged from the Army and becomes a pensioner, coming under the supervision of the Pensions Ministry. The discharged soldier, now a pensioner, may be able to go back to his old trade, or he may find a new job in which he may be employed without further training; or he may be re-educated for another trade or craft. Arrangements are being made by means of classes in the technical schools, through private employers, or by the establishment of new institutions, in which he can get both training and treatment.

Many of the orthopædic pensioners require very prolonged treatment, necessitating close observation for a considerable time, combined with massage and electrical treatment, &c. For this purpose numerous out-patient clinics are required and set up. One paramount consideration should be kept steadily in view by the Ministry of Pensions in this connexion. Any provision for the treatment of the orthopædic pensioner must be made so as to allow supervision, control, and inspection by adequately trained surgeons. Continuity of treatment is lost otherwise, and the patient, careful work of months may be undone.

Organisation.—The complete organisation in relation to the treatment and training of the pensioner should include: 1. An out-patient clinic, with massage and electrical installation. 2. Beds for in-patients. Both these to be inspected and supervised by specially trained surgeons. 3. Hostels. 4. Means of re-education.

Military orthopædic centres exist now in all the commands.

In the Scottish Command there are three—at Aberdeen, Glasgow, and Edinburgh. At all three, and at Dundee as well, arrangements have been, or are being, made for the correlated treatment and training of the pensioner.

In the Irish Command there are two orthopædic centres—Belfast and Dublin.

In Wales the Welsh Metropolitan War Hospital, Whitchurch, near Cardiff, is the main orthopædic centre. A second one is in the process of being established at Newport, Mon. Arrangements are now being made at Cardiff to coördinate the treatment of the orthopædic pensioner with the military orthopædic centre at Whitchurch.

In England there are two orthopædic centres in the Northern Command—at Newcastle-on-Tyne and at Leeds. In both the pensioner is to be dealt with by association with the organisation of the military centres.

In the Western Command (in which Wales is included) there are in addition centres at Liverpool and Manchester.

In the Eastern Command a military orthopædic centre is being organised at the military hospital at Edmonton.

In the Southern Command centres exist at Birmingham, Netley, Oxford, Reading, and Bristol; and in the London area there are Shepherd's Bush and Tooting Military Orthopædic Hospitals.

For the orthopædic pensioner it is necessary that all schemes of treatment shall be closely allied to these military orthopædic hospitals, so as to be able to take advantage of the special equipment and departments which are found there. The pensions beds must be either at, or closely proximate to, the orthopædic centre, as it is impossible to reduplicate staffs.

Many more subordinate clinics are needed, however, in towns where recognised orthopædic centres do not exist. Such institutions should be affiliated to the nearest orthopædic centres in the several commands. As each command possesses at least one military orthopædic hospital, these subordinate clinics should be set up by the Ministry of Pensions after consultation with the War Office, and be periodically inspected by skilled orthopædic surgeons.

Such arrangements must be made if continuity of treatment is to be maintained and the pensioner is to be restored to health. The staffs for the pensioners' clinics should undergo an intensive training at an orthopædic centre.

Conclusion.

Such are the scope and aims of military orthopædic surgery. Arising out of principles adopted for the treatment of crippled children, it has expanded into a huge organisation of extreme military importance—first, with the object of receiving the serving soldier and sending him back to the fighting line; and secondly, to reconstruct and restore the functions of those so badly crippled as to be useless as fighting units, but who, if properly treated, may take their places as useful workers and efficient members of organised society.

The name "orthopædic" may be open to criticism as applied to war surgery, but it is not easily replaced. It is intended to cover a type of case which requires for its treatment a combination of specially equipped hospitals manned by well-trained operative surgeons of mechanical mind who will work in team and accord with heads of special departments. They must be loyally prepared to develop the work they are most fitted for to the complete exclusion of any other branch for which they have a liking, and they must all combine in an effort to make the institution they work in an abode of inspiration and contentment for the wounded. We have the teaching staffs represented in all these centres, but the more so-called general surgeons we can rope in the more effective will we become.

ORTHOPÆDIC CENTRES IN SCOTLAND FOR THE

THE ORTHOPÆDIC DEPARTMENT AT THE 1ST SCOTTISH GENERAL HOSPITAL, ABERDEEN.

1. Gardener patients at work in the grounds.

2. The splint shop.

3. The shoe-making shop.

4. Making trawl nets or nets for Sinclair fracture beds.

I. 1ST SCOTTISH GENERAL HOSPITAL, ABERDEEN.

THE special hospital block at Oldmill, of which Lieutenant-Colonel J. Smart, R.A.M.C., has kindly supplied us details, forms the nucleus of the orthopædic department for which 500 beds are set apart. Two large wards have been equipped with the necessary appliances for electrical and massage treatment. Five wooden huts, erected some three years ago for accommodation of hospital orderlies and now no longer required, have been fitted up as curative workshops, where at present is being carried on: Carpenter-work, boot-repairing, net-making, splint-making, wood-carving, leather-work, photography, and other handicrafts. A new hut ward for 50 patients, with nurses' room attached, has been erected on the east side of the special hospital, at a cost of about £800, at the expense of the Red Cross. The ward, connected by corridors with the main building, is electrically lighted and heated by a low-pressure hot-water installation. The orthopædic section is under the supervision and direction of Professor J. Marnoch.

Plans have been prepared and approved, and tenders obtained, for the erection of a large new block to the north of, and in direct communication with, the special hospital buildings, to be used for orthopædic bath treatment, with large gymnasium attached. It is proposed to erect also four additional huts as workshops adjoining the hospital. The estimated cost of the extension, £6000, is to be provided by the Scottish Branch of the British Red Cross Society.

An *electro-therapeutic department*, under the charge of Major J. R. Levack, R.A.M.C., has been installed in one of the wards of the special hospital which has been given over to orthopædic surgery. The apparatus used has been provided by the Red Cross and consists of galvanic switchboards and special faradic coils with metronome interruptors. Earthenware tubs for use as baths are used with both of these. A high-frequency apparatus is in constant use, particularly as modified for diathermy. Some of the faradic coils are supplied from small accumulators, while the remaining apparatus is supplied from the main current, either directly or by means of a transformer.

The methods of treatment include graduated faradic contractions, interrupted and continuous galvanism, ionisation, diathermy, high frequency, muscle testing. Many types of cases are treated, including peripheral nerve injuries and muscle wasting; functional cases—e.g., total paralysis of one limb, spasmodic closure of hand and permanently open hand, functional foot-drop, spasmodic inversion of foot. Electrical treatment also proves of benefit in the case of stiff joints, adherent scars and in cases requiring re-education of muscles, in trench feet and allied disorders.

Massage department.—Massage and carefully supervised exercises form an important item in the treatment of many orthopædic cases. The massage department occupies a ward similar to that of the electro-therapeutic department. It is provided with massage beds and apparatus designed for carrying out different beneficial exercises. There are also a number of electrical hand vibrators.

Some idea of the extent of the work may be gained from a summary of the number of treatments given over a period of three months (December, 1917, January, February, 1918):—

—	Massage.	Electrical.	Radiant heat.
Dec., 1917, 4 weeks	1818	1124	164
Jan., 1918, 5 ,, ...	2798	1585	271
Feb., ,, 4 ,, ...	2404	1419	145
—	7020	4128	580

In the *plaster department* four different classes of work are performed: (1) Fixation of limbs in plaster; (2) plaster records of limb before, during, and at conclusion of treatment; (3) casts for splints; (4) plaster splints.

TREATMENT OF DISABLED SOLDIERS AND SAILORS.

THE MANUAL CURATIVE WORKSHOPS AT THE SCOTTISH NATIONAL RED CROSS HOSPITAL, BELLAHOUSTON.

1. General view.

2. The splint shop.

3. The art metal shop.

4. Wood-carving shop.

II. THE SCOTTISH NATIONAL RED CROSS HOSPITAL, BELLAHOUSTON.

The Scottish National Red Cross Hospital at Bellahouston, Glasgow, of which Lieutenant-Colonel H. Chaffer, R.A.M.C., is in command, contains 1140 beds, of which 500 are reserved for orthopædic cases. Of these, 30 beds are allotted to orthopædic cases from overseas and 50 to pensioners. The orthopædic centre is under the direction and supervision of Prof. R. Kennedy, assisted by Capt. A. H. Edwards, R.A.M.C., Mr. W. Laird, Capt. G. Miller, R.A.M.C., and Lieut. Wynn, M.R.C., U.S.A., in the electrical and massage department. The centre includes an orthopædic building for baths, electricity, massage, and radiant heat, with an orthopædic operating theatre adjoining, and a special block of manual curative workshops, of which we give a series of illustrations.

These workshops provide facilities for such handicrafts as metal-work, fretwork, boot- and shoe-making, tailoring, joinering, cabinet-making, wood-carving, leather-work, art needle-work, and splint-making, and include a paint-shop and blacksmiths' shop. Exercise is prescribed by the surgeon in charge of the case, who follows the man to the workshops and watches his course of treatment there. By a happy fortuity the commanding officer of the hospital is also a trained engineer.

The *plan of treatment* is described by Sir George Beatson in an illustrated pamphlet issued by the Scottish Branch of the British Red Cross Society (86, St. Vincent-street, Glasgow). The physical remedies used in connexion with these cases may be grouped under the headings: (1) Hydrotherapy, in the form of the various baths; (2) mechanotherapy, in the form of massage, movement, physical exercises, and manual curative workshops; (3) electrotherapy, with electricity in its various modifications; (4) radiotherapy, with its hot-air and radiation baths.

Hydrotherapy is carried out mainly by the use of baths, general or local, and sedative or tonic in their action. The pool bath is circular and can be partaken of by 10 to 12 patients at a time; the water is at a moderately high temperature with a gentle motion, and immersion in it has a soothing and calming effect. Local sedative baths are represented by different shaped arm and leg baths. Both pool and other baths may be converted into tonic baths by employing water at a high temperature and in rapid motion by turbine action. The whirlpool bath prepares disabled parts for massage and for movements of the joints and muscles by manipulation.

Mechanotherapy is carried out first of all by massage, which may be manual, where the various manipulations are carried out by the hands of masseurs or masseuses, or it may be mechanical, where the effects are produced by mechanical apparatus of the Zander or other type, driven by hand or electricity. Movements and physical exercises are used in connexion with preserving, restoring, or improving the functions of joints. They strengthen the activity of muscles, and indirectly have an effect on the general health.

Electrotherapy is represented by the various forms of electricity—viz., galvanic, faradic, sinusoidal, and high-frequency—administered through different electrical appliances for the purpose of furthering local nutrition and stimulating nerves. For radiotherapy hot-air and radiation baths have been fitted up, the heat being furnished by electric lamps of varying colour, from which high temperatures can be obtained without damage to the tissues.

The manual curative workshops are not primarily intended for the occupational re-education of the wounded man, but have the object of hastening improvement and getting rid of the disablement following wounds, thus rendering the men better able for everyday work in life. At the same time no doubt the workshops help to bring out the aptitude of men for any special trade, and thus have a value in deciding the question of re-education.

THE CANADIAN MEDICAL WEEK IN HAMILTON, ONTARIO.

(FROM A SPECIAL CORRESPONDENT.)

THE combined meeting of the Ontario Medical Association, the Canadian Medical Association, the Canadian Public Health Association, the Ontario Health Officers' Association, and the Canadian Association for the Prevention of Tuberculosis, which was held in Hamilton, Ontario, from May 27th to June 1st, proved to be the largest medical gathering which has ever taken place in Canada. About 4000 medical practitioners registered their names. With slight exception all the meetings were held in the Royal Connaught Hotel, Hamilton. The Congress was opened on the morning of May 27th by the Duke of DEVONSHIRE, Governor-General of Canada. The first meeting was devoted to public health matters.

Venereal Disease.—Child Welfare.—Tuberculosis.

Lieutenant-Colonel J. W. S. MCCULLOUGH, head of the Ontario Board of Health, dealt with the control of venereal disease in relation to the drastic Act passed recently by the Legislature of Ontario.

A Child-Welfare Session was held, to which Dr. GRACE L. MEIGS, of Washington, D.C., contributed a paper dealing with the year's campaign inaugurated in the United States by the Children's Bureau in Coöperation with National, State, and Local Child-Welfare Committees of the Council of National Defence, with the object of saving the lives of 100,000 children.

The eighteenth annual meeting of the Canadian Association for the Prevention of Tuberculosis took place on May 29th. The report of Capt. G. D. PORTER, the secretary, discussed the social and public aspects of tuberculosis.

Capt. H. W. HILL, medical officer of health for London, Ontario, drew attention to the need of differentiating between the human and bovine forms of tuberculosis, advocating efficient pasteurisation of milk to exclude bovine tuberculosis. Open cases of tuberculosis were rare in children, and should not be allowed to commingle with each other or with closed cases. He did not accept the view that tuberculosis was almost invariably contracted in childhood, but thought that a large number of cases arose after the age of 16.

Problems of the Returned Soldier.

At the suggestion of Surgeon-General FOTHERINGHAM a symposium was held on some of the problems of the returned soldier. Four papers were read. The first, by Lieut.-Colonel COLIN RUSSELL, C.A.M.C., described psychogenetic conditions and their treatment. Their etiology was explained as the result of the conflict between the natural inherent instincts and the more lately acquired control of these instincts by the higher centres. Deficient control, either congenital (as in mental deficiency) or lack of proper training, as well as the natural exhaustion of the acquired control of the higher centres under prolonged strain, were held responsible. The defeat of the higher centres and the abolition of the critical activities rendered the patient open to suggestions that met the wishes of the conquering instinct. Stress was laid on the fact that shell shock cases practically disappeared from the French Army when the rule was made that soldiers suffering from it would not receive a pension. Colonel Russell advocated the establishment in Canada of special hospitals to deal with these cases.

Colonel J. H. CAMERON, of Toronto, gave an address on Orthopædics, with special reference to the history of this branch of surgery. He took occasion to criticise sharply the sentimental mollycoddling of the returned soldiers indulged in by well-meaning people.

Lieutenant-Colonel HADLEY WILLIAMS, C.A.M.C., read a paper on the surgical treatment of nerve injury, and Lieutenant-Colonel ROBERT WILSON discussed the place of physiotherapy in the treatment of the invalid soldier.

Prevention of War Neuroses.

In the Section of Medicine an interesting paper on the prevention of war neuroses was presented by Dr. THADDEUS H. AMES of New York, based on his personal experience at Montreal and Toronto, of soldiers suffering from shell shock, and on that of other medical men from the battle lines. Shell shock was, he held, preventable, proof being found in the fact that in some regiments the condition was unknown. Discipline alone did not suffice to prevent it; successful prevention largely rested with the junior and non-commissioned officers, who came into close contact with the rank and file, and were able to talk familiarly with the men. When a change in behaviour was noticed the officer should distract the man's mind by all means in his power. A sharp reprimand would sometimes bring about the desired reaction. Everything depended upon the officer, the object aimed at being to induce the man to unburden himself. The soldier continually in peril of his life was peculiarly open to suggestion. In war the primitive emotions were unleashed. Training was of great value in restraining these emotions, and especially that of fear. Soldiers should be taught that discipline was for the good of the State and that fear was a healthy reaction in face of danger and admitted by all except the insane man and the liar. In view of their powers of prevention if they chose to exert them, Dr. Ames went so far as to state that officers were responsible for neuroses in regiments.

Broncho-Pneumonia in Army Camps.

An important paper on the virulent type of pneumonia observed in Army camps was read by Dr. W. G. MACCALLUM, of Johns Hopkins University, Baltimore. This disease seemed likely to be the cause of a large amount of sickness and death. While numerous cases of lobar pneumonia had occurred, the most noteworthy was a type of broncho-pneumonia due to infection with a hæmolytic streptococcus. This was studied first at San Antonio, Texas, and more recently at Camp Dodge, Iowa, where an outbreak occurred among the coloured troops, spreading later to the white troops in an adjacent camp. Like the outbreak of pneumonia at the camp Zachary Taylor, described by Dr. L. H. Mayers and Dr. W. W. Hamburger in THE LANCET, it frequently gave rise to empyema, was extremely deadly, and spread with great rapidity. Streptococcal pneumonia appeared to arise spontaneously, although in some cases cold or scarlatina was an antecedent, and more frequently measles, which was very prevalent in the camps at the time. The prominent symptoms were sore-throat, swelling of the larynx, and alteration of the voice owing to deep ulceration of the vocal cords. The fluid which collected in the pleural cavity was slightly turbid, at first straw coloured, becoming later brown, and then purulent and thick. Relief was afforded by aspiration or by resection of ribs, followed by washing out with Dakin's fluid. Post mortem the lungs were found distended with air and containing hard peri-bronchial nodules as large as peas, resembling miliary tubercles. Aspiration was often difficult owing to the presence of adhesions. After evacuation of fluid thickening of the framework of the lungs often took place. The picture was one of interstitial broncho-pneumonia, the bronchial area being filled with polynuclear cells. Infection appeared to be conveyed by personal contact or mouth spray, and increased when men were huddled together in barracks. Disinfection had no effect in staying the spread of the disease, and Dr. MacCallum thought that in vaccination lay the chief hope of checking it.

Delivery of Addresses.

The Address in Medicine was given by Dr. LEWELLYS F. BARKER, of Johns Hopkins University, who discussed the significance of heart murmurs found in the examination of candidates for military service. Dr. Barker pointed out that by improved methods and standardisation a large proportion of these rejected men might be rendered fit for whole or part service. Murmurs produced outside the heart had no effect upon the man's capacity for military service.

Dr. ISAAC A. ABT, of Chicago, gave the Address in Pediatrics on asthma in childhood. Dr. JOSEPH D. LEE, of Chicago, gave the Address in Obstetrics, discussing methods and operations for reducing fœtal mortality, with special reference to the newer methods of Cæsarean section.

The Address in Surgery was given by Dr. CHAS. H. MAYO, of Rochester, Minn., and was devoted to a consideration of cancer.

The meeting was a conspicuous success throughout, and a word of praise is due to its organisers, and especially to the energetic secretary of the General Committee of Arrangements, Dr. J. H. Mullin, of Hamilton.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions and donations to the Fund have been received during the week ending July 22nd:—

	£	s.	d.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

DIETETICS.

Special Rations for Invalids.

THE position of invalids has been greatly improved under the national rationing system which came into force on July 14th owing to the further powers of issuing extra rations in suitable cases now granted to Food Control Committees. These include power to deal with an extended list of diseases for which extra rations of meat, butter or margarine may be required, and to make grants of sugar or of white flour for a limited time. Application is now always to be made to the Committee of the district in which the applicant lives, and not directly to the Ministry of Food. The extra rations, or white flour, when granted, can only be purchased by means of authorities issued by Food Control Committees, and may not be supplied by retailers on doctors' certificates without such authorities. Except in the case of white flour or of extra rations for expectant and nursing mothers application is to be made on Form N. 36, copies of which may be obtained from food offices. This form includes a certificate to be signed by the doctor in charge of the case, stating the disease from which the patient is suffering and specifying the minimum weekly amounts of the food in question required by the patient. In the case of an application on the ground of tuberculosis the Food Control Committee may inspect the official register of notifications.

Meat, Butter, and Margarine.—In the case of adults the following diseases have been granted special consideration, the quantities given being the maximum weekly quantities, inclusive of the ordinary ration, which can be allowed in any case:—

1. Active tuberculosis,[1] pulmonary or otherwise: Meat,[2] 2½ lb.; bacon, 1 lb.; butter,[3] 3 rations.[4]

2. Diabetes and glycosuria: Meat, 2½ lb.; bacon, 1 lb.; butter, 4 rations.

3. Exophthalmic goitre: *Either* meat, 2 lb.; bacon, 1 ration; and butter, 1 ration; *or* meat, 1 ration; bacon, 1 ration; and butter, 2 rations.

4. Pernicious anæmia: Meat, 2 lb.; bacon, 1 ration; butter, 1 ration.

5. Cancer[5]: *Either* meat, 2 lb.; bacon, 1 ration; and butter, 2 rations; *or* meat, 1 ration; bacon, 1 ration; and butter, 5 rations.

6. Senile dyspepsia: Meat, 2 lb.; bacon, 1 ration; butter, 1 ration.

7. Convalescence after severe illness, severe operation, or serious loss of blood (including childbirth in which the child does not survive): Meat, 2 lb.; bacon, 1 ration; butter, 2 rations.

(In the case of 7, the grant is for 4 weeks; in the case of 6, for an indefinite period; in the case of 1–5, for an indefinite period, subject to renewal every 4 weeks.)

In no case can extra meat be sanctioned for the purpose of obtaining beef-tea, applicants being advised to use meat extract with or without the addition of milk powder.

Where a patient not falling into any of the groups mentioned cannot take one of the rationed foods an interchange may be granted on the following basis, viz.: 1 meat coupon a week = 1 bacon coupon a week = 1 butter coupon a month. In the case of children under 2 years suffering from diarrhœa and wasting or marasmus, extra meat, not exceeding 2 lb. weekly, may be granted for making raw beef-juice, but only for a maximum of 4 weeks.

White Flour.—No ordinary disease is held to require bread made from white flour. Application for a grant is made to the Local Food Office on a special form not used for any other food, for a period of six weeks and for not more than 14 lb. in all, and may be granted in cases of active gastric or duodenal ulcer, where the patient is confined to bed or only newly convalescent, in cases of gastric carcinoma or senile dyspepsia, chronic diarrhœa, or intestinal ulceration. The term "senile dyspepsia" is used to describe the form of flatulent indigestion often associated in the aged with chronic bronchitis or cardiac weakness. In the case of gastric carcinoma or senile dyspepsia renewal may be granted by Committees without fresh medical certificates. All other applications for renewal must be made to the Invalids' Flour Subsection at the Ministry of Food. The medical certificate in regard to white flour is a searching document, stating in each case whether the patient has recently tried the regulation grade flour, and if so with what effect, whether the present bread has been found unsuitable, even when thoroughly toasted, and whether the certifier is satisfied that the supply of flour of lower percentage extraction is essential.

Sugar.—Extra rations may be granted for a period not exceeding four weeks where a patient is medically certified to be unable to take solid food on account of difficulty in swallowing or because his disease necessitates a slop diet. No grant of extra sugar may be made to anyone receiving an invalid's ration of meat, butter or margarine. The total sugar granted, including the ordinary ration, must not exceed 1 lb. per week, except in the case of a patient requiring to be fed by a tube. The concession is not intended to apply to artificially fed infants or to healthy children. The renewal of a grant has to receive confirmation by the Special Diseases Subsection of the Ministry of Food.

Milk.—It is desirable to recommend milk rather than extra allowances of meat or butter wherever this will meet the need of the patient. In accordance with the model priority scheme a ticket for priority in the supply of milk may be issued to any person holding a doctor's certificate that he is entitled on health grounds to a certain specified daily quantity of milk. Application for a priority ticket should be made for any invalid unable otherwise to obtain the quantity found medically desirable.

Extra Rations for Expectant and Nursing Mothers.

We have already noted[6] the concessions made on behalf of maternity.

Expectant Mothers during the last three months of pregnancy may be granted: 1. An extra ration of the amount represented by either 2 meat coupons or 1 butter coupon per week. Application is made on a special form containing a certificate to be signed by a doctor or by a certified midwife. 2. A priority certificate for 1 pint of milk daily in districts where a milk priority scheme is in force.

Nursing Mothers will not themselves receive extra rations or priority milk tickets, but the following clauses apply to them: 1. The child's ration book will be issued on application, accompanied by a birth certificate. Where the registration of birth is unavoidably delayed an emergency card will be issued in the meantime, giving a weekly ration equal to the infant's ration, the application being countersigned by the doctor or midwife in charge. These provisions apply whether the mother is nursing the child or not. 2. In the event of stillbirth, or the death of the infant within one month, the mother may on a doctor's certificate be regarded

[1] The actual word "tuberculosis" should appear on the certificate.
[2] Implying here and elsewhere butcher's meat.
[3] Including butter and margarine.
[4] The ordinary ration, which may vary from time to time.
[5] If desirable some euphemism, such as "new growth" or "neoplasm," may be used on the certificate.
[6] THE LANCET, June 8th, 1918, p. 811.

as a convalescent. 3. In districts where a milk priority scheme is in force children under 18 months are entitled to a preferential allotment of milk up to 1½ pints daily, the mother using the child's allowance if she is nursing the child.

At *Maternity Feeding Centres* approved by the Local Government Board expectant and nursing mothers may receive meat up to 12 oz. per head weekly without producing coupons for it.

Rations in Other Special Cases.

In cases of grave emergency, where the doctor certifies that the life of the patient is in danger unless extra rations are granted, Committees are authorised to grant extra rations for one week up to a maximum (including the ordinary ration) of meat, 2 lb., and butter, 2 rations. Renewal of this grant must be confirmed by the Ministry of Food. No ordinary diseases, other than those already referred to, are recognised as grounds for the issue of extra rations. In exceptional cases of disease the Committee may forward an application to the Special Diseases Subsection of the Ministry of Food (29, Upper Grosvenor-street, W. 1) for consideration by their medical adviser. Applications so forwarded must be supported by strong medical certificates, grants being made only in exceptional cases. In dealing with importunate patients it may be borne in mind that the doctor has no power to grant extra rations, but only to recommend such a grant when convinced of its necessity, the final responsibility resting with the Ministry of Food.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

THE annual meeting of the Congress was held at Oxford on July 11th and 12th. As in former years, members enjoyed the hospitality of Keble College, while the gatherings were held in the Department of Human Anatomy.

On the first day Mr. SYDNEY STEPHENSON opened with an address on the History of the Congress, after which Sir WILLIAM J. COLLINS, Doyne Memorial Lecturer for the year, opened a discussion on Ophthalmology and the War, in which the following, amongst others, took part: Lieutenant-Colonel R. H. ELLIOT (London), Captain E. H. E. STACK, R.A.M.C., Miss MARION GILCHRIST (Glasgow), Dr. T. HARRISON BUTLER (Leamington), Captain P. H. ADAMS, R.A.M.C., Captain PERCIVAL J. HAY, R.A.M.C., Captain THOMSON HENDERSON, R.A.M.C., Mr. R. J. COULTER (Newport, Mon.), Major A. C. PURCHAS, N.Z.M.C., Staff-Surgeon R. J. E. HANSON, R.N.V.R., Captain T. H. WHITTINGTON, R.A.M.C., Mr. J. GRAY CLEGG (Manchester), Dr. GEORGE YOUNG (Colchester), and Mr. BERNARD CRIDLAND (Wolverhampton). Colonel ELLIOT concluded the proceedings by reading a paper on Some Useful Devices in Operative and Other Work.

On the second day of the Congress Sir WILLIAM BARRETT, F.R.S., read a paper, accompanied by demonstrations and slides, on Entoptic Vision, a subject which has recently fallen into neglect by ophthalmologists. Colonel HANFORD MCKEE, C.A.M.C., followed with a paper on Some Aspects of Military Ophthalmology, summarising the conclusions of a wide ophthalmic experience during the war. The morning session concluded with two papers by Captain HAY on, (*a*) Implantation of Cartilage after Excision or Evisceration of the Eye; (*b*) Vulcanite Casts as a Support for Protheses, both of which were illustrated by photographs of operative results and radiograms. In the afternoon cases were shown at the Eye Hospital by Captain ADAMS and Dr. A. W. ORR, after which Colonel ELLIOT read a paper on Herpes, and Dr. BUTLER one on Cataract Operations. In the scientific museum Sir WILLIAM BARRETT gave demonstrations with the entoptoscope. Captain HENDERSON showed sections of monkeys' eyes with special reference to Descemet's membrane, and Captain ADAMS described the histology of a hitherto unknown disease causing blindness in horses. Captain STACK exhibited a combined perimeter and scotometer. Mr. COULTER showed improved test-types. In the commercial museum various novelties were on view.

The contributions to the Congress will appear in the Transactions of the Ophthalmological Society of the United Kingdom, with which the Congress is now affiliated.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

METEOROLOGICAL OFFICE: ADVISORY COMMITTEE ON ATMOSPHERIC POLLUTION: SUMMARY OF REPORTS FOR THE MONTHS ENDING *Oct. 31st, 1917.* *Nov. 30th, 1917.*

Place.	Rainfall in millimetres.	Metric tons of deposit per square kilometre. Insoluble matter. Tar.	Carbonaceous other than tar	Ash.	Soluble matter. Loss on ignition.	Ash.	Total solids.	Included in soluble matter. Sulphate as (SO_3).	Chlorine (Cl).	Ammonia (NH_3).

THE CASE OF DR. JOHN HENDERSON BELL.

To the Editor of THE LANCET.

SIR,—On June 29th of last year Dr. John Henderson Bell was convicted of "attempting to produce a disease in a man belonging to H.M. Forces" and in the following week of "doing an act preparatory to producing a disease or infirmity" in another member of H.M. Forces, and on conviction was sentenced to six months' imprisonment with hard labour. The sentence on appeal was modified to imprisonment for the same term in the second division.

At the last meeting of the General Medical Council his case came before the Council, sitting to hear disciplinary charges against practitioners. The Council received evidence tendered at length by Dr. Bell and by counsel on his behalf, with the result that they did not see fit to erase his name from the Medical Register. The fact of conviction was accepted by the Council, reference being limited to the consideration whether or not the evidence justified removal of Dr. Bell's name from the Register. Dr. Bell in his statement described the treatment which he had administered in the two cases. In that treatment he appears to us to have followed a perfectly usual medical routine.

The first patient, a deserter who had stolen another man's papers, complained of a condition for which the treatment given would have been suitable. This man, who may have believed what he said, informed the military police that an operation had been performed upon him by Dr. Bell with a view to rendering him unfit to rejoin the Army. The second patient was an *agent provocateur* acting under the orders of the police, and such treatment as he received was the perfectly correct proceeding on the part of a medical man who was attempting to make a diagnosis. Dr. Bell's arrest was effected by a concealed police officer while he was in attendance on the *agent provocateur*. Not only did Dr. Bell treat the alleged conditions in accordance with the usual medical practice, but he received only the ordinary and modest fee from the first patient, an imposter who appears to have paid a sum of money to a third person in order to obtain medical treatment which would produce a disease. Dr. Bell did not receive that money, nor did the prosecution suggest that he had received it. No motive, therefore, for the imputed misdemeanour was alleged, while Dr. Bell's actions were in consonance with his entire innocence.

At the time of the conviction THE LANCET stated that there had been a miscarriage of justice. This miscarriage has been rectified to a certain extent—that is to say, Dr. Bell's name has not been removed from the Medical Register, a proceeding which follows automatically upon a criminal conviction. The decision of the General Medical Council not to erase his name from the professional roll was received not only by Dr. Bell's friends and patients, but also by the medical public, with profound approval. But, while his good name is thus restored to him, he remains under the weight of a substantial pecuniary burden. His misfortunes have cost Dr. Bell at least £800, and, despite the many claims upon the charity of medical men, we hope that a subscription may be raised at once to relieve him from this debt. There is not a medical man who may not find himself exposed to similar charges and victimised by similar proceedings.

We shall be very happy to receive subscriptions to a fund to reimburse Dr. Bell his expenses.

We are, Sir, your obedient servants,

DAVID FERRIER, WILLIAM OSLER,
G. LOVELL GULLAND, STCLAIR THOMSON.

July 22nd, 1918.

Subscriptions should be sent to Dr. Kinnier Wilson at 14, Harley-street, W. 1, and will be acknowledged in the columns of *The Lancet* and the *British Medical Journal*.

THE BACTERIOLOGY OF THE PREVAILING PANDEMIC.

To the Editor of THE LANCET.

SIR,—In your issue of July 13th Captains Little, Garofalo, and Williams write of their finding a small Gram-positive diplococcus as the predominating organism in the secretions of 20 cases from the prevailing pandemic, and of their inability to find *B. influenzæ* (Pfeiffer). As you state on p. 51 that this is the first serious contribution to its bacteriological study, it would seem of value to record contrary findings, few though they may be.

The expectorated sputum from a small group of typical cases was taken, as far as possible, early in the course of the disease. After washing the sputum in several changes of salt solution cultures were made on whole-blood agar and stained films prepared. In three-quarters of the number a typical small, watery, transparent, discrete colony was found in more or less profusion (in one case in almost pure culture). Films from these colonies gave a short, moderately slender, Gram-negative bacillus, tending to form groups, that was therefore considered to be *B. Pfeiffer*. The stained films also showed numerous rods of the same morphology as the cultures, although other rods and various cocci were present in all films, and in some cases numerous.

According to verbal report, investigations of other bacteriologists with the B.E.F. in France tend to support the view that the present pandemic is due to infection by Pfeiffer's bacillus, and therefore truly influenza. I quite agree, however, that the term influenza should be restricted to such cases and other names be given to epidemics due to streptococci (such as the recent Chicago outbreak investigated by Capps and Rosenow), diplococci, or other organisms.

I am, Sir, yours faithfully,

E. B. KRUMBHAAR, M.D., PH.D.,
16 (Phila., U S.) Gen. Hosp., B.E.F., Capt., M.R.C., U.S.A.
July 19th, 1918.

THE STERILISATION OF INFECTED WOUNDS.

To the Editor of THE LANCET.

SIR,—In the article by Colonel Sir Almroth Wright and his colleagues on the physiological sterilisation of infected wounds in THE LANCET of June 15th two facts are brought to light which must be regarded as of great importance in the future development of the treatment of gunshot wounds. These observers have shown: (1) that putrefactive organisms are destroyed by healthy serum alone; (2) that streptococci and staphylococci, while thriving in serum, are destroyed by leucocytes in the absence of excess of serum.

These important observations seem to establish a reasonable basis on which to build up the principles of treatment of wounds infected by these organisms. That caution is necessary, however, in the application of knowledge gained in the laboratory to conditions met with in the actual practice of surgery is shown by the fact that the conclusions drawn by Sir Almroth Wright from his experimental results, in so far as they refer to the closure of infected wounds, are far removed from those arrived at by clinical experience. Sir Almroth Wright states that wounds after early surgical cleansing and resection are "as good as sterile," and can be sutured with only the risk of an "occasional" failure if no dead spaces have been left. This is in general true, provided that the wound has not before operation been infected with virulent streptococci. But it is now commonly recognised by surgeons who have worked at the closure of wounds that in the presence of these organisms suture is almost certainly foredoomed to failure, and, furthermore, that unless the sutures are quickly removed and the wound laid widely open grave danger to the patient is likely to ensue.

Sir Almroth Wright also states, if I understand him correctly, that wounds infected with hæmolytic streptococci, on the surface of which there is abundance of leucocytes—i.e., pus—can be safely sutured if the serum be first carefully removed by dry gauze and the surfaces brought into accurate apposition. This is also contrary to all surgical experience, and there can be no doubt but that anyone who attempts such a proceeding is courting disaster. The results, therefore, of these ingenious experiments do not appear to coincide with the facts of clinical experience, and it is necessary to inquire wherein lies the discrepancy—for discrepancy there certainly is. The accuracy of experimental results vouched for by Sir Almroth Wright is of course beyond question. The clinical facts which I have mentioned are also beyond question, having been independently confirmed by a host of workers, both British and French. The explanation must therefore be that some material difference exists between the conditions of the experiments conducted in Sir Almroth Wright's laboratory and those made every day by surgeons

in the operating theatre and wards. In the laboratory the leucocytes and organisms are confined within the impenetrable barriers of a glass cell. Save by the reproduction of the individuals concerned, no reinforcements can reach this arena, and no undesirable drops of serum can exude into it. He is dealing with a thin stratum of relatively homogeneous material—i.e., serum, leucocytes, and organisms—evenly infected throughout its depth. The surgeon is dealing with tissues of varying resistance and quality, whose blood and lymph supply is endlessly variable from case to case, and which are infected to varying depths from the accessible surface. It does not seem to me to be possible to argue from one to other. A bacteriological study of the walls of infected wounds by means of sections must be an essential item in any attempt to reconcile these laboratory results with the experience of practical surgeons; at present, in spite of the great merit of his contributions to our knowledge, Sir Almroth Wright appears to me to be arguing dangerously upon a false analogy.

It must be noted, also, that the conditions postulated by Sir Almroth Wright for success in the closure of wounds infected by streptococci can seldom be attained in the human body. How is it possible to close any wound in such a way as to prevent the exudation of a few drops of serum between its surfaces? And yet a drop of serum at any point, according to Sir Almroth Wright's own showing, may enable the streptococcus to thrive there and vitiate the result. Such perfect microscopic apposition of surfaces as would be required to fulfil the conditions laid down appears to be beyond our reach. It has been suggested by Sir Almroth Wright himself that failures of primary suture after early excision of wounds may be due to absence of sufficient numbers of leucocytes at this stage. This may be so, but whatever the explanation, the fact remains that the primary suture of wounds which contain, before operation, hæmolytic streptococci will practically always fail.

Full of suggestion as these researches are regarding the further evolution of the treatment of septic wounds, it is necessary to accept the conclusions drawn from them with reserve, for to act too hastily on the principles laid down would involve unnecessary and unjustifiable risk to wounded men. I am, Sir, yours faithfully,

FORBES FRASER,
France, June 18th, 1918. Captain, R.A.M.C.

INFANT MORTALITY AND MOTHERCRAFT.

To the Editor of THE LANCET.

SIR,—Dr. H. W. Pooler's main criticisms in his article on this subject in your issue of July 6th are two in number: (1) that I have endeavoured to eliminate poverty as a cause of infant mortality; and (2) that I have underestimated the value of "mothercraft." With regard to (1), I have certainly never attempted to ignore poverty as a cause of infant mortality and many other manifestations of ill-health. My view is quite clearly expressed that poverty acts mainly as a cause of ill-health by forcing people to live in crowded and insanitary areas, and that under rural conditions it is possible to be earning very low wages and at the same time to enjoy a high degree of health. I illustrated this by comparing the low rates of infant mortality among agricultural labourers in England and the poverty-stricken peasants of Ireland with the high rates prevailing among the much better paid miners. Dr. Pooler is not accurate when he states that the real excess of infant mortality only occurs among the unskilled and casual workers of the town slums and not amongst the skilled and respectable artisans of the better type of working-class neighbourhoods. There is, as a matter of fact, an excess in the infant mortality rates among all classes in large urban districts when compared with agricultural areas, even in the wealthy districts of the West End of London. The slum areas are, however, the worst, and in my opinion as long as people are living in these surroundings they will be unhealthy and their infant mortality rates will be excessive, even though their wages were increased tenfold.

On the second point—the value of mothercraft, and the effect of industrial employment in preventing mothers from looking after their infants—Dr. Pooler emphasises his views by referring to the decline of infant mortality during the Lancashire cotton famine and the siege of Paris, which he attributes to the return of the mothers to their homes and the increase of breast-feeding, and greater opportunities for domestic care and cleanliness. I have not studied infant mortality during the two periods he refers to, but it is very difficult to accept the remarkable explanation he gives. On the other hand, during the war there has been an unprecedented increase in the industrial employment of women, and it is reasonable to suppose that many thousands of mothers have been able to devote far less time to their households and to the feeding of their infants than they would have done under normal circumstances; yet these years have not been accompanied by any rise in the rate of infant mortality.

Dr. Pooler says: "Mothercraft means carefulness, personal cleanliness, clean bedding, clean floors, proper storage, preparation of food (including milk), frugality, thrift, sobriety, early hours, and, above all, breast-feeding." In your leading article, sir, you quote this observation, and you add, "The opportunities for all these things the countrywoman possesses to a far greater extent than her sister in the slums." Again, after referring to insanitary conditions in country cottages, Dr. Pooler says: "It is always possible during part of the 24 hours for the infants to be right away from their noxious influence. On the other hand, in the overcrowded areas of large towns, and in many mining villages, it is a sheer impossibility for the infant to get away from the effects of his own immediate environment or that of his neighbours." Both these statements admit my whole position. It is not nearly so much teaching which the town mother needs as the *opportunities* for carrying out that teaching. The average working-class mother is not such a fool as she is painted. She knows perfectly well that the right things for her baby are good and nourishing food, cleanliness, and healthy surroundings, but in the overcrowded slum districts of our large towns it is often utterly impossible to provide these, where the air is charged with soot and everything rapidly becomes dirty, efficient ventilation of the streets is impossible, the living rooms are small and crowded, baths may be unknown, the milk-supply is unsatisfactory, the storage room for food and domestic utensils is inadequate, and there is nowhere for the children to play except the streets.

I do not wish to depreciate the value of maternity and infant welfare centres any more than I wish to depreciate the teaching of hygiene and the maintenance of hospitals, because I believe that tuberculosis is very largely an environmental disease only to be effectively attacked by destroying vicious surroundings; and nowhere have I suggested that these institutions should be "incontinently scrapped." But I do wish to protest against the tendency to attach an exaggerated importance to maternal ignorance as a cause of infant mortality. I am of opinion that the main cause of excessive infant deaths, as of tuberculosis, malnutrition of school children, and other evils, is overcrowding of houses, congestion of streets, and the absence of large and sufficient open spaces, and so long as these unhealthy areas remain any measures taken can only be regarded as palliative.—I am, Sir, yours faithfully,

The Medical School, Charing Cross Hospital, July 12th, 1918. W. A. BREND.

To the Editor of THE LANCET.

SIR,—Dr. H. W. Pooler's article in your issue of July 6th raises many important questions, and I think that he shows the futility of generalisation in such a complex problem. Those of us who have been doing this work for some years will agree with him in his concluding remarks that "every district has its own problems to solve. In one it may be housing; in another sanitation; in another poverty and underfeeding; in another overfeeding or improper feeding, carelessness, and low morale; and in yet another it may be atmospheric pollution, and in most a combination of some or all of these."

I feel that the work done at infant welfare centres could be made much more convincing if we could show that the infant mortality in a given district was lower amongst those attending the centres than amongst those not attending. This would entail a slight alteration in the statistical tables of the medical officer of health. I feel sure it ought to be done, and the result, I think, would be disconcerting to the polluted atmosphere theorists. Dr. Pooler in his Table VI. gives the weights of infants attending the consultations in both bad and good homes, but we surely do not require tables to convince us of the fact that a child will do better

in a good home than in a bad one. He also gives us the mortality figures amongst the previous children—viz., those who did not attend his consultations—but what we really want to know are the mortality figures of those attending his consultations, and the ages in both sets must, of course, correspond. I am, Sir, yours faithfully,

H. RONALD CARTER, M.D.,
Temp. Capt., R.A.F.

Kensington, W., July 14th, 1918.

QUICK DIAGNOSIS IN MENINGOCOCCUS INFECTION.

To the Editor of THE LANCET.

SIR,—With regard to the paper in THE LANCET of July 13th on the above subject, Captain A. E. Hodgson asks whether the complement fixation by the patient's serum may not be due to antibodies introduced in the curative serum administered. This criticism was anticipated, and an additional communication was sent to THE LANCET to be appended to the original article, but delay in transmission prevented its publication.

The paragraph ran:—

"It may be argued that the results obtained were due to antibodies contained in the curative serum which was administered intrathecally, and that these antibodies had found their way into the blood stream.

Against this view are the following facts. Cases (c), (i), (j), and (o) were tested before serum was given. Case (b), which gave a clean-cut result, was treated only with a pooled serum—i.e., one consisting of the four types—and the same is true, at the time of testing, of 8 out of the remaining 11 cases."

There is a further argument. The blood content of a fair-sized man is some 5 litres. The size of an average intrathecal injection is 30 c.cm. Now, even if it be supposed (disregarding all other body fluids) that the whole of the antibodies find their way into the blood stream, the resulting dilution of the curative serum would be 1 : 166. In the test the lowest dilution of patient's serum was 1 : 50, which gives a final series of dilutions of the curative serum of 1 : 8300, 1 : 16,600, and 1 : 33,200.

We have tested the majority of the curative sera given in these cases and have not got in any complete complement fixation in the lowest of the above dilutions. Apparently, therefore, in cases of meningococcal infection, there is a source additional to the curative serum from which antibodies are produced.—We are, Sir, yours faithfully,

ARTHUR S. G. BELL,
Major, R.A.M.C.;
I. M. HARMER.

Central C.S.F. Laboratory, Caxton-street, S.W., July 20th, 1918.

SEXUAL PERVERSION.

To the Editor of THE LANCET.

SIR,—I was interested to read the excellent letter of Sir Bryan Donkin in your issue of July 13th, and, although I cannot quite agree with him that "inherited perversion" plays the most prominent part among the five classes which I enumerated, I admit that his wide experience as Director of Convict Prisons, as member of the Royal Commission on the Feeble Minded, and as hospital physician must be respected. I think I ought to have used the words "inherited disposition to sexual perversion" instead of "inherited perversion." There are a large number of such cases. The inherited disposition is there, but it is the environment and the taught or inculcated pernicious habits that produce the sexual perversion.

The whole question is most important, and I must still maintain that my other classes are numerically very large and are still increasing.

I am, Sir, yours faithfully,
LIONEL A. WEATHERLY, M.D.

Bournemouth, July 19th.

METHODS OF GENERAL ANÆSTHESIA IN FACIAL SURGERY.

To the Editor of THE LANCET.

SIR,—With reference to Captain T. Lovett's letter in THE LANCET of June 22nd, while I agree that preliminary laryngotomy is almost the ideal method for anæsthesia in facial surgery, at the same time my experience of these patients is that it is not a single operation which is required, but anything from four to twelve. I should very much like to see the condition of a trachea or larynx after it had been reopened so many times. From my two years' experience in working with Mr. P. P. Cole at King George Hospital rectal oil-ether administration seems to be the best, when it is successful, but unfortunately one cannot guarantee the depth of anæsthesia. The next best method appears to be the intratracheal, either with the ordinary intratracheal catheter or Kühn's tube.—I am, Sir, yours faithfully,

HUGH R. PHILLIPS.

Dawson-place, W., July 18th, 1918.

REST AS A FACTOR IN THE HEALING OF LEG WOUNDS.

To the Editor of THE LANCET.

SIR,—One of the chief objects of military surgery is the restoring of men to duty as soon as possible. May I, in connexion with this, draw attention to a point of war hospital practice which I think is of importance—namely, the length of time that is spent in the ultimate healing of wounds of the lower extremity owing to the want of complete rest. It seems to be the general practice to allow a man to be up, on crutches or with sticks, before his wound is finally healed, and it is no uncommon thing for weeks to be occupied in the final healing of a small granulating surface of a leg wound which would have healed in as many days if the man had been kept in bed for a little longer. It is difficult at V.A.D. hospitals to put back to bed a man who has been allowed to be up and about for a fortnight at the war hospital.

The point may seem a small one, but the number of cases involved is very great, and the total number of days lost in the prolonged healing of these leg wounds must be very considerable. If a general rule were suggested in one of those polite circulars ending "for your information, please," to the effect that all patients with leg wounds should be kept in bed until the wound had finally healed, many days in hospital would be saved.

I am, Sir, yours faithfully,
H. CAMERON KIDD.

Bromsgrove, July 19th, 1918.

GÜNZBURG'S TEST.

To the Editor of THE LANCET.

SIR,—Günzburg's test for free hydrochloric acid being so widely used in the examination of test meals and being the only reliable test for that substance, the following modifications may be found useful at the present time.

The Günzburg's test materials consist of phloroglucin, vanillin, and absolute alcohol. Of these, the alcohol is not necessary; the vanillin is easily obtainable and the phloroglucin cannot be obtained at all. The majority of laboratory workers have probably used up all their pre-war stock of phloroglucin, and some may be in need of a substitute. Both orcin and resorcin may be used instead of phloroglucin. The test works equally well with either substance. Orcin is difficult to obtain, even in small quantities, and costs about 2*s.* a drachm. Resorcin is readily obtainable at a cost of 4*s.* 6*d.* an ounce. The amount of substance required for a test is extremely small. A few small crystals of vanillin and of orcin or resorcin dissolved in a drop of the test-meal filtrate and evaporated to dryness give a very clear result. The colour reaction with orcin or resorcin is slightly more purple than with phloroglucin; otherwise the test behaves exactly as with Günzburg's reagent, is positive with very dilute hydrochloric acid in protein solution, and is negative with combined HCl and with lactic acid.

I am, Sir, yours faithfully,
P. N. PANTON, M.A., M.B., B.C. Cantab.,
Clinical Pathologist to the London Hospital.

July 12th, 1918.

"HEALTH RESORTS OF THE BRITISH ISLANDS."

To the Editor of THE LANCET.

SIR,—Owing to war conditions, so great is the difficulty of getting into touch with the original contributors to the pages of the above-named work, that I seek permission through your columns to invite those writers, and others representing health resorts, to send as soon as possible, for a revised edition now in preparation, notes on changes of importance during the past six years, addressed to me.

I am, Sir, yours faithfully,
EDITOR OF "HEALTH RESORTS, &C."

42, Elvaston-place, S.W. 7, July 10th, 1918.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. E. P. W. Wedd, M.C., R.A.M.C. and Yeomanry, was educated at Cheltenham and at Cambridge, and at St. Bartholomew's Hospital, London, and qualified in 1911. He held appointments at St. Bartholomew's and at the East London Hospital for Children, Shadwell. In the early 1900's he was a well-known oarsman, and rowed for his University against Oxford in 1905. On the outbreak of war Capt. Wedd was already in the Essex Yeomanry, and went to the front in November, 1914, in a combatant capacity. Later he transferred to the R.A.M.C. He was mentioned in despatches and awarded the M.C. in April last year.

Previously reported Wounded and Missing, now reported Died of Wounds.

Capt. P. M. MacLachlan, M.C., R.A.M.C., attached Hampshire Regiment. The award of the M.C. was recorded in THE LANCET of Nov. 24th, 1917, p. 805.

Wounded.

Capt. J. M. Forsyth, M.C., R.A.M.C.
Lieut. F. S. Adams, R.A.M.C., attached S. Wales Borderers.
Capt. G. A. Russell, Canadian A.M.C.

Previously reported Missing, now reported Prisoners in German Hands.

Capt. W. G. Harnett, R.A.M.C.
Lieut. A. S. Findlay, R.A.M.C.
Capt. A. C. Hepburn, R.A.M.C.
Capt. W. J. Hirst, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported :—

Corpl. J. Moxon, A.I.F., died of wounds, youngest son of the late Dr. W. Moxon, J.P., of Matlock, Derbyshire.
Lieut. R. A. Edwards, West Yorkshire Regt., died of wounds, youngest son of Lieut. E. H. Edwards, R.A.M.C.
Gunner H. T. Pridham, R.F.A., died from illness contracted on service, son of the late Mr. J. W. Pridham, L.R.C.P., M.R.C.S., of Hillfield, Broadway, Dorset.
Capt. W. R. G. Pearson, R.A.F., accidentally killed through a collision in the air, second son of Dr. S. Pearson, of Clapham-road, London, S.W.

OBITUARY OF THE WAR.

WILLIAM McQUIBAN, M.B., CH.B. ABERD.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain W. McQuiban, who died on active service on May 2nd, aged 44 years, was educated at Gordon College, Aberdeen, where he was Queen's prizeman in marine engineering. He took his medical course at Aberdeen University, qualifying in 1901 and holding appointments as house surgeon at Aberdeen Infirmary and clinical aural assistant at the London Hospital. Since 1902 he was in practice at Stoke Newington. Joining the R.A.M.C. in 1916 he saw service in India and Egypt. While acting as consulting surgeon to a unit in Palestine he was taken ill in April, dying of heart failure. His commanding officer writes of Captain McQuiban that he went out of his way to help others and that no work was too much trouble to him. Captain McQuiban had published work on scientific engineering and on the measurement of blood pressure. His wife, who was the widow of the late J. F. Kendal, F.R.G.S., survives him.

RICHARD AMYAS PRESTON, M.B., B.S. LOND.,

MILITARY CROSS AND CROIX DE GUERRE,
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. A. Preston, who died of wounds on June 7th at the age of 27, was second son of the late A. Eley Preston, M.I.C.E., of St. Mawes, Cornwall. He qualified at the London Hospital, and before taking his M.B., B.S. degree he served in the Balkan War of 1912–13. When the present war broke out he was holding an appointment at the Poplar Hospital, which he resigned on receiving a commission in the R.A.M.C. He went to France early in August, 1914, was twice mentioned in despatches, and was awarded the Military Cross during the retreat from Mons. He also received the Croix de Guerre, and last year he was given the temporary rank of lieutenant-colonel while in command of a field ambulance. He was mortally wounded while attending to the removal of patients under heavy bombardment, and died the same day. Colonel Preston married in 1916 the daughter of the late Charles S. Crawford, of Newcastle-upon-Tyne.

JOHN WATT SENTER, M.B., CH.B., B.SC. EDIN.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant J. W. Senter, who died of wounds on June 9th at the age of 38, was youngest son of the late George Senter, farmer, of Kildrummy, Aberdeenshire. He was educated at Kildrummy Public School and first took up pharmacy, being apprenticed to a pharmaceutical chemist at Mossat. During the South African war he acted as a dispenser in the R.A.M.C., and upon his return to Scotland passed the qualifying examination of the Pharmaceutical Society in 1902. Soon afterwards he started business on his own account as a pharmacist, and whilst so engaged studied medicine at Edinburgh University, graduating M.B., Ch.B., in 1910 and B.Sc. Public Health in 1912. After holding special appointments in the eye and throat departments at the Royal Infirmary, he started in general practice in Edinburgh with every prospect of a useful professional career. Lieutenant Senter joined the Army in June, 1917, and met his death while in charge of an advanced dressing station on the western front. His promotion to captain was due in a few days. His superior officer writes that his work and his companionship will both be missed. Lieutenant Senter leaves a widow and four children.

THE HONOURS LIST.

The following are the statements of service for which the decorations recorded in THE LANCET of Feb. 23rd, 1918, p. 313, were conferred. All are members of the R.A.M.C. except where otherwise stated :—

Second Bar to the Military Cross.

Temp. Capt. ARCHIBALD FULLERTON, M.C.—For conspicuous gallantry and devotion to duty. He worked untiringly under heavy shell and machine-gun fire, attending to the wounded of his own and other units. His fearless conduct undoubtedly saved many lives.

Bar to the Military Cross.

Capt. WILLIAM FOTHERINGHAM, M.C., Spec. Res.—For conspicuous gallantry and devotion to duty. He attended to the wounded in an exposed position under heavy hostile gas-shell fire. Though suffering badly from gas he continued at work with the greatest courage and determination until he was blinded by gas.

Temp. Capt. WILLIAM JOHN KNIGHT, M.C.—For conspicuous gallantry and devotion to duty. He worked continuously during an engagement attending to the wounded under heavy fire, and later went into a village which was being heavily shelled and brought away several wounded men. He went back to the front line after the position had been evacuated and brought back several badly wounded men. He worked with untiring energy throughout the operations and saved many lives.

Capt. THOMAS AINSWORTH TOWNSEND, M.C.—For most conspicuous gallantry and devotion to duty. Although twice wounded he refused to have his wounds attended to, and continued to dress the wounded under a continuous and heavy concentration of high-explosive and gas shells. Not only did he attend the wounded and gassed of his own unit, but rendered aid, under conditions of great difficulty, to wounded of neighbouring battalions whose medical officers had become casualties. His complete disregard of personal danger and splendid devotion were a magnificent example to all.

Capt. FREDERICK WILLIAM LEES, M.C., Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He worked untiringly attending to the wounded and superintending their evacuation. Though his aid-post was continually under heavy shell fire he carried on his work with an energy and cheerfulness which were a splendid example to all. He saved many lives by his devotion to duty.

The Military Cross.

Temp. Capt. ERIC PHILLIP BLASHKI.—For conspicuous gallantry and devotion to duty. He went forward during an engagement and established a dressing-station in an advanced position. He remained at his post under heavy shelling and collected the wounded from an area swept by machine-gun fire. He showed the greatest courage and resource.

Capt. FRANK CHADWICK.—For conspicuous gallantry and devotion to duty. After the troops had been withdrawn he remained with the wounded all night in an advanced position and organised their removal in the face of great difficulties. By his courage and determination he succeeded in getting all the wounded away.

Temp. Capt. THOMAS MAITLAND CRAWFORD.—For conspicuous gallantry and devotion to duty. He was wounded and rendered temporarily unconscious by a shell which mortally wounded the colonel and adjutant of his battalion. As soon as he recovered he attended to their wounds, and remained on the spot without having his own wounds dressed until stretcher-bearers arrived. He reported to brigade headquarters before having his wounds attended to, and showed splendid courage and self-sacrifice.

Temp. Capt. WILLIAM CLAUGHTON DOUGLAS.—For conspicuous gallantry and devotion to duty. While returning from the regimental aid-posts he came under a heavy barrage, and was slightly wounded. Seeing that some men further back had been wounded, he at once went to their assistance, got them under the only available cover, attended to their wounds, and organised stretcher parties for their removal. His prompt and gallant action saved the lives of two seriously wounded men.

Capt. ARCHIBALD McLAREN FERRIE, Spec. Res.—For conspicuous gallantry and devotion to duty. He continually exposed himself to heavy fire in attending to the wounded during an attack. Later, when an officer was wounded and was lying out in an exposed position, he crawled out and brought him in over ground swept by the enemy's fire. His gallantry and courage undoubtedly saved many lives.

4th Class Assistant Surg. JAMES GARNETT GOODMAN, I.S.M.D.—For conspicuous gallantry and devotion to duty. He remained tending the wounded under heavy fire until every case had been evacuated, after which he followed the battery into action. On the previous day, seeing the battery come under an intense shell fire, he at once went up to the guns to render assistance. His coolness, initiative, and keenness were most marked.

Temp. Capt. JAMES HUNTLY LEGGE.—For conspicuous gallantry and devotion to duty in an enemy counter-attack, which almost succeeded in penetrating to his aid-post. With the greatest coolness and courage he continued his work of clearing the wounded, not only of his own battalion, but of other units. Throughout the hostile fire was intense, and it was due to his untiring efforts that so many wounded were quickly and efficiently evacuated.

Capt. REGINALD DEVEREUX MOORE.—For conspicuous gallantry and devotion to duty. He worked continuously for eight days attending to the wounded at an advanced dressing-station, often under shell fire. His organisation of the work was excellent, and by his courage and cheerfulness he inspired all ranks with confidence, which assisted them materially in the performance of their duties.

Capt. JOHN GILBERT MORGAN.—For conspicuous gallantry and devotion to duty. When the advanced dressing-station had been ordered to withdraw he went forward with a party of bearers and successfully cleared a number of wounded from the regimental aid-posts. The operation was carried out under continuous shell and machine-gun fire.

Temp. Capt. JOHN OSCAR THOMAS.—For conspicuous gallantry and devotion to duty. He dressed a wounded officer and man under heavy fire and got them to a place of safety. He showed great coolness and courage.

Temp. Capt. PHILIP HEWER WELLS.—For conspicuous gallantry and devotion to duty. He attended to the wounded of several units who were lying out in an exposed position under fire. He worked throughout the night, often under an intense bombardment of gas and H.E. shells, and by his courage and self-sacrifice saved many lives.

Temp. Capt. ERNEST WILLIAM GILMORE YOUNG.—For conspicuous gallantry and devotion to duty. He collected and dressed the wounded in an exposed position under heavy fire, and remained on the spot after the withdrawal of the regiment until all the wounded had been brought in.

Capt. GAVIN YOUNG, Spec. Res.—For conspicuous gallantry and devotion to duty in attending to the wounded under heavy machine-gun fire. He worked up to the leading wave and searched the whole ground for wounded under continuous fire, and owing to his exertions all the wounded were evacuated with great rapidity. Later he showed great courage and devotion to duty in rescuing wounded from destroyed dug-outs under shell fire.

Capt. GEORGE MAY FOSTER, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He was in charge of the evacuation of the wounded from the front line during the operations, and set a splendid example to his stretcher-bearers by his courage and determination. He led a party to remove several stretcher cases under heavy shell fire, and though wounded himself he attended to their wounds and arranged their removal.

Capt. ALFRED STANNAGE PORTER, Canadian A.M.C.—For conspicuous gallantry and devotion to duty. He dressed many wounded during the operations, working in the open under intense fire, and set a splendid example of courage and self-sacrifice.

Lieut.-Col. D. L. IRVINE (late R.A.M.C.), at present working on the Western front under the French Red Cross, has been awarded the Croix de Guerre for his services with Motor Ambulance, Section 10, with the French Army.

THE LONDON RECRUITING BOARDS.

On the invitation of Sir Charles Bedford, the Commissioner of Medical Services for the London Region, 200 of the chairmen and members serving on the London recruiting boards met the Chief Commissioner, Sir James Galloway, K.B.E., C.B., in the Caxton Hall on Tuesday afternoon last. Sir James Galloway took the chair, and was accompanied by Sir Charles Bedford and Sir John Collie, representing the Ministry of Pensions. Sir Charles Bedford, in his introductory remarks, mentioned that the boards in the London region had had to be increased from 20 in March last, when he took charge, to 54 to-day, and offered personal thanks for the good work done. Sir James Galloway welcomed the opportunity of congratulating the chairmen and members of the London recruiting boards in the name of the Ministry of National Service for the whole-hearted manner in which they had carried out their very arduous duties. He added that neither on the administrative or executive side had perfection yet been attained and that all efforts must be put forth to improve their organisation and the quality of their work, while a comparatively quieter time allowed them to discuss matters among themselves. Sir James Galloway pointed out that much of the work was pioneer, while the boards were for the most part drawn from private practitioners who in the past had to deal only with the sick and diseased, and who had not had full opportunity of knowing what the normal condition of health was in reference to climate, nature of work, crowded surroundings, and other conditions of life. Conscription, he said, had given the profession the first real chance of studying these questions, and advantage should be taken of it to the full with a view to the improvement in the general health of the people by legislation or otherwise. Sir John Collie referred to the bearing which efficient medical examinations and grading would have when pensions were dealt with.

MEDICAL GRADING OF OLDER MEN.—A Memorandum (R. 218) has been issued by the Local Government Board and the Scottish Office to tribunals, instructing them to deal with the medical grading of men of the older ages in accordance with the statement made in the House of Commons on July 8th by the Minister of National Service (see THE LANCET, July 13th, p. 63). The Memorandum adds:—

> The requirements of the forces for men of all ages in Grade 1 and for men of the former military ages in Grade 2 are great and urgent. There is also a considerable demand for Grade 2 men of the new military ages, and for Grade 3 of the former military ages, except men who have been found by the medical boards to be fit only for sedentary work and who are without technical skill of a kind required in the Services.

LONDON HOSPITAL MEDICAL COLLEGE.—The following awards have been made to students of the London Hospital Medical College during the session 1917–18:—

Medical prize, £20, S. N. Sennett; honorary certificates: E. Miller and A. B. K. Watkins; Obstetric prize, £20, J. C. Ryder Richardson; honorary certificate: J. Fanning; Andrew Clark prize in Clinical Medicine and Pathology, £26, A. B. K. Watkins; honorary certificates: S. N. Sennett and E. Miller; Sutton prize, £20, A. B. K. Watkins; Anderson prizes in Elementary Clinical Medicine, £3, M. C. Hartley and R. A. Madgwick; honorary certificates: A. R. Crane and J. J. Coghlan; prizes in Elementary Clinical Surgery, £5, E. L. Sergeant, M. Marcus, M. C. Hartley, and F. F. Langridge and C. W. Tomkinson (equal—prize divided); Letheby prize in Organic Chemistry, £10, S. Sandler.

DONATIONS AND BEQUESTS.—By will the late Miss Ada Katharine Agnes Bickersteth, of Hunton Bridge, Herts, left, among other bequests, £500 each to the Middlesex Hospital for the Cancer Wards, the Home at Stoneygate-road, Leicester, Leicester Royal Infirmary, Watford District Hospital, and the Meath Home for Epileptics.

Obituary.

HENRY GEORGE PLIMMER, M.R.C.S. ENG., F.R.S.,

PROFESSOR OF COMPARATIVE PATHOLOGY AT THE IMPERIAL COLLEGE OF SCIENCE.

Professor Plimmer, whose death we chronicled at the time of its occurrence, was an exceedingly interesting figure in the medical world, and responsible therein for much good and varied work. The following detailed account of his career has been compiled from intimate sources.

Henry George Plimmer, the only son of Dr. George Plimmer and Eliza Eyres, was born on Jan. 29th, 1857, in Melksham, Wilts. His father died whilst he was a boy, and young Plimmer, after leaving school in 1870, became a clerk. Not being satisfied with such an outlook on life, he wrote in 1877 to Dr. J. H. Galton, who had been his father's assistant, concerning a career in medicine, and Dr. Galton invited him to come to him as assistant—the unqualified assistant's post being at that time a recognised mode of entering the medical profession. He lived with Dr. Galton at Norwood, at first doing the dispensing and book-keeping, but gradually helping in the dispensary part of the large practice of Galton and his partner Sidney Turner. In a few months he passed the preliminary examination of the College of Surgeons and Apothecaries' Society, and entered Guy's Hospital as a perpetual student in October, 1878. He was made prosector of the Royal College of Surgeons in 1882, became L.S.A. in October of the same year, and M.R.C.S. in January, 1883. Many of his dissections are to be seen in the Museum of the College of Surgeons, but he could not proceed to the Fellowship examination owing to the exacting work of a large general practice. In 1885 he was made a partner, but retired from general practice seven years later so as to devote himself to bacteriology and research, which he began with Professor E. M. Crookshank at King's College, London. Microscopy and histology greatly interested him in his student days; the first society of which he became a member was the Royal Microscopical in 1883. His early microscopical preparations were deservedly admired, and much attention was attracted by the inclusions in cancer cells, subsequently called Plimmer's bodies, which were differentiated by him in October, 1892, from the then known degenerations by means of a technique which he had devised. About this time he met Armand Ruffer, who was working at the same subject, and at Ruffer's suggestion they worked together at the laboratories of the Royal College of Surgeons. He was associated with Ruffer until illness compelled Ruffer to resign from the British Institute of Preventive Medicine, whither they had gone on its establishment in 1893. Some of the early work on diphtheria in this country was carried out by them there.

From this time on Plimmer occupied a series of important posts. He became pathologist to the Cancer Hospital in 1894, bacteriologist and lecturer on bacteriology at St. Mary's Hospital in 1896, and succeeded Silcock there as pathologist and lecturer on pathology in 1899, resigning this post to take charge of the cancer laboratories at the Lister Institute, started by Lord Iveagh, in 1902. Since 1898 he had been working at trypanosomes, partly in association with Sir J. Rose Bradford, and in 1906 undertook the research work on trypanosomiasis which was organised and directed by the Tropical Diseases Committee of the Royal Society. At the same time he was made a member of that committee. From 1907 to 1917 he was pathologist to the Zoological Society. His contributions to science were at last recognised in 1910, when he was elected a Fellow of the Royal Society. He accepted the professorship of comparative pathology at the Imperial College of Science and Technology in 1915, was elected a member of the War Office Tetanus Committee in 1916 and later of the Trench Fever Committee. He was actively engaged with the work of his professorship and the work of the War Office committees until a few weeks before his death, being very largely concerned with the recent discoveries relating to trench fever. In addition to these varied appointments Plimmer was a Fellow of many scientific and medical societies. He presided over the Royal Microscopical in 1911–12; he was visitor of the Royal Institution in 1914–16; a member of council of the Linnean and of the Association of Economic Biologists in 1917–18.

Plimmer's adaptability is worthy of special note. During his partnership with Turner and Galton he did surgical work of an original nature. Two cases—one of hysterectomy, the other of ectopic gestation—described in THE LANCET of 1888 were the first of their kind in this country. A paper on quinsy and rheumatism appeared in the *British Medical Journal* of 1886. His work on cancer dates from 1892. Following the note on the Parasitic Protozoa lately Found in Cancer, he further studied at the Cancer Hospital the various cell inclusions and during his appointment at St. Mary's Hospital he isolated a yeast from an ulcerating cancer. These yeast cells were very like cell inclusions, and the fact that they caused tumours in animals led to the hope that here was the long-looked-for cause of cancer. It was a disappointment, for though they were found in several cancers, they did not produce genuine cancer in animals, and were, no doubt, accidental infections. Comprehensive reviews on cancer from his pen were: On the Microscopical Diagnosis of Benign and Malignant Growths of the Cervix Uteri (*British Gynæcological Journal*, 1895); Ætiology and Histology of Cancer (*Practitioner*, 1899); the Parasitic Theory of Cancer (*British Medical Journal*, 1903). Since 1899 he worked mainly upon blood parasites, particularly the trypanosomes found in the tsetse fly disease, Gambia fever, sleeping sickness, describing three new species of the genus Toxoplasma.

Plimmer had a special gift for music. It was his recreation through life, and he was himself a remarkable pianist. He was also a connoisseur of the Italian School of Painting, while literature also occupied much of his time, although his scholarship is only dimly seen in his published works, such as "Omariana," "Bedullus Immortalis," and various presidential addresses. He delighted in intercourse with his fellow men, showing his kind and sympathetic nature to all, and was a brilliant conversationalist. The Omar Khayyam Club, of which he was some time president, afforded him abundant opportunities of meeting his friends, and he was one of those mainly concerned in founding the Lucretian Club, of which he was secretary for a number of years. Plimmer's life was full of many interests, and he found room for them all.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

To be temporary Surgeons: A. W. Cocking, D. A. Knight, N. Macleod, J. D. Byrd.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Probationer J. W. Scharff has been invalided with a pension and the retention of his rank after two years' service.

ARMY MEDICAL SERVICE.

Temp. Col. Sir Robert Jones (Major, R.A.M.C., T.F.) to be temporary Major-General.

Temp. Lieut.-Col. John M. Cowan (Major, R.A.M.C., T.F.) to be temporary Colonel.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. J. W. H. Houghton relinquishes the temporary rank of Colonel on re-posting.

Major S. B. Smith retains the acting rank of Lieutenant-Colonel whilst employed as Assistant Director of Medical Services of an Army.

Capt. J. W. C. Stubbs to be acting Lieutenant-Colonel whilst in command of a Medical Unit.

J. V. G. B. Tighe to be temporary Lieutenant-Colonel whilst serving at Gateshead War Hospital, Stannington.

Lieut.-Col. C. Garner, retired pay, to be acting Colonel whilst specially employed.

Capts. W. H. S. Burney and T. B. Nicholls and Temp. Capt. H. Moore relinquish the acting rank of Lieutenant-Colonel, and revert to the acting rank of Major, with pay and allowances of their substantive rank.

Temp. Major J. M. Nettleton, Canadian A.M.C., to be temporary Lieutenant-Colonel.

Temp. Capt. A. R. Jordon relinquishes the acting rank of Major on re-posting.

To be acting Majors: Temp. Majors H. F. Woolfenden, W. S. Dickie, R. Dick; Capts. G. F. Allison, C. Scales, W. E. Marshall, A. P. O'Connor, P. T. Priestley; Temp. Capts. E. B. Sunderland, W. De M. Peyton, T. Bragg, W. H. Fleetwood, D. C. Taylor, E. F. C. Dowding, J. A. C. Roy, C. Mackenzie, J. G. Duncanson, H. Stokes, E. L. Mackenzie, J. H. Legge, L. H. C. Birkbeck; Lieut. (temp. Capt.) J. La F. Lauder.

J. C. Webb to be temporary Major.

Capt. T. D. Inch, from R.A.M.C., Spec. Res., to be Captain.

The undermentioned temporary Lieutenants to be temporary Captains: G. S. Robinson, H. Topham, F. Heatherley, A. Barrett, A. T. Moon, J. W. O'Farrell, A. C. Brown.

To be temporary Captains: Capts. R. W. B. Gibson (South African M.C.) and T. L. Harrison (Canadian A.M.C.), T. H. Twigg, T. Milling, W. G. Ridgway, F. W. Jones, J. E. R. Orchard, H. E. C. Fox (late Surgeon, R.N.), D. T. H. Croly, E. Maynard, W. A. Russell, T. J. Buckley, S. P. Snook.

Temp. Hon. Lieut. H. F. Bold-Williams to be temporary Honorary Captain whilst serving with No. 8 Red Cross (Baltic and Corn Exchange) Hospital.

Temp. Hon. Lieuts. P. D. Spohn and E. A. Cayo to be temporary Honorary Captains.

P. M. Turnbull, late temporary Captain, is granted the honorary rank of Captain.

To be temporary Lieutenants: L. H. McConnell, A. L. Lynch, N. F. Sinclair, D. D. Farquharson, R. M. Mainwaring-White, A. W. MacK. Sutherland, A. Prentice, B. W. Lacey, J. Devine, F. H. Nixey, O. Eccles, A. S. Ransome, E. D. D. Davis, B. A. McSwiney, A. H. Ward, J. Moore, A. H. Marsh, G. Ap Thomas, R. A. MacArthur, W. Daunt, C. K. T. Hewson, P. N. Twomey, N. C. Fischer, N. J. Newbould, W. H. W. Mewhirter, W. E. Thompson, A. V. Moberly, H. G. Browning, G. S. Robinson, F. C. Mann, F. P. Hearder, C. H. Steinbach, A. W. Hare, F. W. Daniels, S. B. Turner, D. Davie, M. Baronov.

Officers relinquishing their commissions: Temp. Capts. E. L. Massiah, G. H. Brown (granted honorary rank of Captain), J. Lindsay, T. D. McLaren, F. M. Walker, A. Weigall, E. G. H. Weir, H. Saunders and R. McI. Muir (granted honorary rank of Captain), W. Rogerson, M. Hooper and J. M. Johnston (on account of ill-health contracted on active service and are granted the honorary rank of Captain). A. L. George; Temp. Lieuts. H. V. Mitchell, W. Martin, W. M. Fergusson (on account of ill-health).

SPECIAL RESERVE OF OFFICERS.

Capt. I. D. Evans relinquishes the acting rank of Major on re-posting.

Captains to be acting Majors: T. Lindsay, J. B. Scott, W. W. Shorten.

Lieutenants to be Captains: J. Scott, J. Adams, J. C. C. Howe, A. B. MacDougall, P. A. Stewart, O. M. Mirylees, W. L. Agnew.

Capt. P. W. Mathew to be acting Major while specially employed.

J. C. Coutts, from St. Andrews University O.T.C., to be Lieutenant.

TERRITORIAL FORCE.

Capt. Charles L. Tireman relinquishes his commission.

Captains to be acting Majors whilst specially employed: J. M. Smith, T. J. T. McHattie, A. Radford, Lieut.-Col. J. Clay, L. M. V. Mitchell, G. G. Middleton, G. B. Buchanan, W. T. Torrance, J. Browne, P. S. Martin, D. W. Reese, J. J. E. Biggs, J. H. Robinson, C. S. Wink, F. Ward, E. B. Hinde, M. Morris, L. Milton, C. E. Petley, A. B. P. Smith, W. F. Mackenzie, R. S. Taylor, C. S. P. Black, J. A. H. Aitken, R. G. Walker, C. H. K. Smith, A. F. B. Shaw, C. W. C. Myles, F. A. W. Drinkwater, W. J. Richards, C. Kerr, D. Lamb, J. Blackwood, J. J. Rainforth, A. P. Watson, W. Dyson, M. U. Wilson, W. T. Gardiner, L. West, A. L. S. Tuke, W. T. Ritchie, J. G. Morgan.

Captains (acting Majors) relinquishing the acting rank of Major on ceasing to be specially employed: A. F. B. Shaw, J. G. Morgan, A. J. Drew (seconded for duty overseas).

Capt. (acting Major) R. S. Taylor, Capt. (acting Lieut.-Col.) D. Shannon, Capt. (acting Major) A. N. S. Carmichael, and Capt. (acting Major) G. L. K. Pringle relinquish their acting rank on ceasing to be specially employed.

Capt. (acting Major) W. L. Robertson to be acting Lieutenant-Colonel whilst commanding a Field Ambulance.

Capt. (Brevet Major) J. Ewing to be acting Major whilst specially employed.

Capt. H. L. Driver is seconded for duty with London District.

Capt. (acting Lieut.-Col.) J. M. Hunt relinquishes his acting rank on ceasing to command a General Hospital.

Capt. H. Buck is seconded for duty with a General Hospital.

Lieut. (temp. Capt.) A. Leitch, and Lieuts. G. Bryce and W. V. Barritt to be Captains.

Lieuts. A. G. Harrington, J. Dull, G. N. F. Reddan, T. H. Savory, D. Smith, and A. Sykes are seconded for duty with the R.E.

TERRITORIAL FORCE RESERVE.

Capt. G. L. K. Pringle, from R.A.M.C., to be Captain.

ROYAL AIR FORCE: *Medical Branch.*

L. S. Hooper (temp. Capt., R.A.M.C.) is granted a temporary commission as Captain, and to be temporary Major whilst specially employed.

R. G. Maglione, I. M. Thomson, and A. H. Todd are granted temporary commissions as Captains.

G. Dunderdale, J. P. Hennessy, G. W. Harbottle, F. Gill, J. S. Harbinson, J. J. O'Mullane, M. J. Whelton, and A. G. Graham are granted temporary commissions as Lieutenants.

INDIAN MEDICAL SERVICE.

The King has approved the admission of the undermentioned:—To be Lieutenants: Hira Singh Anand, Sunda Dass Sondhi. To be temporary Major: Percy Charles Woollatt. To be temporary Lieutenants: Nariman Sorabji Kotwal, Kaikhusroo Rustomji Dalal, Susanta Kumar Sen, Kantilal Kalyanji Mankodi, Gopal Narayan Khanna, Amar Nath Madhok, Bantwal Shankar Rau, Waris Khan, Eustace Trevor Neave Taylor, Keki Sorabji Bhiwandiwala, Keith Montague Woodruff, Dya Ram Thapar, Albert Victor Lopes, James Henry Barrett, Shaikh Ghulam Mohamed, George Patrick de Sibra, Jugal Kishor Adhya, Yedatore Venkoba Krishnamoorthy.

URBAN VITAL STATISTICS.

(Week ended July 13th, 1918.)

English and Welsh Towns.—In the 93 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had increased from 11·4 to 19·0 per 1000 in the four preceding weeks, further rose to 21·1, the highest rate recorded in any week of the current year. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 18·4, or 1·1 per 1000 above that recorded in the previous week; among the remaining towns the rates ranged from 6·2 in Ilford, 7·0 in Hornsey, and 7·1 in Bath, to 40·2 in Barnsley, 40·3 in Wakefield, 46·0 in Sunderland, 46·9 in Rochdale, and 49·4 in Middlesbrough. The principal epidemic diseases caused 330 deaths, which corresponded to an annual rate of 1·0 per 1000, and included 144 from whooping-cough, 84 from measles, 46 from diphtheria, 35 from infantile diarrhœa, 18 from scarlet fever, and 3 from enteric fever. Whooping-cough caused a death-rate of 1·5 in Warrington and in Sunderland, 1·6 in Ealing, 1·8 in Gateshead, and 2·4 in Walsall; measles of 1·5 in Sunderland, 1·6 in Rotherham, and 2·2 in Wakefield; and scarlet fever of 1·7 in St. Helens. The 821 cases of scarlet fever and 1070 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 9 and 76 below the respective numbers remaining at the end of the previous week. The 1422 deaths from all causes in London included 287 from influenza, of which 168 were of persons aged 15 to 35 years. The causes of 61 deaths in the 96 towns were uncertified, of which 13 were registered in Birmingham, 5 in Manchester, and 4 each in Liverpool and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 15·0, against 11·5 and 13·9 per 1000 in the two preceding weeks. The 260 deaths in Glasgow corresponded to an annual rate of 12·2 per 1000, and included 11 from measles, 6 from whooping-cough, 3 from infantile diarrhœa, and 1 each from enteric fever and diphtheria. The 115 deaths in Edinburgh were equal to a rate of 18·0 per 1000, and included 2 from diphtheria and 1 from whooping-cough.

Irish Towns.—The 250 deaths in Dublin corresponded to an annual rate of 32·7, or 9·4 per 1000 above that recorded in the previous week, and included 2 from whooping-cough and a fatal case each of measles, scarlet fever, and infantile diarrhœa. The 213 deaths in Belfast were equal to a rate of 28·3 per 1000, and included 10 from whooping-cough, 4 from infantile diarrhœa, and 1 from measles.

(Week ended July 20th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 18·0, against rates increasing from 11·4 to 21·1 per 1000 in the five preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 15·2, or 3·2 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 6·4 in Ipswich, 7·6 in Edmonton, and 8·9 in Hornsey, to 32·8 in West Hartlepool, 34·2 in Warrington, and 43·5 in Barnsley. The principal epidemic diseases caused 301 deaths, which corresponded to an annual rate of 0·9 per 1000, and included 105 from whooping-cough, 103 from measles, 41 from infantile diarrhœa, 31 from diphtheria, 14 from scarlet fever, and 7 from enteric fever. Whooping-cough caused a death-rate of 1·8 in Walsall, 2·0 in Aberdare, 2·3 in Grimsby, and 4·6 in Warrington; and measles of 2·0 in Barrow-in-Furness, 2·4 in Walsall, 2·6 in Sunderland, and 4·4 in Lincoln. The 836 cases of scarlet fever and 1016 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 15 above and 54 below the respective numbers remaining at the end of the previous week. The 1171 deaths from all causes in London included 192 from influenza, of which 74 were of persons aged 15–35 years. The causes of 44 deaths in the 96 towns were uncertified, and included 6 in Birmingham, and 5 each in Liverpool, Manchester, and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had increased from 11·5 to 15·0 per 1000 in the three preceding weeks, further rose to 17·4 per 1000. The 340 deaths in Glasgow corresponded to an annual rate of 15·9 per 1000, and included 9 from whooping-cough, 8 from infantile diarrhœa, 7 from measles, 4 from diphtheria, and 3 from enteric fever. The 106 deaths in Edinburgh were equal to an annual rate of 16·6 per 1000, and included a fatal case each of diphtheria and whooping-cough.

Irish Towns.—The 208 deaths in Dublin corresponded to an annual rate of 27·2, or 5·5 per 1000 below that recorded in the previous week, and included 5 from whooping-cough, 2 from infantile diarrhœa, and 1 from diphtheria. The 152 deaths in Belfast were equal to a rate of 20·2 per 1000, and included 4 from whooping-cough, 3 from infantile diarrhœa, and 1 each from enteric fever and diphtheria.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held at 2 P.M. on Wednesday, Friday, and Saturday, and also at 10 A.M.

Medical News.

UNIVERSITY OF LONDON.—At examinations for internal and external students held recently the following candidates were successful:—

M.D. EXAMINATION.

Branch I., Medicine.—Arthur Joseph Eagleton, B.S., Guy's Hospital; Innes Hope Pearse, B.S., London School of Medicine for Women; William Norman Pickles, B.S., University of Leeds; and Gabriel Francis Rodrigues, B.S., University College Hospital.

Branch VI., Tropical Medicine.—Robert Yelverton Stones, B.S., London Hospital.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

UNIVERSITY OF GLASGOW.—The following candidates received their degrees on July 20th:—

Bachelors of Medicine and Bachelors of Surgery (M.B., Ch.B.).—*With honours:* John Gordon Harrower and William Ralston Duncan Hamilton. *With commendation:* Morris Hyman and Margharita Mary Lamont Couper. *Ordinary degrees:* Carl Otto Anderson, Ellen Davidson Anderson, John David Arthur, William Barras, Donald Cameron Bowie, William George Burns, Michael John Cahalane, Hugh Auld Cochrane, Edward Mitchell Erskine Cumming, John Freeland Cunningham, Andrew Murdoch Davidson, Archibald Browning Smith Drysdale, William Edgar, Duncan Finlayson, Grace Anderson Fleming, George Gordon, Adam Smith Goudie, Jane Evelyn Hanson, Lillias Beverley Hardie, Andrew Henderson, John Irving, Robert Paterson Jack, James Campbell Laurie, Jacob Lipsey, Alan James Macartney, Duncan MacColl, Isabella Quarrier McFadzean, Thomas McGowan, John William Mackay, Andrew Aird McLaughland, Donald Maclean, William Riddock McLinden, Findlay Kerr Macmillan, John Muil Melvin, Florence Frances Mitchell Milne, William Napier, Bryce Frood Niblock, Elizabeth Park Young Paterson, Norman Bligh Peacock, Robert James Peters, John Browning Potter, Rahmat Ullah Qureshi, William Scotland, Katherine Scott, Margaret Marion Catherine Steedman, James Alexander Walls, Thomas McSkimming Wilson, and George Macfeat Wishart.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on July 9th, 26 cases were considered and £244 12*s.* voted to 24 of the applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 60, of L.S.A. Lond. who practised at Warwick and died in 1899. Only permanent income £26. Receives a little from occasional boarders. Rent and rates £24. Suffering at present from a nervous breakdown. Voted £12 in 12 instalments.—Daughter, aged 68, of M.R.C.S. Eng. who practised at Brixton and died in 1878. Was left totally unprovided for, and now, through advancing years, unable to work. Lives with a widowed sister, who cannot afford to keep her. Voted £12 in 12 instalments.—Widow, aged 48, of M.B. Edin. who practised at Ballindalloch and died in 1910. Was left without income with four children, now ages 11-19. Receives £21 per annum from other funds. Recently had a situation, but has been compelled to give it up with a view of looking after the younger children. Relieved six times, £60. Voted £10 in two instalments.—Widow, aged 62, of L.R.C.P. & S. Edin. who practised at Balham and died in 1913. Was left entirely without means, and health not sufficiently good to enable her to do regular work. Lives rent free, but will shortly have to look for a room, for which she will have to pay. Relieved five times, £30. Voted £12 in 12 instalments.—Daughter, aged 63, of L.F.P.S. Glasg. who practised at Mauchline and died in 1883. Has been in bad health for a long time. Only income £15 from another charity and the amount given by the Fund. Relieved 11 times, £166. Voted £12 in 12 instalments.—Daughter, aged 66, of M.R.C.S. Eng. who practised in Liverpool and died in 1883. For some years acted as matron of a home, but owing to rheumatism and deafness had to give it up. Total income £37. Lives with a sister, who shares the rent. Relieved four times, £46. Voted £12 in 12 instalments.—Daughter, aged 61, of M.R.C.S. Eng. who practised at Lacock and died in 1898. Largely dependent on dividends, which she and her two sisters receive from investments, but owing to the war these have greatly depreciated. Takes occasional boarders. Relieved three times, £30. Voted £10 in two instalments.—Daughter, aged 66, of M.R.C.S. Eng. who practised at Dorchester and died in 1892. At present is living in Paris with a widowed sister, but is anxious to get away from there on account of air raids. Only income £10 a year from her brother. Relieved once, £10. Voted £15.—Wife, aged 52, deserted by husband, an M.R.C.S. Eng. who practised at Bournemouth. Was left with one daughter, now aged 24, who is earning 27*s.* a week. Applicant's health is bad, which prevents her from working. Relieved five times, £50. Voted £12 in 12 instalments.—Widow, aged 69, of M.D. Glasg. who practised at Dennistoun and died in 1876. Applicant lives with a married daughter and is a permanent invalid. Daughter unable to keep her. Only income £12 from another charity. Relieved four times, £48. Voted £12 in 12 instalments.—Widow, aged 53, of L.R.C.P. & S. Edin. who practised at New Quay and died in 1893. Was left with two young children, both of whom are now in the Navy and allow her 15*s* a week. Applicant's health is bad, and she recently fractured her leg. Relieved 15 times, £149. Voted £12 in 12 instalments.—Daughter, aged 62, of M.R.C.P. Edin. who practised at Holloway and died in 1884. Through ill-health applicant is unable to work. Has a pension from another charity of £40 and pays 16*s.* a week for board and lodging. Relieved 14 times, £127. Voted £12 in 12 instalments.

Subscriptions may be sent to the acting hon. treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, W.1.

Mr. Richard R. Cruise, C.V.O., has been appointed surgeon-oculist and Sir Harry Baldwin surgeon-dentist to the King.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JULY 17TH.

Naval Medical Service.

Major NEWMAN asked the Secretary to the Admiralty what response had been obtained to the recent Admiralty invitation to the temporary surgeons to join the permanent list of the Royal Navy.—Mr. MACNAMARA replied: The actual number of applicants to transfer from the temporary to the permanent list of the Royal Navy since the promulgation of the Order is 18, and of these 15 will probably be eligible.

Major NEWMAN asked whether the right honourable gentleman was aware of the dissatisfaction that prevailed among members of the permanent medical service owing to the fact that surgeons were now doing the duties formerly carried out by fleet- and staff-surgeons without extra pay or acting promotion as in other branches of the service, and that the large influx of temporary surgeons had not reduced the time served for promotion in the permanent service; was he aware that when similar conditions prevailed in the Royal Army Medical Corps all subaltern officers of the permanent list were promoted forthwith; and what did he propose to do to remedy these grievances.—Mr. MACNAMARA answered: The Admiralty is not aware of any dissatisfaction in this respect, nor has any previous representation on the subject been received. The whole question of pay, prospects, and other matters in connexion with the medical branch is now under the consideration of the Board of Admiralty. This particular question of acting rank will also be dealt with. The influx of temporary surgeons has no influence on the conditions of promotion in the permanent service. I note the reference to what occurs in the Royal Army Medical Corps, but the case of subaltern officers in that corps does not form a parallel, as the Royal Naval officers affected are of the relative rank of captain or above.

Medical Grading.

In the course of an answer to Mr. H. SAMUEL, Sir AUCKLAND GEDDES said: Formerly a certain number of men were placed in Grade III. in order to provide an opportunity for diagnosing the affection from which they were suffering. Under the instructions now current a man who is temporarily unfit for posting on account of some acute transient affection (e.g., measles or scarlet fever), or whose case requires some special test, is not graded, but is notified that he must again attend for the completion of his examination and grading upon a definite date at an appropriate interval of time. In all other cases men are now placed at once in the grade for which they are considered physically fit. Men who are found to be permanently and totally unfit for any form of military service are given a final discharge.

Mr. ALBION RICHARDSON asked whether in order to give to all men called up, irrespective of their financial position, the same chance of being correctly graded he was prepared to make arrangements, or to recommend that arrangements should be made by the appropriate Government department, to enable a man who had been attended by his panel doctor in recent illness and who could not afford to pay such doctor for a certificate stating his recent medical history, to obtain such a certificate free of charge for production to the medical board to assist them in grading him, in the light of his recent medical history so certified to.—Sir A. GEDDES replied: I fully appreciate the importance of the point raised in my honourable friend's question. At present the instructions are that in cases of doubt as to the man's medical history chairmen of medical boards are to consult the recruit's private medical attendant. The difficulty connected with this is that so many medical men are serving with the Forces that in a very large number of cases the man's ordinary medical attendant, quite irrespective of the man's financial position, cannot be referred to. It was largely to meet this difficulty, which was fully recognised last autumn, that the systems of re-examination by National Service Medical Boards, of specialist examination in connexion with these boards, and of appeal medical assessors were introduced.

Housing of the Working Classes.

Answering Sir S. ROBERTS, Mr. HAYES FISHER said: The total number of local authorities in England and Wales which have intimated to me that houses for the working classes are required in their areas is 1103. Owing to the form in which the replies of local authorities have been given it is not possible to state exactly how many houses they consider necessary, but the number probably exceeds 300,000. In 510 cases the number of houses required exceeds 100.

THURSDAY, JULY 18TH.

Medical Establishments in France.

Major CHAPPLE asked the Under Secretary for War whether the Army Council had now considered the report of the

Committee on Medical Establishments in France, and whether any action was to be taken in the matter.—Mr. MACPHERSON replied: Yes, sir, the report has been considered, and such action as was desirable has been taken.

Medical Officer Prisoners in Turkey.

Colonel BURN asked the Financial Secretary to the War Office whether British medical officers, both of the Royal Army Medical Corps and of the Indian Medical Service, who were prisoners in Turkey were receiving smaller pay and allowances than when they were on active service in Mesopotamia or elsewhere, although they were still working as doctors; whether he would arrange that they be given the full pay and allowances which they drew on active service on receipt of certificates from them, or on other evidence, that they had had medical charge of prisoners; and whether those of them who drew free rations while on active service would be given an allowance in lieu for the period covered by such certificates or evidence.—Mr. FORSTER answered: British officers, both of the Royal Army Medical Corps and of the Indian Medical Service, are on their release or exchange credited with the full Indian pay of their substantive appointment for any period of their captivity during which they certify that they were fully employed with the care of British or Indian sick or wounded. Ration allowance is only issuable to officers when they are on active service.

Treatment of Nerve Strain.

Sir A. GRIFFITH-BOSCAWEN (Parliamentary Secretary to the Ministry of Pensions), replying to Colonel YATE, said: For functional nerve disorders six homes of recovery have been established as follows: One in London for 120 patients; one in Leicester for 60; one near Manchester for 100; one in Edinburgh for 30-60; one in Dublin for 33; and one in Belfast for 62. All these have workshops or provide other forms of occupation, such as gardening. There is no connexion with lunacy administration or lunacy staff. The records of my department do not, unfortunately, enable me to state how many men have passed through their hands since they were opened. I should, perhaps, add that no special provision has been made for men suffering from uncertifiable mental deficiency who are not suitable for admission to one of the homes of recovery. The number of cases of this nature which have been brought to my notice is not large, and, where necessary, arrangements have been made with one or other of the existing mental homes which accept uncertifiable cases.

Medical Examination of School Children in Scotland.

Mr. MUNRO (Secretary for Scotland) informed Colonel G. COLLINS that schemes for the medical examination of school children had been adopted by the whole of the school boards in Scotland, and, except in the county of Shetland, had actually been brought into operation. In some districts, however, the work had been temporarily interrupted owing to depletion of the medical and nursing staffs through the urgent demands of the war.

Lanarkshire Housing Scheme.

Mr. DUNCAN MILLAR asked the Secretary for Scotland whether arrangements had now been completed with the Treasury for the carrying out of the Lanarkshire housing scheme which was adjusted some months ago.—Mr. MUNRO replied: The Treasury has agreed to the scheme subject to certain conditions which will be communicated to the local authorities concerned.

Appointments.

CARLILL, H., M.D. Cantab., M.R.C.P. Lond., has been appointed Assistant Physician to the Westminster Hospital.

KENNEDY, D., L.R.C.P. & S. Edin., L.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Newbury District of the county of Berks.

WACHER, H., M.B., B.C. Camb., one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 49, Ashford, &c., County Courts.

WARD, G. E. S., M.D. Lond., Assistant Physician to the Middlesex Hospital.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital.—Locum Female Surgeon.
Birmingham University.—Sen. Demonstrator of Anatomy. £250.
Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200.
Bristol General Hospital.—H.P. £175.
Bristol Royal Infirmary.—H.P. and H.S. £120.
Bristol University.—Demonstrator in Physiology.
Bury Infirmary.—Jun. H.S. £200.
Carlisle City, Maternity and Child Welfare.—Female Asst. M.O. £400.
Dudley, Guest Hospital.—Asst. H.S. £120.
Evelina Hospital for Children, Southwark, S.E.—H.P. and H.S. £160.
Great Yarmouth Hospital.—H.S. £200. Fifth-year Students. £150.
Guy's Hospital, S.E.—Two Clinical Assts. 1 guinea per session.
Hackney Union Infirmary, E.—Jun. Asst. M.O. £250.
Huddersfield County Borough.—Female Asst. M.O.H. £350.
London Temperance Hospital, N.W.—Surgical Registrar. 40 guineas.

Sunderland County Borough.—Asst. Female M.O.H. and Maternity and Child Welfare M.O. £400.
Walsall Education Committee.—L.T. Sch. Med. Insp. £400.
Walsall General Hospital.—Female H.S. and Anæs. £175.
Whipp's Cross War Hospital, Leytonstone, E.—Res. M.O. £1 per day.
Willesden Municipal Hospital, N.W.—Jun. Res. M.O. £300.

Births, Marriages, and Deaths.

BIRTHS.

HIGGINS.—On July 18th, at Straylea, New Milton, Hants, the wife of Captain F. B. Higgins, R.A.M.C., of a daughter.

HUGHES.—On July 18th, at "Coningsby," Stoke, near Rochester, to Dr. and Mrs. J. Morgan Hughes, a daughter (Joan).

SUCKLING.—On July 21st, at Charlton Lodge, Shepton Mallet, the wife of J. Jerome Suckling, M.B., B.S. Lond., of 5, Marine-terrace, Margate, of a daughter.

MARRIAGES.

CUNNINGTON—WEBB.—On July 20th, at St. Mary Abbott Church, Kensington, C. Willett Cunnington, M.B., Lieutenant, R.A.M.C. (temp.), of Tatchley House, Dollis Avenue, Church End, Finchley, N., to Phillis E. Webb, M.B., of 7, Scarsdale Villas, Kensington, W.

DRURY—TOMB.—On July 5th, at St. Gabriel's Church, Cricklewood, N.W., Major Kenneth Kirkpatrick Drury, M.C., R.A.M.C., to Meta Elizabeth, second daughter of William Tomb, Upperlands, co. Derry.

DYSON—GODDARD.—On July 13th, at the Parish Church, Wembley, Harold Edward Dyson, M.D. Lond., to Irene Eleanor, only daughter of Dr. and Mrs. C. E. Goddard, Harrowdene House, Wembley.

KINGSTON—VAUGHAN WALTON.—On July 15th, at Southsea, by special licence, Captain Stuart Hardy Kingston, R.A.M.C., to Mabelle Vaughan, third daughter of the late James Thomas Walton, of Bristol.

KYNGDON—DE LA COUR.—On July 11th, at St. Luke's, Oseney-crescent, N.W., Frederick Henry Kyngdon, M.D., of Lansdowne House, Tottenham, to Ethel Marian, elder daughter of G. F. de la Cour, M.D., and Mrs. de la Cour, of Camden-road, N.W.

MACAULAY—BRYSON.—On July 15th, at Dumfries, by the Rev. J. A. Campbell, Troqueer, Lieutenant Thomas Symington Macaulay, M.D., R.A.M.C., of Seremban, Federated Malay States, to Eleanor Minnie, daughter of Mr. Alexander Bryson, Castramont, Rotchell Park, Maxwelltown.

MUIR—LIVINGSTON.—On July 19th, at Inchbrook, Walkerton, Leslie, Major A. Ross Muir, R.A.M.C., T.F., to Ada Jane Buchan, daughter of James Livingston, Esq., J.P., Inchbrook, Walkerton, Leslie, Fife.

DEATHS.

ETTLES.—On July 19th, at his residence, 114A, Harley-street, London, W. 1, the result of a serious operation, William James McCulloch Ettles, M.D., F.R.C.S., in his 50th year.

STITT.—On July 17th, at Halifax, N.S., of blood poisoning, Robert R. Stitt, Medical Officer, S. S.——, second son of the late Colonel Samuel Stitt, of Birkenhead, and Mrs. Stitt, of Caldy, Cheshire, and loved husband of Eva Stitt, Port St. Mary, I.O.M., in his 51st year.

WEBB.—On July 16th, at Portballintrae, C. Walsham Webb, M.D.

WEDD.—On July 13th, killed in action, Captain Edward Parker Wallman Wedd, M.C., Yeomanry and R.A.M.C., aged 34.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE LANCET, VOL. I., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET completed with the issue of June 29th will be ready next week. Owing to the increasing shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a *post-card* (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge

EDITORIAL NOTICE.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

Notes, Short Comments, and Answers to Correspondents.

SHOCK IN BURNS AND SCALDS.

"TAKE care of shock and Nature will do the rest" summarises the teaching of the lecture delivered at the College of Ambulance (3 Vere-street, London, W.) on July 11th by Dr. J. M. H. MacLeod, physician for diseases of the skin at Charing Cross Hospital. The lecture was the ninth of a series on ambulance work and first-aid intended for medical practitioners as well as ambulance workers. Sir James Cantlie, who presided, spoke of the growing importance of burns and scalds, on account of the improved methods of dealing with which the St. John Ambulance Handbook had been recently completely revised. The lecturer referred to the increased number of accidents in factories due to war conditions, to the action in the war area itself of liquid fire, mustard gas, and the like, and to the terrible burns resulting from aeroplane accidents and air raids at home. Experience had already taught much. He described the differences between the injuries caused by dry heat and moist heat. As a rule burns were less extensive and deeper than scalds and nearly twice as fatal. The immediate gravity in either case depended more upon the extent of the surface injured than the depth of the injury. When one-half or even one-third of the body surface was injured death was almost absolutely certain. An arm or a hand might be burned to the sixth degree—i.e., totally destroyed—and yet with proper care the patient would recover. The duration of exposure to the heat was also an important factor. Burns of the first degree generally healed in a few days, those of the second degree in which blisters had formed were more difficult to deal with on account of the liability of the contained fluid to become septic. Treatment should be taken seriously, however slight the injury might appear at first sight. In 24 hours a blister might form, and blisters were peculiarly liable to become septic. Given a wound or a burn of the same area the lecturer would prefer the wound to treat. In burns of a minor degree the first thing to do was to soothe by bathing in a solution of bicarbonate of soda in the proportion of a drachm to a pint of water. After pain had been relieved it was important to avoid friction and give rest. A dressing with a bland powder such as stearate of zinc might be used, and it was not necessary to exclude air. In a burn of the second degree it was best to puncture and drain the blister after washing with 1:4000 $HgCl_2$ unless it was possible to ensure asepticity. The dressing should soothe and astringe; he had found a weak solution of aluminium acetate preferable to other applications. Picric acid was liable to irritate. No redressing was required unless the wound became septic, a condition revealed by a characteristic smell. To be taken off the dressing must be soaked, or growing tissue might be torn off with it. Of all injuries burns were most liable to be accompanied by severe nervous symptoms: hysterical manifestations in the case of small burns and collapse in burns of a large area. The first consideration should be the patient, not the burn. Put him into a bath at 100° F., clothes and all; leave him there as long as necessary; give a normal saline injection if desirable, but on no account a stimulant. Then cut the clothes off and put the patient to bed, remembering that the skin was hypersensitive and a hot-water bottle therefore out of place. The bed should rather be warmed before putting the patient in. For severe burns treated in hospital no dressing was required, but the part should be protected by a cage warmed by an electric lamp and the charred surface dusted over with a bland powder. Moderate sepsis was best left alone; if severe the patient should be placed in the bath again until the surface became clean. Little scarring occurred by this method, but it was important to place the injured part in a natural position in case contraction of the tissues should occur. A review of Dr. MacLeod's recent book on "Burns and Their Treatment" appeared in our issue of July 20th.

MEDICINE IN SPANISH.

Two standard medical text-books of moderate size have been done into Spanish under the editorship of Dr. Luis Felipe Calderon, professor of clinical medicine at Bogotá, and issued by Messrs. Henry Frowde, and Hodder and Stoughton, as Publicaciones Médicas de Oxford. They are (1) "Manual de Medicina," by Dr. A. S. Woodwark (pp. 415, price 12*s.* 6*d.*); and (2) "Emergencias en la Practica de la Medicina y de la Cirugia," by Mr. Percy Sargent and Dr. Alfred E. Russell (pp. 496, price 17*s.* 6*d.*). Spanish America is largely dependent on foreign medical literature and we are glad that British text-books should be represented. The books may also suggest an agreeable way to the medical student of picking up a modicum of a Spanish medical vocabulary.

CHILD-WELFARE LITERATURE.

THE National Baby Week Council, 27A, Cavendish-square, London, W., have published a series of pamphlets which should prove useful to workers in the cause of infant and child life conservation. *Nation's Wealth* (price 6*d.*) is a collection of "messages" from medical men and women, clerics, social workers, and others, pointing out the importance of child welfare work and containing useful ideas for speakers and lecturers. A sentence in the foreword by Dr. Eric Pritchard puts the case in a nutshell: "In the last analysis," he says, "the causes of infant mortality are want of knowledge and want of character, two wrongs that it is within human power to redress." This message is further emphasised in *Danger Ahead, or the Difficulties of a Young Mother*, a play in three acts, while the subject is developed with particular reference to the dangers of syphilis in the *Factors of Infant Mortality*, a lecture by Dr. C. W. Saleeby. *Baby Week, its Objects and its Future*, by Miss Alice Elliott; *National Baby Week from the Working-Class Mother's Point of View*, by Mrs. H. B. Irving; and *Civic Responsibilities with Regard to Child Welfare*, by Dr. H. Scurfield, are other lectures which deserve to be widely distributed and read. With the exception of the first mentioned publication the price in each case is 4*d.*

DISINFECTION OF PUBLIC VEHICLES IN CALCUTTA.

AT a recent meeting of the Calcutta municipal council the attention of the health department was directed to the report of Major Glen Liston, I.M.S., on the danger of infection from vermin in public vehicles, such as railway carriages and tramcars, and to the method of fumigation with hydrocyanic acid gas to get rid of the parasites. The council agreed to discuss the practicability of disinfection by this means with the Calcutta Tramways Company.

MORE MOULTING.

BETWEEN the issues of June 7th and June 14th the cover of the valuable weekly Public Health Reports, issued by the U.S. Public Health Service at Washington, turned from green to grey.

Dr. A. J. Rice-Oxley has been appointed justice of the peace for the County of London.

F. W. P.'s communication would have gained in value if the clinic to which he alludes had been described in detail. If this can be done it would be well not to obscure the issues by reflections on those responsible for the National Insurance Act.

Dr. J. L. Roux-Berger sends us a reprint of his paper in the *Presse Médicale* for May 30th, in which he dwells on the danger of late and incomplete operation in gunshot wounds of the pleura and lung. To leave an infected fracture of the rib or a retained fragment of clothing or projectile is to ensure the permanence of infections menacing the pleura. Early operation on the lines first recommended by P. Duval would avoid the chronic infections of the pleura and the pulmonary fistulæ which he has found always difficult to treat and liable to fatal complication.

Communications, Letters, &c., to the Editor have been received from—

B.—Baby Week Council, Sec. of; Sir J. W. Byers, Belfast; Major A. S. G. Bell, R.A.M.C.

C.—Dr. R. Craik, Lond.; Mr. B. Cridland, Wolverhampton; Dr. E. L. Collis, Lond.; Major W. A. Chapple, R.A.M.C.; Dr. J. B. Christopherson, Khartoum; Mr. W. G. Cooper, Chester; Surg.-G. F. Cobb, R.N.; Dr. A. S. Currie, Lond.

D.—Dr. B. Dunlop, Lond.

E.—Dr. G. Elliott, Toronto; Major R. Eager, R.A.M.C.

F.—Factories, Chief Inspector of, Lond.; Miss E. F. Ford, Lond; Capt. W. Fletcher, R.A.M.C.

G.—Dr. W. Gordon, Exeter; Dr. J. D. Grant, Lond.; Mr. J. Galsworthy, Lond.

H.—Messrs. J. L. Hatrick and Co., Lond.; Mr. J. N. Harris, Lond.; Major H. Hemsted, R.A.M.C.; Dr. C. M. Hough, Ambleside; Major A. F. Hurst, R.A.M.C.; Mr. C. A. Hill, Lond.

I.—Capt. A. C. Inman, R.A.M.C.

J.—Major-Gen. Sir Robert Jones, A.M.S.

K.—Dr. H. C. Kidd, Bromsgrove; Capt. E. B. Kitching, R.A.M.C.; Capt. E. B. Krumbhaar, M.R.C.; Messrs. P. S. King and Son, Lond.

L.—Staff-Surg. T. D. Luke, R.N.; London Hospital Medical College, Sec. of.

M.—Mr. C. Mayfield, Bristol; Sir J. W. Moore, Dublin; Dr. J. B. Mennell, Lond.; Mr. L. Morris, St. Albans; Mr. F. S. Miles, Hove; Mr. L. Mundy, Lond.; Dr. B. W. Martin, Leicester; Dr. J. A. Murray, Lond.; Dr. H. A. Macewen, Lond.; Mr. T. S. McCallum, Huddersfield; Messrs. Alex. Morison and Co., Edinburgh; Ministry of Food; Ministry of National Service.

Further Experiences IN COLONY TREATMENT AND AFTER-CARE.[1]

By P. C. VARRIER-JONES, M.A., M.R.C.S., L.R.C.P. LOND.,

FOUNDATION SCHOLAR, ST. JOHN'S COLLEGE, CAMBRIDGE; HONORARY MEDICAL OFFICER, CAMBRIDGESHIRE TUBERCULOSIS COLONY; AND ACTING TUBERCULOSIS OFFICER FOR THE COUNTY OF CAMBRIDGE;

AND

G. SIMS WOODHEAD, V.D., M.A., M.D., LL.D.,

BREVET COLONEL AND LIEUTENANT-COLONEL, R.A.M.C.; FELLOW OF TRINITY HALL, AND PROFESSOR OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE.

THE use of the word "cured" not being justified in connexion with any form of treatment yet brought to bear on tuberculosis, the term "arrest of the disease" has been substituted, though even this elastic expression has usually been superseded by still more guarded and tentative expressions.

The Cause of Relapse.

The arrest of the disease is said to take place only under certain ill-defined conditions. In the first place, treatment must be prolonged. That this may produce the desired result is quite in accord with pathological evidence. Moreover, from clinical evidence—from the general improvement in the condition of the patient, where we have the classical signs associated with want of activity of the disease in the lung, increase of weight and a normal range of temperature—it may be argued that if the treatment can be continued for a further period and improvement maintained, eventual arrest of the disease may be brought about.

In the case of the working man, however, no figures and no facts in support of this thesis can be adduced. Deductions from the experience gained in the treatment of the well-to-do are obviously open to many sources of error, for it has been demonstrated that well-to-do people who return to their former unsuitable, unmodified mode of life are in no way less liable to relapse than are their less fortunate brethren. The patients that do well are those diagnosed early, who have the sense and opportunity to carry on in their own home a modified form of sanatorium treatment—a well-regulated life without excesses of any kind, and in which the economic struggle is tempered to their conditions. Well-to-do patients who, either through their own fault or through the stress of circumstances, have to resume a strenuous existence amid surroundings not hygienically favourable are no less likely to relapse than is the working man. We have certainly no definite statistics to the contrary. Under these conditions, "once a consumptive, always a consumptive."

Sir Arthur Pearson lately said to his blind pupils: "The first thing you have to do is to learn to be blind." So, too, the consumptive must "learn to be a consumptive," so to readjust his life that the ravages of the disease may make slower progress; to avoid the things that lessen resistance; and, above all, to guard against excessive fatigue, worry, and mental strain. In other words, to live a sanatorium life. With our present knowledge we are, indeed, compelled to assume that except under the most favourable conditions complete arrest is out of the question except in a very small proportion of cases, and that the thing to be aimed at is a retardation of the disease such that a reasonable amount of work and exercise may be indulged in without exciting a recrudescence of those symptoms and conditions which oblige the patient to cease work.

The question thus resolves itself into—"Under what mode of life is the greatest retardation of the disease effected, for we know that no prolongation of the period of sanatorium treatment will so arrest the disease that a permanent cure is effected if the patient is again allowed to return to undesirable surroundings, or if in good home surroundings he resumes his old ways and habits in workshop and in office?" Dr. N. D. Bardswell's Midhurst figures give us information on this point. That all the Midhurst patients return to undesirable surroundings cannot be believed. Most of them were in that grade of society which lives in well-built, well-ventilated houses in the better-planned suburbs of our large towns and cities. Many worked in offices which, whilst perhaps not ideal, would not be condemned as wanting in light, air, or general sanitary amenity, and yet Dr. Bardswell's figures appear to demonstrate that the results obtained by the treatment of the middle classes at Midhurst were very little better than those obtained amongst working-class patients at Frimley. What is the cause of this universal (or almost universal) breakdown or relapse?

The Essential Factors.

As a temporary expedient sanatorium treatment gives excellent results. By itself, as a means of permanently restoring the patient to health, it has proved to be a failure. It is a good thing in itself, but not by itself. Something more is needed, and that something is what is now known as "After-care," designed to assist the patient in the continual struggle for fresh air, rest, and good food, the shoal on which the consumptive is shipwrecked, a struggle which accounts for the recrudescence of the disease and for the weakening of the protective forces essential for the final victory over infection. The less the economic struggle the slower the advance of the "arrested" disease remaining after a short course of sanatorium treatment. Bad surroundings are but a result of the economic struggle; without the struggle bad housing might be eliminated. Both must be swept away if the vicious circle is to be broken.

We see the results of the economic pressure, but cannot realise the fundamental principles on which any adequate system of after-care should be based. Build better houses by all means, but do not imagine that by building better houses, the sources of infection still remaining, much headway will be made in lessening the disease. A worthy squire in one of the eastern counties was so impressed with the importance of good housing as a factor in the struggle against tuberculosis that he erected a series of model cottages in his village. He is now pained and surprised to find that there is as much (if not more) tuberculosis in those cottages as in any other part of the county. One or two advanced cases were allowed to remain, with the inevitable result that the disease has spread; but then wages are no higher than elsewhere, and work, worry, and anxiety are as dominant as in other parts of the country. The struggle goes on, *massive* infection remaining ever ready to attack the depressed and claim fresh victims.

Two factors, then, are essential for the transmission of the disease from one member of the community to another. The one is complex, subtle, a force rather than a visible entity, but the results of that force are manifest every day—bad housing, insanitary dwellings, want of rest, want of food, anxiety, all already referred to, are the results of economic pressure, or, if we prefer the term, the struggle for existence. The other factor is material; we can see it, handle it, know it in a vague sort of way, test its properties—the tubercle bacillus, by which massive infection has been demonstrated. Build up resistance, and even massive infection may not prevail; lower the resistance, and less massive infection will suffice to set up the disease.

What means do we take to build up this resistance? We supply the ordinary dispensary patient with a little "cod-liver oil three times a day." A pious wish is expressed that the patient's windows will be kept open and "take all the fresh air you can and don't over-exert yourself." In a more progressive community preventive measures assume the form of the building of a few model cottages, which, however, are quickly filled with a mass of struggling humanity. The struggle to make ends meet, pay rent, and try to "carry on" continues—and the tuberculous cases are still allowed to remain—ignorance as to the preparation of meals, lack of time for rest and recreation, worry, anxiety are scarcely lessened. We have not raised the resistance even in a small degree.

The mere formation of an after-care committee will not afford any solution to a problem which must be attacked simultaneously from all sides by well-directed efforts, every one of which is to be welcomed, not only in respect to tuberculosis, but because the resistance of the race against all disease should be raised. Clear away slums, build garden cities, do all these things by all means, but at the same time make sure that other measures are adopted.

The Control of Massive Infection.

We must, above all, deal with one of the main sources of trouble, the "carrier of massive infection," for pathology

[1] THE LANCET, 1917, ii., 779.

teaches us, and with no uncertain voice, that though small doses of tuberculous virus *may* be harmless, large doses *must* be guarded against.

All are agreed that without infection by the tubercle bacillus there can be no tuberculosis. The usual argument that infection takes place in childhood and need not be taken into account in later life cannot, to-day, be discussed without impatience. Were there no specific bacillary infection, lowered resistance in adolescence would not induce tuberculosis, whatever other disease might manage to obtain a foothold. That we cannot in every case demonstrate the source of infection is no evidence that such infection may be overlooked or disregarded. Men and women are now going about their homes suffering from a disease which, either knowingly or otherwise, is labelled "bronchitis." Soldiers are granted recurrent sick leave on account of bronchitis, and 12 months later are found to be expectorating numbers of tubercle bacilli and *eventually are sent to a sanatorium for three months' treatment.* What an absurdity! The infective material is being expectorated in massive doses, but no means to prevent pulmonary infection are taken. We *could* keep the disease under control. Why have we not controlled it? Instead of going to the root of the trouble we have preferred to put on a patch here and a patch there, until we are obliged to condemn our own methods and are now seeking an excuse to "save our face." With regard to ex-soldiers, at any rate, we are now making no pretence that we select "early cases" for sanatorium treatment, and we are assured that unless cases are selected "early" the results will be eminently unsatisfactory; nor are we making the slightest effort to prevent the spread of infection, to deal with which adequately we must first determine the stage at which the consumptive is most infectious.

To the outer world, at any rate, the *bed-ridden* consumptive in charge of a village nurse is not, when adequate precautions are taken, a danger to the community. The real source of danger is the man who, just able to work, feels well on some days and rather bad on others; who struggles on with his work, often for long hours; who frequents crowded places, such as tramcars, buses, and eating-houses, and comes into contact with children and young people; is careless in habits and manners, coughs a good deal and carelessly, and is said to be suffering from "bronchitis"; the "early case" returned from the sanatorium, or an out-patient at one of our great hospitals. Our sanatoria are not available for these cases; nor are the few homes for the dying willing to receive them—they are probably such a long way from death—and they will not go to the poor-house infirmary.

The Function of the Dispensary.

Most of the consumptives now with us are "advanced cases." They flock to our new dispensaries, and the extensive statistics compiled from the records of the visits of these poor unfortunates are accepted as evidence of splendid things achieved. The higher the figures the more proud are we of the results of our labours; indeed, the efficiency of the tuberculosis officer is judged by the number of clients attending his dispensary—unfortunates, "out of works," the unemployable—a burden to the insurance committees, a trouble to councils and guardians. It is the proud boast of some dispensaries that the number of patients "seen" in a morning amounts to a grand total of 200. Are these 200 there to be cured by means of tuberculin, or cod liver oil, or otherwise? Are they instructed as to the mode of life they should lead? If so, the instruction must be delivered at a very brisk rate, and with scanty respect to detail as to how it is to be put into practice. Many of these patients are sources of infection, but little or no adequate attempt is made to protect the community from the danger to which they are exposed from their presence.

Instead of taking pride that we see 200 in a morning, should it not rather be counted to the dispensary doctor for righteousness that, examining but few patients, he deals with them thoroughly, and then in the interests of the community asks that he may give the unfortunate consumptive an opportunity to live a reasonable life, to do his 50 per cent. or 30 per cent. of work under conditions in which the danger of infecting others is absent or reduced to a minimum.

Sir Robert Philip's well-thought-out scheme is being distorted and turned to very wrong uses. The dispensary—perhaps an unfortunate term under the circumstances—was designed as a centre of activities in a well-defined scheme, but the very keystone of the situation is often turned into a mere adjunct—an out-patient department with none of the special advantages of a large hospital. Here the "material" cannot be used for teaching purposes, for obviously few dispensaries can be attached to medical schools, though were these dispensaries "run" properly they might, in large towns at any rate, become centres at which post-graduate courses of lectures and demonstrations could be given to the general practitioner of the neighbourhood.

The Problem of the Chronic Case.

In the meantime how are we to deal adequately with the mass of infection left untouched by our present dispensary or sanatorium organisation? Most of the patients who spread infection are those for whom there seems to be no niche into which they can be fitted. "Chronic case," says the physician, and as a "chronic case" it is dismissed. But it is this chronic case which day by day obtrudes itself upon our notice. It is this type of patient who steadily descends the social ladder, pulling his family down with him. Did this affect the patient himself, merely, the matter would not be so urgent. The whole family, however, may be brought to the verge of poverty—to abject misery; this quite apart from the risk of infection to which reference has been made, and the problem comes to be of importance from the social point of view. An acute illness of short duration, followed by the death of the bread-winner of the family, is borne comparatively easily. It is the long-drawn-out illness of that bread-winner, with increasing poverty extending over many years, that brings such havoc in its train.

At present we place a premium on infection, in so far as many of our benevolent after-care societies aim merely at the provision of sufficient help to keep the patient out of the workhouse infirmary. Far better that such help should cease and the man be taken into the infirmary and cared for and the infection circumscribed; better still that he be given the opportunity to recover some of his powers of resistance, receiving a sufficiency of food, living in the open, and, under supervision, working part of the day; for with the risk of infection effectually controlled at the source he is no longer a danger centre, especially if the family, also placed in favourable surroundings, have their resistance strengthened and their minds set at rest by the assurance of remunerative employment.

Is it a practical proposition, then, to give to a large number of consumptives the opportunity to carry on their usual or other avocation under conditions carefully controlled by a medical man? It is said that the problem is too vast, the expenditure too great, the immediate prospect of success too visionary. Is this the case?

The Tuberculous Ex-soldier.

It is certainly useless to spend money on treatment which neither cures the patients nor prevents infection of others, but we are justified in doing the best we can for tuberculous soldiers discharged from the Army if there is any prospect of prolonging their lives and protecting their families. Health, even life, has been sacrificed by these men, though the glory of sacrifice is wanting. Theirs is not the honour of dying facing the foe, of being wounded in battle, of losing an eye or a limb, of receiving a visible mark of conflict. Nevertheless, our sympathy and help can never repay the sacrifice made by the man who is wounded no less surely, and no less severely, though by an invisible foe—the man struck down by, and hopelessly invalided through, consumption, often, as we now know from wide experience, neglected and allowed to die a lingering death, through an agony prolonged perhaps for years. There is no lack either of sympathy or of money; neither is it for want of appreciation that the man is neglected—rather is it want of courage, lack of initiative, of imagination, that what at first sight appears to be a hopeless problem is allowed to drift on from month to month, from year to year.

It is argued that consumption is incurable. The physician is most emphatic that the best remedy is prolonged sanatorium treatment, and that, however prolonged, sanatorium treatment must be followed up by "after-care"—a phrase as elastic as it is vague.

Why, then, is sanatorium treatment not prolonged if by its means the "cure" may be made more certain, if lack of accommodation can be no answer nor lack of funds? It is a

problem of "human nature." Few ex-soldiers can be expected to consent to a prolonged course of sanatorium treatment under existing conditions. Has it ever occurred to us to ask the reason for this? Which among us would be content to do useless labour the year round? As one intelligent patient remarked: "We waste time; we wish to learn something, we have nothing to occupy our minds, we want to improve ourselves; you say that we cannot go back to our original trades, yet you do not attempt to provide us with a substitute; we cannot dig, to beg we are ashamed. If we cannot exert our bodies, can we educate our minds?" "Yes," it may be said, "but this was an exceptional patient! Are you going to educate your farm labourer, your van driver, your crossing-sweeper?" Yes. Our object is so to educate the man that he may realise that an intelligent application of what he is taught of his own trade will enable him to carry it on under favourable conditions and surroundings, and it must be our business to see that these surroundings are forthcoming.

To hold that we are at the moment unable to call into existence these circumstances is to beg the question. If it is a question of money, we spend £7,000,000 a day on destruction; a fraction of that sum, properly expended, would soon call the required conditions into existence.

Most of our ex-soldiers are intelligent, keen-brained workers. Two distinguished visitors who came to inspect the colony recently remarked that the patients seemed to be an extremely intelligent set of men, and that there could surely be no difficulty in teaching them a new trade. They were astonished to learn that the patients in question were a window-cleaner, a lodging-house cook, a common sailor, a theatrical scene-shifter, a jobbing tailor, and a plough-boy (this plough-boy showed such aptitude at carpentry that he is now, after six months' training at the colony, earning his living with a firm of carpenters in a large country village).

The patients, given no opportunity to show their intelligence, cannot be blamed if they evince no initiative or desire to start a new trade. If anyone of us were suddenly told—having spent any capital we may have possessed—to start on a new and unaccustomed line, should we not have one or two sleepless nights? And presumably we have been trained somewhat more thoroughly than has the window cleaner or the lodging-house cook.

How frequently we blame the working man when we should blame ourselves for want of imagination and lack of sympathy and foresight! We prescribe a treatment which without our help, often withdrawn at the critical moment, it is impossible for the patient to carry out.

Are we, then, to extend the treatment and our help for "a lifetime"? As far as our present knowledge goes we say, and unhesitatingly, Yes!—not only for the patient's sake, but still more for the sake of those with whom he comes in contact.

Prevention is better than cure, but if the two can be combined we are placed in a position to solve a very difficult problem and to do a really great work. Can the two questions be so linked that one set of machinery may be made to "control" both?

The Provision of Useful Employment.

Directors of sanatoriums find that ex-soldier patients discharge themselves even before the end of the regulation three months. Are there any reasons for this beyond those mentioned above? There are, and they are usually well founded.

1. The temperament of the patient is such that he cannot accommodate himself to institutional life. Such patients are not numerous, but are found in all institutions, and obviously it often becomes a question of the suitability or unsuitability of the patient for the particular type of institution in which he is placed.

2. Patients sometimes discharge themselves owing to domestic or home difficulties. This is generally considered by the medical superintendent as an excuse rather than as a reason, often before investigation is made into the real state of affairs of the man concerned. Can we expect a man who feels fairly well and able to do a certain amount of useful work to grind away for months at monotonous tasks, especially when he knows that his family is on the verge of starvation, or, at any rate, is in worse circumstances than if he were at home and could resume work at his own trade.

Here is the obvious remedy. Let the patient, instructed in a trade which if not his own is closely allied to it, realise that whilst undergoing his treatment he is being trained for a better berth, a more highly remunerative job.

It is the "waste of time" which the patient imagines is going on during his stay at the sanatorium to which he so strongly objects. For the ex-soldier the question of income is of little account, for his family allowances are good and in many cases are equal to the man's pre-war earnings. Still, without stimulus to the brain, with his muscular energy going to "seed" doing monotonous or useless work, a condition of mental discontent, easy to understand but difficult to overcome, seizes the patient, who "does his time" and longs for home.

Experience gained at the Bourn Colony and at Papworth Hall goes far to show that the mental attitude of the patient is materially improved by useful occupation, the nearer to his own trade the better, whilst it is found that with time and care, which assuredly are never wasted, there is no insuperable difficulty in grading any kind of work as may be desired.

What objection is there to a cabinet-maker following his own trade at a sanatorium? Difficulty in supervision? This, in the experience of the colony, amounts to nil. Not sufficient exercise? What, after all, are we attempting? Certainly not to turn a cabinet-maker into a navvy. Quarrying, indeed, is exercise, but it is not essential to the restoration of our cabinet-maker to health. Ours, fortunately, should not be a difficult task; it is to convince the cabinet-maker that he can follow his own trade in the environment of the colony. Make those conditions as favourable but as simple as possible, so that when your patient returns home he may "carry on" under the same conditions. Demonstrate to him that cabinet-making need not of necessity be carried on in a superheated atmosphere—that, at any rate, we have proved; also that lens-mounting and testing in scientific instruments may be carried out without a dark room! The ingenuity of the patients under treatment, properly directed, has already been responsible for the invention and construction of devices and apparatus which enable these men to carry on their occupations under good hygienic conditions.

The combination of sanatorium treatment (perhaps the term "colony treatment" is to be preferred) and industrial work is surely a step in the right direction. We have admitted that there is no "cure" for tuberculosis, and that the best results obtainable are a return to work and a prolongation of life, which may be very extended. If we can bring about the arrest of the disease whilst the patient is carrying on his own trade, have we not solved, partially at any rate, the problem which we set out to solve? Is it necessary that our cabinet-maker should return to an unhealthy workshop to struggle against a bad environment and work at a pressure which will mean a further breakdown? Having determined the conditions under which a cabinet-maker should live and work (we are now dealing with the ex-soldier enjoying a pension), he may obtain those conditions on the colony estate, with the inestimable advantage that his pension will be continued so long as he continues in residence and does part-time work, receiving a fair wage, doing work accurately graded to his strength—no more and no less—and surrounded by a social atmosphere in which he feels that he is a useful and satisfactory member of the community; the State in the meanwhile having the positive assurance that the bacilli which are coughed up by our patient as he goes about are rendered harmless and that the man is thus no longer a danger to his fellows.

The Colony at Papworth.

"The scheme sounds all very well in theory, but have you put it into practice?" Yes; on the colony estate at Papworth are at the present time families whose bread-winners are consumptives, with tubercle bacilli in their sputum, who by means of the State subsidy—a pension—are carrying on their original trade under ideal conditions—happy, contented, and earning their own livings. A concrete proposition has been placed before these men, and they have not hesitated to grasp it and avail themselves of what is its best feature—the shielding of the patient from the keen competition of the outside world.

"All this deals with a mere drop in the ocean! What practical result will be obtained?" Surely, it indicates a means of humane segregation—not making men inmates of an institution merely, but free men in a free English village. What can be done in one district should be possible in others. Progress may be slow at the outset, but once started on right lines may we not expect an increasing momentum?

To what can the success of the experiment be attributed (for that it has been a success we are now convinced)? To several factors, but undoubtedly the chief of these is the payment of the soldier's pension, a State subsidy.

At no previous time has there presented itself such an opportunity of subsidising carefully controlled and graduated labour—a control at once complete, humane, and sympathetic. The elimination of all harshness or scrimping is essential; the patient must be kept well away from the poverty line. A pension continued even for a number of years is a small price to pay for the doing away with infection even of a single individual, but from this cost must be taken the return in life and work, which is ample. But not only are the immediate members of the man's family protected, but his fellow workmen, his old acquaintances at the public-house, his fellow travellers in train, tramcar, and bus—all benefit from the removal of this single source of infection. And what of the patient himself? He enjoys a four- or a six-hour working day; his leisure hours are spent in a garden, his own, planted with his own hands, with which also the fruits of his labour are gathered in; he enjoys the entertainments given at the colony from time to time, and with a library placed at his disposal his mind is kept active, and also by the stimulus of popular and entertaining lectures.

A Hopeful Outlook.

What patient with these advantages would, if matters were explained to him, return to a crowded street, struggle on working 10 hours a day, gradually break down and be left to the tender mercies of the relieving officer? The social life of the colony, though touched upon incidentally only, is a vital part of the scheme, and must on no account be neglected. A patient used to town life cannot be expected to leave all its attractions and banish himself to the country unless he may look forward to some compensating advantages. Make an attractive proposition to him, and offer him a life worth living, and the community will receive—in value commensurate with the degree of infection removed—a full return for its outlay.

We are aware that we are limning a bright and pleasing picture, and it may be objected that the number of patients already dealt with is so small that such a picture is overdrawn, and further that it is impossible to generalise from so few special cases; but we may remind our readers that the idea of even one patient subjecting himself to the colony treatment has often been scouted, but the one came, and if one, we argued, why not two, if two why not more, and we were not wrong. Difficulties there were and will be—that of removing objections was admittedly great, but now with the experience gained there appears to be no reason why all or many should not be persuaded to come. As a matter of fact the applications for houses on the estate are at the moment more numerous than are the houses at the disposal of the committee.

It often happens, when it is first suggested to a resident patient that it would be well for him to bring his family on to the estate and work there, that he will not listen to the proposition, or he makes demands and conditions that it is impossible to meet. He tries to work at home but breaks down. Then it is that he is willing to bring his family with him and return to conditions which he finds were sound and under which he had a few months previously regained so large a measure of health and strength. He has learned his lesson in the hard school of experience; our advice is recalled and conviction is followed by action. The man is ready to make a sacrifice and we are ready to render that sacrifice as slight as possible. We place before him a concrete proposition ensuring work under favourable conditions for a number of years, this number now depending upon the funds available for the purchase of land and for the building of houses, and usually our terms are accepted.

We now know that there will be no lack of applicants for the houses on the estate. The non-infectious and the more able-bodied will not remain longer in the colony than is necessary to establish their health and working capacity. The chronic cases with numbers of bacilli in the sputum, patients who have no friends but who have a 50 per cent. working capacity when working under ideal conditions—we shall continue to welcome. They are the despair of the general practitioner and of the physician to the out-patient department, but there is no difficulty after gathering them in, in helping them. Their labour cannot be fully remunerative, it is not expected to "pay," but with their "subsidy" there will be no great loss, certainly no greater loss to the State in the long run than at present. Any deficit is the price the State must pay for the elimination of centres of infection, without which all the benefits of our building schemes will be neutralised and our good intentions brought to naught. By all means house the working classes properly—that is a far-sighted policy; but keep the new houses free from infection.

Outline of the Scheme.

It may be objected that a coöperative system such as that now suggested is far removed from the activities of an institution. This may be true, but the scheme of the colony is essentially more comprehensive than that of the sanatorium. On the one hand, it reaches towards an intelligent after-care movement, and on the other it is wide enough to provide hospital accommodation for a patient resident in a cottage who has a serious breakdown—and even under the most favourable conditions this is inevitable—and the hospital after all is the centre of the activities of the community as far as the restoration to health of its inhabitants is concerned, though the colony scheme embraces all the essentials of the ideal system which is the aim of "after-care" committees to establish.

It comprises hygienic housing conditions, abundant light and air, an efficient nursing staff available from the central institution—a staff known and trusted, friends rather than officials; a garden, the ideal exercise ground, combining that privacy and feeling of ownership so dear to the heart of an Englishman; and workshops, the property of the colony, where the work is strictly regulated according to the patient's health and strength. In some cases the work is done "at home" in a room or building specially adapted for the purpose, where the patient may learn to live the life that is best suited to his special condition. The income earned by the patient at his trade is, with the pension earned as a soldier, sufficient for his needs, but the necessary incentive to do more and better work is never wanting, for although the amount of the pension remains the same the wage earned depends on the skill and assiduity of the patient and the number of hours during which he can train himself to work.

It has been hinted that the colony is admirably suited to the development of slackers—an idlers' paradise. A consumptive patient with numerous tubercle bacilli in the sputum can never be set down as a slacker. He is definitely diseased. There can be no question of malingering. The proof of the presence of the disease can be demonstrated. The oft-repeated mistake of accusing the consumptive of slackness is a sure road to disaster. With all the good will in the world he is unable to do a full day's work. It must not be expected of him. Once the presence of the bacillus is ascertained and the diagnosis established the greatest caution must be exercised in dealing with so-called slackness, for be it remembered that the consumptive is a strange psychological phenomenon, and as a rule is ready to do more work than is good for him rather than too little. This is not the experience of all officers of sanatoria, but we believe that the explanation is that the work given is monotonous and irksome, and often not well adapted to the man's temperament. Here we assume that the man is working at his own trade or one nearly allied to it, that he is earning some money by it and is looking forward to earning more, and it is our experience—now not a negligible quantity—that the patient far from slacking takes pride in showing how well he can do his work. The more advanced the disease—within, of course, well-defined limits—the more anxious is he to "carry on." The exceptions, few in number, have to be dealt with specially.

The Colony a Complete Scheme.

As yet it is scarcely realised that the colony, hospital and settlement constitute a complete scheme to deal with tuberculous cases of all kinds. Here is no picking or choosing of the type of case to be treated. Some critics object that the work is not strictly limited to the so-called early cases, whilst others, especially corporate bodies, appear to think that the colony should be filled with cases practically hopeless from the beginning, and with these only.

We have given our reasons for following a line laid down at a very early stage of our work, and we are convinced that any departure from this line would interfere most seriously

with the working of the scheme as a whole. If, on the one hand, any but curable cases are refused admittance, the most dangerous and pitiful cases are left at large to injure others and to suffer alone; whilst if nothing but advanced cases are admitted the colony at once becomes a hospital—nursing staff, hospital accommodation, expenses all increasing out of proportion to the good effected—and the colony, instead of taking its place in a well-rounded scheme, becomes a hospital for incurables, a home for the hopeless, and a place to be avoided by the hopeful, with the great moral elements of hope and encouragement essential to success for the treatment of all tuberculous patients completely eliminated.

Naturally, it is a source of intense satisfaction to us that the £75,000 voted by the British Red Cross Society to her sister society in France is being devoted by that society to the provision of a colony for the treatment and training of tuberculous soldiers—a colony to be laid down and administered on similar lines to those on which the Papworth Colony is run.

COLONIES FOR CONSUMPTIVES.

BY NOEL DEAN BARDSWELL, M.V.O., M.D. EDIN., F.R.C.P. LOND.,

LATE MEDICAL SUPERINTENDENT, KING EDWARD VII. SANATORIUM; MEDICAL ADVISER TO INSURANCE COMMITTEE FOR COUNTY OF LONDON.

BROADLY speaking, there are two alternative policies relative to the treatment of the consumptive worker: either the patient must be kept at an institution until he is cured and can return with reasonable confidence to his former life and employment—this may be a matter of years—or, following a shorter course of sanatorium treatment, we must so change his environment as to render his conditions at home and at work such that recovery from tuberculosis is possible. It is the realisation of these facts that has led to the evolution of after-care organisations and, more recently, to the conception of colonies for consumptives.

The Two Types of Consumptive Colony.

The term "colony" is used to describe two types of institutions. These two colony schemes, though having much in common, present certain distinctive features which sharply differentiate the one from the other.

Scheme 1, associated with the name of Sir Robert Philip, provides for an institution for the exclusive reception of the early and most curable cases, with a view to giving them prolonged treatment and a training in some agricultural employment. Though linked up with the sanatorium from which the colonists are drawn and with the other elements of a comprehensive anti-tuberculosis administration, it is designed as a separate institution. Equipped upon simpler lines than a sanatorium, it is less costly to administer. Moreover, the patients, by performing useful work in the institution and in the grounds, gardens, and farm, are able to reduce somewhat the cost of their maintenance. To give the favourable case some 12 or 18 months' institutional treatment in place of the more usual period of three to four months should, apart from any question of re-education, appreciably improve his outlook. The patient returns home, having made substantial progress on the road to recovery. With some after-care he may be expected, in many instances, to attempt successfully a return to his ordinary life and employment.

Scheme 2 is more comprehensive in scope, in that it makes provision for all kinds of cases, irrespective of the extent and character of their disease. Thus it comprises, under the same administration, a sanatorium, a colony as in Scheme 1 for vocational training, and a home for advanced cases. The opportunity for occupation and vocational training, however, is not limited to the most favourable cases, but is offered to every patient who desires it and who has a prospect of some degree of restoration of working capacity. Further, recognising that many patients can never be so restored to health as to be able to hold their own in the open labour market, the colony seeks to establish suitable trades and industries which, by offering remunerative employment under favourable conditions, will not only give scope for re-education, but encourage the permanent settlement in the neighbourhood of the colony of ex-patients and their families, thus forming the nucleus of a community living under the healthy conditions of a garden city. It is hoped that by this means the voluntary segregation of the consumptive will gradually be achieved.

This type of colony owes its inception to Professor Sims Woodhead and Dr. P. C. Varrier-Jones, and it is upon these principles, just briefly outlined, that the Settlement at Papworth is now being developed, under the care of these two pioneer workers. The experiment of Papworth cannot fail to be most instructive. Should it prove that the setting up of industries for the employment of consumptives is a practical proposition, a vista of great possibilities will be opened up.

Experience of Sanatoriums in the Colony Principle.

Hitherto, for lack of money, neither prolonged treatment nor re-education has been possible except on a modest scale. What these measures might effect if adopted systematically is therefore, to some extent, a matter of speculation. However, many sanatoriums present striking examples of the efficacy of suitable employment under favourable conditions among their personnel. To name two institutions—at Peppard Common over 50 per cent., and at Nayland 70 per cent., of the staff are made up of former patients. These individuals are all earning their livelihoods. Some are on the permanent staff, to all appearances cured, others will remain for a year or two, then to return to the outside world; others again will remain indefinitely, performing work within their capacity, partially disabled for all time, but still useful members of society.

Similarly, after-care organisations furnish many instances of the maintenance of health and capacity for work by consumptives for whom healthy and sufficiently remunerative employment has been secured. That the principles underlying the colony idea are sound need not be insisted upon it is rather a question as to how far they can be put into practice on a large scale.

Experience of Existing Colonies.

As yet colonies in the country are too recently established to provide data of much value. None the less, the experience of a few institutions is sufficient to give some idea of the probable usefulness of colonies, and of the lines upon which these institutions may best be promoted.

The Edinburgh Colony.—The Springfield Colony, near Edinburgh, was organised by Sir R. Philip and opened in 1910.

The colony consists of a mansion house and 30 acres of land, comprising two acres of fruit and vegetable garden, a poultry farm, pig-rearing department, and a mixed farm of 12 acres. There is accommodation for 25 patients, who under the direction of the resident staff, assist in the various activities of the colony.

Data kindly given me by Sir R. Philip relative to the period 1910 to 1914 show that during these years 88 patients transferred from the associated sanatorium passed through the colony, the average length of stay being some 12 months. Of this number, 11 on their discharge changed their employment for work other than on the land. Nine returned to their former occupation, 20 returned to work on or in connexion with the land, mostly in the colonies, 2 were taken on to the colony staff, and 5 female patients emigrated, domestic service seemingly being the occupation usually followed. The remaining patients returned home but to no stated occupation.

The condition of these 88 patients in 1917, exclusive of 4 who had been dismissed from the colony and 6 who have been lost sight of, was as follows: Well and in full work, 44; in poor health, 4; died of injuries or disease contracted on active service, 3; died of tuberculosis, 25; died, cause not stated, 2.

The Leicester Colony.—The experiments in this colony, carried out under the direction of Dr. Killick Millard, medical officer of health of the city of Leicester, date from 1914.

The 1914 scheme consisted in the placing during the summer months of a small number of convalescent sanatorium patients upon a large nursery in Derbyshire, practically a summer camp. Though on a small scale, the experiment was a success. The patients all benefited greatly, and allowing for the income they earned by their work on the nurseries the cost of their maintenance worked out at approximately 11*s.* a week.

By the 1916 and 1917 schemes convalescent male patients were employed under a skilled gardener in a large fruit and vegetable garden within easy access of the sanatorium. Though living within the sanatorium precincts, the colonists, limited in number to 20, were accommodated in a separate pavilion and followed a different routine from that of the patients in the main sanatorium. In particular

they enjoyed the privilege of being allowed to go home at week-ends. The average stay at the colony worked out at three months. It was found difficult to persuade the most suitable of the sanatorium patients—namely, the able-bodied, to enter and remain in the colony, the men preferring to return to work at which they could earn a high wage. Clinically the results were most satisfactory. Financially, the cost of maintaining the patients in the colony department was the same as the weekly cost ruling in a sanatorium, the return from the colonists' work being sufficient approximately to pay the wages of the skilled instructor.

Nayland Sanatorium and Colony.—At this institution, conducted by Dr. Jane Walker, a good deal of pioneer work upon colony lines has been carried out during the 16 years of its existence.

Although essentially a sanatorium, the work at Nayland has always been governed by the desire to promote the interests of the patient after his discharge from the sanatorium. As previously stated, every available post on the staff is filled by an ex-patient. Some of these former patients thus employed in the institution live in a hostel some distance from the sanatorium, and form the nucleus of a settlement. With regard to employment and vocational training, apart from instruction in gardening and vegetable growing no attempt is made to give an agricultural training. However, the sanatorium possesses a mixed farm of 200 acres, should the future see any demand for a training for the land. Considerable attention has been devoted to handicraft. At the present time there is provision for instruction in carpentry, toy-making, and boot-repairing for men, and for dressmaking and embroidery for women. These facilities are open to all the patients. Another feature which has a distinct value as an education is the sanatorium shop run on the lines of a village store. Here patients can learn the management of a small village business. More definitely upon colony lines is the dressmaking shop in the neighbouring village of Nayland staffed by four former sanatorium patients, and the school of high-grade metal craft recently established in the same village. This latter technical training colony is accommodated in picturesque premises, equipped with admirably fitted workrooms, formerly a leather factory. It accommodates 25 patients, who will be taught an interesting and remunerative trade. Certainty of employment is assured to the proficient by the Artificers' Guild, with which this enterprise is closely identified. Mention also should be made of the department for the treatment and education of tuberculous children, which forms another interesting feature of Dr. Walker's establishment.

The Papworth Colony, near Cambridge.—The Papworth Colony, directed by Dr. Varrier-Jones, is a development of the earlier enterprise carried out at Bourn. Its characteristic features have already been referred to.

The colony comprises a large mansion, with grounds of 16 acres, which include a large walled-in kitchen garden and orchard, and 100 acres of agricultural land. The mansion is devoted to administrative purposes and to the accommodation of advanced cases. Accommodation for the more favourable cases is furnished by shelters built in the grounds. To provide means of useful employment for the patients, a carpenter's shop, forge, and mechanical workshops are in course of construction. Already the carpenter's department is well developed, and is in a position to execute orders for open-air shelters and other portable wooden structures. This department is managed by an ex-patient, a skilled carpenter, and is run on business lines; the actual work is carried out entirely by the patients. The making of parts for the Cambridge Scientific Instrument Company is another enterprise which has passed the experimental stage. Opportunity for the employment of some women patients is supplied by a neighbouring fruit and jam-making industry. The gardens and land offer an agricultural training to those who elect for it. With a view to the permanent settlement of ex-patients the colony has acquired some model cottages formerly occupied by employees on the estate; the erection of further cottages will be the work of the patients. Already applications by former patients for cottages exceed the available accommodation.

The Kinson Colony, Bournemouth.—This colony, under the management of the Y.M.C.A., is a unique experiment in that it offers facilities for a complete training extending over a period of at least 12 months in small-holding management and intensive culture.

Admission is limited strictly to fully convalescent patients who, while resident in a sanatorium, have proved themselves equal to at least six hours' manual work daily. There is accommodation for 21 colonists. The work is directed by an honorary resident superintendent, a gentleman of long experience of farming. Dr. E. H. Greves, of Bournemouth, acts as honorary visiting physician. Some difficulty has been experienced in obtaining the full complement of 21 colonists; the length of the training required and the uncertainty of employment subsequently would appear to be the chief deterrents. Further, the physical standard required of candidates is a high one and excludes many would-be colonists.

The Hairmyres Colony, Lanarkshire, N.B.—Though not yet fully organised, the Hairmyres Colony demands notice, since it is the most ambitious scheme yet projected.

The colony is intended for the after-treatment and training in an outdoor occupation of favourable cases and for the treatment and education of children. The colony, situated within easy access of Glasgow, extends to 200 acres. The buildings, which are well advanced in construction, will accommodate approximately 50 men, 50 women, and 50 children. A model farm and the best possible equipment for training in poultry-keeping, fruit and vegetable growing—in short, all kinds of agriculture and horticulture—are being provided. A noticeable feature is the Associated School of Forestry, at which suitable patients will receive a thorough training in theoretical and practical forestry. Each department of the colonists' activities will be in charge of a skilled foreman. Dr. A. H. McPherson, under whose care the colony is developing, will be responsible for its general direction.

Space will not permit of reference to other colony undertakings.

The Financial Aspect of Colonies.

Running expenses.—It has been shown that an institution for convalescent patients can be run at a lower cost per head than a sanatorium. Simple accommodation and equipment and quite a small staff are sufficient; moreover, the labour of the colonists can contribute considerably to the running and upkeep of the establishment. Apart from thus reducing current expenses, it has not been demonstrated that patients by their work can add appreciably to the income of the colony, much less render the institution self-supporting. At the Edinburgh Colony the cost per head of 20 patients for the year 1915–16 worked out at 22*s.* a week. At Coppings Green Market Garden Colony, managed by Dr. J. E. Chapman, in 1906, the cost per bed per week of 25 patients was 21*s.* Under peace conditions the cost of maintenance per head at a colony should not exceed approximately 20*s.*, and might well be a lower sum. That efficient treatment can be given at a low cost has been proved conclusively.

Capital cost.—The capital cost of colony schemes varies enormously, depending upon their scope.

The Hairmyres scheme has been budgeted for at some £100,000. The Edinburgh Colony cost approximately £4000 to establish. The cost of the proposed colony at Hull is estimated at £10,000, inclusive of the purchase of freehold, adaptation, equipment, and endowment; the colony will accommodate at least 35 patients. In respect to purchase, a capacious house, two cottages, buildings, and other out-offices, with 29 acres of land, valued at £3750, have been purchased by Sir James Reckitt and placed at the disposal of the Hull Tuberculosis After-care Committee, with option to purchase at any time for the sum of £2000.

The capital cost of the original colony at Bourn for 15 patients was a rental of £20 a year for the main building and 10 acres of land and £400 for alterations and additional buildings. The Coppings Green Colony for 25 patients was established on a similar economical basis, the rent of the buildings and 10 acres of land having been £20 per annum, and the cost of alterations and equipment having been covered by an outlay of £400. The Y.M.C.A. Colony for 21 patients, complete with buildings, including farm buildings, equipment, and 30 acres of freehold land, cost £4000.

At Nayland the premises which comprise the colony for technical training are rented for £80 a year, and the sum of £300 has covered the cost of equipment. The instructor receives a salary of 90*s.* a week.

At this moment, when labour and material are scarcely to be obtained, the most economical method of establishing a colony is by renting and adapting suitable premises, as has been done at Bourn and Nayland.

Experience shows that a colony can be run with equal success as a distinct institution or as a department of an existing sanatorium. A colony on the Papworth principle could be built up round the nucleus of a sanatorium. A distinct advantage in grafting a colony on to an existing institution is that thereby an experienced medical staff is immediately available, and that various essentials, such as light, drainage, power, water, transport, &c., are already provided for. It is necessary that the work of the patients,

whether on the land or in workshops, be directed by whole-time skilled officers, since the medical superintendent is too occupied to spare the time for teaching, even should he possess the requisite knowledge.

The Probable Rôle of the Colony.

It is the general experience that few things are more difficult than satisfactorily to change a consumptive patient's occupation. Light employment requiring little training is usually ill-paid, and in consequence unsuited to anyone with dependants. For the more skilled trades, which command a good wage, long training and experience are necessary. It can readily be understood, then, how that the most successful efforts of after-care organisation have been associated with the principle of enabling the patient to follow his usual occupation, or something akin to it, under reasonably healthy conditions.

Hitherto the training given to patients in a sanatorium has been valuable, chiefly as providing an interest, and thus relieving the monotony of a somewhat stereotyped routine. Comparatively rarely has a patient been enabled to earn his livelihood in a new calling learnt at the sanatorium. In the past most success has followed the training of patients as chauffeurs, but in future this avenue of employment seems likely to be closed.

It seems probable, therefore, that colonies will achieve more in virtue of the prolonged treatment they will give than as the result of their facilities for vocational training. So far as the civilian is concerned, vocational training cannot meet with any great measure of success unless it be accompanied by the provision of employment for those trained. This truth is reflected in the suggestion of sanatorium workshops and factories in connexion with certain trades which would permit of consumptive employees following their usual occupation under favourable conditions.

With regard to agriculture, it is the general experience that farming operations are too skilled and too arduous to be suited to many patients, although they are admirably adapted to the treatment of the more robust; moreover, few individuals born and bred in a town take kindly to a rural life. Except in the case of institutions serving rural areas, more may be expected from handicrafts than from agriculture in the way of re-education. Every institution, however, should be able to give the townsman some practical knowledge of kitchen gardening and allotment culture.

Financial Aspect of Colonies from Standpoint of Patient.

Hitherto the work of the colonies and of sanatoriums has been handicapped by the fact that, owing to lack of means, patients with dependants cannot afford to remain away from home for long periods. At Edinburgh the colonists during 1910–14 were limited almost entirely to the unmarried. Latterly the depleted labour market has made it possible for even the less fit to obtain profitable employment. It is not easy for the able-bodied consumptive to acquiesce in working at a colony for no wage, while a good income awaits him outside. The Leicester Colony was forced to close in 1916 on this account. The future may well see the payment of a wage to patients in a colony, a principle which has been adopted at some colonies in Germany.

Unless arrangements can be made for the care of dependants it is difficult to see how, in the cases of civilians, prolonged treatment and training can be made possible except on a small scale. Some form of subsidy will be needed to render the principle capable of general application. The discharged service man in enjoyment of a pension is much better situated. The fact that he can leave home in the knowledge that his dependants are provided for gives him advantages which the civilian has never enjoyed. There exists, therefore, an exceptional opportunity for testing the feasibility of subsidised training and treatment, an opportunity which it is to be hoped will be fully exploited, since the results cannot fail to be of far-reaching importance.

UNIVERSITY OF LONDON.—Of the 57 successful candidates at the recent Second Examination for Medical Degrees, Part II., 35 were women and 22 men. Of the former 29 were students at the London (R.F.H.) School of Medicine for Women (two of these also studied at other schools), 4 at King's College, London, 2 at University College, Cardiff, and 1 each at Cambridge and Manchester Universities.

THE RAPID CURE OF HYSTERICAL SYMPTOMS IN SOLDIERS.

BY A. F. HURST, M.A., M.D. OXON., F.R.C.P.,
TEMPORARY MAJOR, R.A.M.C.; PHYSICIAN AND NEUROLOGIST, GUY'S HOSPITAL; OFFICER IN CHARGE OF SEALE HAYNE MILITARY HOSPITAL, NEWTON ABBOT.
AND
J. L. M. SYMNS, M.A., M.D. CANTAB.,
CAPTAIN, R.A.M.C. (T.); NEUROLOGIST, SEALE HAYNE MILITARY HOSPITAL.

INCREASED experience in the treatment of the hysterical symptoms which form one of the largest classes of war neuroses has led to gradual simplification of methods and increasing certainty and rapidity of cure.

Earlier Experiences.

From the earliest days of the war we realised that recent cases could generally be cured quickly and completely by a variety of methods, including simple persuasion and re-education, suggestion with the aid of electricity in the waking state, and suggestion under hypnosis or light anæsthesia. But occasionally improvement was slow and incomplete, and when patients reached us after being under treatment for long periods in other hospitals we did not expect such good results.

Even in hysterical aphonia and mutism, which almost invariably disappeared after a few minutes' treatment, sometimes after lasting for a year or more, the more serious speech defect was often followed by a stammer, which might require careful re-education for several weeks before complete recovery occurred. Indeed, we regarded stammering as one of the conditions in which a rapid cure was rarely possible even in early cases.

Another condition of this sort was tremor: we were confirmed in this conclusion by the opinions which had been expressed by two such distinguished neurologists as Babinski in Paris and Oppenheim in Berlin, both of whom regarded the tremor of soldiers as a special neurosis of emotional origin, which differed from hysterical symptoms in being much less amenable to psychotherapy. We were fortunately less influenced by the writings of Babinski and Froment on reflex neuroses, acceptance of which would lead to the belief that contractures associated with vasomotor and secretory changes are not hysterical and could at the best improve very slowly with physicotherapy.

During the last few months we have come to realise that stammering and tremor, except the fine tremor of the hands and head in pure neurasthenia and hyperthyroidism, and all the cases we have seen which corresponded with Babinski and Froment's description of reflex contractures, are as amenable to treatment as hysterical mutism, aphonia and paralysis, and that they are undoubtedly of pure hysterical origin.

Rapid Cure.

Our more recent experience has shown that the prolonged re-education which we had thought was required to convert into a cure the great improvement which followed the active treatment of long-standing cases directly after admission is unnecessary, and we are now disappointed if complete recovery does not occur within 24 hours of commencing treatment, even in cases which have been in other hospitals for over a year.

If a man with severe hysterical paraplegia of many months' duration is taught to walk in half an hour, and treatment is then discontinued on account of his fatigue, although his gait is stiff and unsteady, he will probably not walk normally until he has undergone re-education for several weeks. But if the officer in charge not only ignores the patient's fatigue, but also his own, and continues the treatment for another half-hour or hour, or even for two or three hours, the patient will end by walking with a normal gait, although, of course, some time will elapse before he completely regains his strength. In the same way a mute or aphonic soldier, who stammers on recovering his voice, should not be left until the stammer is also cured, or he will only recover completely after receiving daily lessons for some weeks.

It is thus not merely in casualty clearing stations that immediate recoveries should occur in the vast majority of cases, but they should occur with equal frequency in hospitals in England. Unfortunately, the hysterical nature of many cases is not always recognised, and patients are

kept in bed for months together for the supposed organic results of shell shock or spinal concussion, or are regarded as suffering from some incurable disease of the spinal cord. Thus we have had seven cases of hysterical paraplegia sent in as disseminated sclerosis and two as primary lateral sclerosis in the last 12 months. Rapid recovery followed the recognition of the true nature of their condition.

Many errors in diagnosis are quite excusable, as organic conditions are often very closely simulated, and without the large experience gained in special hospitals during the war we should have had much difficulty in reaching a correct diagnosis. It is for this reason that all cases of nervous disorders in soldiers, apart from those due to actual injury of the central nervous system or peripheral nerves, should be admitted direct or transferred as quickly as possible into special hospitals, the number of which should be largely increased. Hysterical symptoms would then be diagnosed at an early stage and appropriate measure would be taken to cure the patients at once. Men would be fit to return to duty or to earn their living in civil life in a few weeks instead of having to be invalided from the service more or less completely incapacitated after being in hospital for months or even years.

Prognosis.

The following cases, all of which were treated in the neurological section of the Royal Victoria Hospital, Netley, between December, 1917, and February, 1918, illustrate how rapidly a cure may follow when the hysterical nature of the symptoms has been recognised, in spite of having persisted for many months or even for more than a year.

The question may be asked whether such cures are permanent. Experience shows that relapse is rare if a cure is obtained within three or four weeks of the onset. It is more common the longer the symptoms have lasted, but the liability to relapse is greatly reduced if the patient is given open-air work and kept under observation at the hospital where he was cured for a few weeks before returning to duty. It is for this reason as well as for the sake of the numerous neurasthenic and psychasthenic patients that country hospitals with sufficient grounds to give opportunities for a variety of open-air employment whilst still under military discipline are so desirable.

In very long-standing cases it is generally wise to invalid the patient from the service even if recovery is complete, as a return to the front would be likely to cause a relapse, particularly if the patient is also neurasthenic or otherwise unfit, but a pension of more than 20 or 30 per cent. should never be necessary. So far as we know relapses have not occurred after discharge, except during air raids among men living in London. This is an additional argument, if any are still necessary, for the removal of all patients, officers as well as men, suffering from war neuroses out of London.

Essential Points in Treatment.

We have almost entirely given up hypnotism in the treatment of hysterical conditions, as our results were uncertain, and we have seen so many patients with whom prolonged treatment by hypnosis before admission had proved unavailing and had even given rise to new symptoms. Suggestion with the aid of electricity we rarely employ, except in some cases of flaccid paralysis, in which contractions produced in the paralysed muscles powerfully appeal to the patient's mind, and in resistant cases of speech defects.

Our method now is simple persuasion and re-education continued with manipulation. But an all-important preliminary is the creation of a proper atmosphere. After admission the sister encourages the patient to believe that he will be cured as soon as the doctor has time to see him. If paraplegic or mute, two or three patients in the ward who have been rapidly cured of paraplegia or mutism tell him of their cure. The medical officer sees him some hours later, and after examining him and coming to the conclusion that the condition is hysterical he tells him as a matter of course that he will be cured the next day. By the following morning the patient is fully convinced that the hoped-for cure will take place. As the medical officer is equally convinced that he will cure the patient, the two essentials for recovery are present. The nature of the actual treatment is really immaterial, but simple persuasion has the great advantage of making the patient take an active part in his own cure, and it removes any suspicion of charlatanism from the proceedings.

Illustrative Cases.

1. *Hysterical paraplegia of 8 months' duration following shell shock cured in half an hour 14 days after being awarded a 100 per cent. pension for total incapacity.*—Driver T., aged 22, was blown up by a shell in April, 1917. He felt dizzy, but carried on. In August the regiment was sent to England, and in September, 1917, he collapsed in the barrack square. He was transferred to Netley from another hospital on Feb. 2nd, fourteen days after he had been invalided from the service and awarded a 100 per cent. pension for four months on account of total incapacity. He was suffering from a typical "watch spring tremor" of his legs, and was unable to walk for more than a step without assistance. Putting on shoes or socks was an impossibility. He was treated a few hours arter admission. Relaxation of his muscles was obtained in half an hour by passive movements accompanied by verbal suggestion. He returned to his ward unaided, and next day was able to take part in outdoor employment.

2. *Hysterical paraplegia, talipes, tremor, and stammer of 14 months' duration cured in 1 day.*—Sergeant-Major P., aged 32; blown up in December, 1916; unconscious for some days. He was paraplegic, stammered badly, and had generalised tremor on admission to hospital in England, where he remained 3 months. Then transferred to hospital in London; remained until Dec. 20th, 1917. Treated with massage and electricity; no improvement occurred until air raid in September. This upset him for several days; then found he could walk a few steps, but shook violently whole time. A piece of bone was removed from left foot in October to correct talipes equino-varus which had developed. Operation seems to have had no good effect.

At Christmas he was sent to convalescent hospital; admitted to Netley on Feb. 14th, 1918. He stammered badly and had severe tremor involving both legs, which increased with every voluntary movement, unable to stand; could walk a few unsteady steps with sticks, when further progress was prevented by violent tremor of legs.

As no signs of organic disease were found he was told that treatment on following day would cure him. The presence in ward of three men recently cured of paraplegia helped to convince him. Next morning first one leg and then the other was passively flexed and extended until all rigidity and tremor had disappeared. He was then told to take part in movements by voluntary action, and finally to continue them without assistance. In five minutes he could move both legs whilst lying in bed without any tremor. Up to this time on attempting to speak his expiration became extremely unsteady; he was now told to breathe slowly and deeply, and with each expiration he repeated a single word until he could do this without any stutter. The next stage was to repeat two and then three and four words with each expiration.

Having now had a rest for his legs for ten minutes, the passive and active movements were repeated sitting up. After this he was persuaded to stand and finally to walk without shaking, at first with very slight support to outstretched hands to give confidence. In a couple of minutes he was able to walk without any help, and five minutes later was walking almost normally. As he was feeling faint he was now allowed to rest.

He repeated the talking and walking exercises by himself at intervals during the next few hours. By 5 P.M. he was talking slowly but without any hesitation, and he walked a quarter of a mile with a gait normal except for a slight limp due to talipes equino-varus.

As it seemed impossible to overcome deformity of left foot by manipulation it was thought at first to be be due to some organic injury, especially as an operation had been performed upon it. Moreover, it was colder than right foot and was always wet with sweat, whilst right foot was dry—evidence accepted by Babinski as excluding hysteria and suggesting a "reflex" origin. More vigorous manipulation two days later, continued for 1½ hours, resulted, however, in complete disappearance of the deformity; patient now able to walk without any limp. It is obvious, therefore, that the talipes was hysterical in origin, and any improvement following operation in London must have been due to suggestion.

3. *Hysterical gait and swaying movements and nose-wiping tic of six months' duration following shell shock cured in two hours.*—Pte. B., aged 32, went to France in April, 1917; buried by high-explosive shell in August. In hospitals in France until Dec. 21st, 1917; then sent home; transferred to Netley on Jan. 21st, 1918. No evidence of organic disease, but he could only walk with difficulty; gait extremely unsteady; he threw right leg outwards, somewhat suggestive of organic hemiplegia. On standing his body incessantly swayed backwards and forwards; unless he received support would fall after a couple of minutes. He moved right hand up to nose as if to wipe it all day without intermission, both when resting and trying to walk.

We told him he would receive treatment which would certainly cure him two days later, but we did not intend to do so at once, as we wished to obtain a kinematograph record of gait and tic. This was done at 10 A.M. on Jan. 23rd. He was then treated by active persuasion and re-education without any help by electricity or any other methods of suggestion; improvement was so rapid that by 12 o'clock another kinematograph record was taken; abnormal gait, swaying movements, and tic had disappeared. He not only was able to walk quite well, but could actually run.

4. *Hysterical paraplegia of three months' duration following shell shock cured in 20 minutes.*—[Details of some cases are omitted owing to lack of space.]

5. *Hysterical paraplegia following trench fever and complicated by malingering; mistaken for primary lateral sclerosis; cured by persuasion after persisting for three months.*—Pte. H., aged 38, some weakness in legs ever since he got wet in trenches in February, 1917. In beginning of November, 1917, he developed trench fever with pains in legs. Pain severe; it was noted in France on Nov. 10th that he was disinclined to move his legs. Admitted to English hospital on 19th; both legs rigid and completely paralysed. Diagnosis of primary lateral sclerosis. Knee-jerks exaggerated and followed by excessive spasms of extensor muscles of thigh; ankle clonus said to be well marked.

On admission to Netley on Feb. 1st still unable to make any movements of legs or to sit up. No evidence of organic disease; no ankle clonus; knee-jerks normal when muscles were completely relaxed. Patient was told that he would be rapidly cured, but it was obvious he

did not believe this. The next day an effort was made to cure him in the usual way by persuasion. For five minutes improvement was unexpectedly rapid, the spasms being quickly overcome and passive movements followed by normal active movements. He then suddenly appeared to realise that he was getting well, but did not wish to do so; his legs became extremely rigid again, and every effort to move them met with violent struggles. Repeated efforts were made to overcome his resistance during rest of day; he fought and screamed; no improvement resulted.

As it seemed clear there was now a large element of malingering he was isolated behind screens; nobody allowed to speak to him; not allowed to smoke, read, or write. Diet of only water, bread, and meat. At end of 48 hours he said he would try to walk. With no preliminary passive or active exercises whilst lying down, he sat up without assistance and walked for a few steps with body bent far forward. He then refused to move any more; again isolated.

On Feb. 5th Pte. P., who had come in previous day with hysterical paraplegia and was already completely cured, was shown to him, and he was told there was no reason why he could not walk equally well. He at once got out of bed and walked almost normally. The isolation and food and other restrictions were removed, and after a few days of further re-education recovery was complete.

6. *Hysterical tremor and stammer following shell shock cured in one day seven months later, 25 days after being awarded 100 per cent. pension for "total incapacity."*—Gunner McG., aged 22, was admitted with board papers fully made up, from which the following points are extracted: "(1) It is very difficult to get any definite history out of this patient; (2) A. F. W. 3494 signed with X as he was unable to write owing to the tremor; (3) the special medical board recommended 100 per cent. pension for four months for total disablement."

When admitted 25 days after the board he was suffering from marked tremor of arms and head. Eating was extremely difficult as he could not approximate his hand to his mouth. He spoke with a severe stammer. He was treated within three hours of admission; passive movements of arms and head accompanied by verbal suggestion carried out for 15 minutes caused relaxation of muscles and cessation of tremors and stammer. He returned to ward; next day was on out-door employment and has remained well. The history subsequently obtained is that he was blown up when on duty at an ammunition dump in July, 1917. He was dazed, but returned to duty for one day and then collapsed. His symptoms were increased by an aeroplane raid on his hospital in France. Since then he has passed through seven hospitals.

7. *Hysterical paraplegia and tremor of jaw and limbs following shell shock cured in one day after lasting 16 months.*

8. *Tremor of jaw of three months' duration cured by six hours' continuous treatment.*—Pte. B., aged 36, admitted with tremor of jaw, present for three months, and dating from attack of fever associated with a rigor. Tremor was intensified as he had an extremely bad set of false teeth; rattle heard 50 yards away. The man was a typical "martial misfit." Treated by passive movements of jaw accompanied by verbal suggestion with aid of faradic brush. After six hours' continuous treatment the tremor ceased. He was detained for two months; no sign of recurrence. Then boarded as unfit for service, but able to earn his living in civil life.

9. *Tremor of hands greatly improved in one day after lasting 13 years*

10. *Hysterical nodding movements and coarse tremors of the head and arms following exposure to shell fire cured in an hour after lasting five months.*

11. *Hysterical paraplegia and generalised tremors for three months cured by manipulation and suggestion in half an hour.*—Pte. R., aged 32, was admitted to hospital in France on August 15th, 1917, with trench fever. Hospital bombed while he was sleeping; this seems to have resulted in hysterical paraplegia and generalised tremors. He was sent to us from neighbouring hospital on Nov. 29th, 1917. He could only walk a few steps with sticks; shuffling ataxic gait. A kinematograph record was taken, and he was promised an immediate cure. Passive movements were given; in half an hour complete muscular relaxation and cessation of tremor. A kinematograph record again taken; patient then pushed his bath-chair back to ward, half a mile away. Discharged to Command Depôt on Dec. 10th, 1917.

12. *Hysterical monoplegia and tremor following a mercurial injection cured in a few minutes after lasting for three months.*

13. *Hysterical "main d'accoucheur" and anæsthesia following concussion of median nerve by gunshot wound of forearm cured by manipulation and persuasion in ten minutes after persisting for eight months.*—Sergt. M., wounded in right forearm on April 10th, 1917; compound fracture of middle third of radius. When splints were removed three weeks later typical "main d'accoucheur" deformity, the fingers being rapidly extended and pressed together. Total anæsthesia in area of median nerve. No improvement by November; operation; tendons and median nerve freed from adhesions; contracture aggravated; patient transferred to Netley on Dec. 21st, 1917.

The condition was at once recognised as hysterical, although the well-marked vasomotor disturbance and excessive sweating might have suggested a "reflex" origin, as the deformity was identical with photograph of so-called reflex contracture in Babinski and Froment's book. On day of admission hand was continuously manipulated, patient being persuaded at the same time that it would rapidly relax. In ten minutes complete relaxation; deformity had disappeared. The fingers not moved voluntarily for eight months, could now move normally, but still complete anæsthesia.

The anæsthesia was, doubtless, at first organic in origin, but as it extended considerably beyond area supplied by median nerve we thought it must be hysterical, at any rate in part. Suggestion with the aid of faradism for a few minutes on two occasions resulted in its complete disappearance.

With return of movements the vasomotor and secretory disturbance disappeared. A slight degree of wasting of small muscles of hand was now present; otherwise hand normal in every way. Patient was kept under observation for three weeks; now no incapacity; returned to duty.

February, 1918.

THE ROUTINE USE OF SPINAL ANALGESIA IN GYNÆCOLOGY:

A STUDY OF 1552 CONSECUTIVE CASES.

BY NAGUIB MAHFOUZ BEY,

ACTING PROFESSOR OF GYNÆCOLOGY AND OBSTETRICS, SCHOOL OF MEDICINE, CAIRO; AND ASSISTANT GYNÆCOLOGIST, KASR-EL-AINY HOSPITAL.

BEFORE joining the R.A.M.C. in France Dr. Roy Dobbin, professor of gynæcology and obstetrics in the Egyptian Government School of Medicine, requested me to write an account of the cases operated on under stovaine in the gynæcological department of Kasr-el-Ainy Hospital. This series—1552—includes all the cases in which stovaine was used up to Dec. 31st, 1917. The stovaine injection was given either by Professor Dobbin or by myself, and the notes were written by one of us.

Technique.—Our technique does not differ from that of most other surgeons. We use an all glass syringe, holding 3 c.cm. and graduated in centimetres. The needles, made of steel, are of medium length and rather fine calibre. Thick needles are prone to get blocked by particles of skin or tissue. The puncture is made at different spots according to the operation. For abdominal operations we choose the third lumbar space and in rare cases the second. For dilatation of the cervix the third is also chosen, whereas for vaginal and perineal operations the fourth space is sufficient. The patients receive the injection sitting up with backs arched, and are then placed in the dorsal position with shoulders raised on pillow. A screen placed at level of ensiform cartilage prevents patient from watching operation.

Nature of Operations.

In all 1891 operations were performed. This exceeds the number of patients by 339; many patients have undergone more than one operation. 473 were abdominal operations.

Detailed List of Operations.

Obstetric Cases.

Cæsarean sections	14	Induction of premature labour and incomplete abortions ...	14
Ectopic gestation	9		

Ovaries and Tubes.

Ovariotomy	95	Enucleation of septic tubes ...	15
Partial ovarian resection ...	38	Salpingostomy	21

Uterus, Cervix, and Ligaments.

Wertheim's hysterectomy for cancer of cervix	7	Alexander-Adams's shortening of round ligaments	47
Subtotal hysteromyomectomy	85	Fibroid polypus of cervix ...	27
Abdominal myomectomy ...	19	Amputation of cervix	48
Kelly's ventro-suspension ...	129	Plastic operation on cervix ...	50
Baldy's operation	10	Dilatation and curettage ...	717
Liberation of adherent uterus	11		

Vagina, Vulva, Bladder, and Perineum.

Anterior colporrhaphy and posterior colpoperinæorrhaphy	303	Vesico-vaginal and cervical fistulæ	74
		Recto-vaginal fistulæ	22
Tumours, cysts, and bilharziosis of vagina	25	Complete tear of perineum ...	13
Hæmatocolpos and vaginal atresia	25	Tumours and elephantiasis of vulva	20

Miscellaneous.

Retro-peritoneal sarcoma ...	2	Stone in bladder	2
Peritonitis and perimetric abscesses	18	Ventral and inguinal hernia	5
		Piles	8
Appendicectomy	6	Exploratory laparotomy ...	12

We have successfully submitted to stovaine analgesia cases which would have run a very serious risk under general anæsthesia. Some of the myomata and ovarian cysts in this series reached the weight of 38 lb. In one ectopic gestation the pregnancy reached almost to full term without rupture of pregnant tube.

The duration of anæsthesia was sufficient for cases that required less than 90 minutes. Only cases of cancer done by Wertheim's method required so long, and in them a little chloroform was necessary to finish the operation.

Results.

The analgesia was considered complete when there was complete relaxation of the abdominal muscles, pain was entirely absent and patient admitted that she did not feel any pain whatever. The results can be summarised as follows:—

In 3 cases it was not possible to reach the canal.

In 20 cases the injection was given, but no analgesia followed. Ten of these occurred in the first 100 cases. It is noteworthy

that other ampoules from the same box were used on the surgical side without success. The failures occurred in groups of 3 and 4, and we believe that most, if not all of them, were due to defective solutions.

Partial failure occurred in 15 cases. A few drops of chloroform was all that was necessary to finish the operation.

We have therefore had about 1·28 per cent. complete failures and 0·90 per cent. partial failures. There were no deaths from stovaine.

Course and extent of the analgesia.—The course of the analgesia varied with amount injected and place of injection. Immediately after the injection perineal sensation was abolished. In about 3–5 minutes (in rare cases 8–10) the analgesia would have gradually extended up to the umbilical region if injection was made in fourth lumbar space and to the ensiform cartilage if in the third. In a few cases sensibility to heat was retained for some time after complete analgesia had been established.

Accompanying symptoms.—In a small proportion of cases (less than 2 per cent.) nausea occurred. Actual vomiting occurred in about 3 per cent., but never lasted more than a minute. Relaxation of sphincter during analgesia with incontinence of fæces occurred in a few cases. Signs of depression, such as yawning, pallor of face, and perspiration, rarely occurred and have seldom caused anxiety. Pulse at end of operation was in many cases stronger than at beginning.

Post-operative symptoms.—In about 1 per cent. of the cases a certain amount of headache, easily amenable to treatment, was complained of. The temperature rose a degree or even two on second and third days in some of our early cases. Vomiting after operation was conspicuous by its entire absence. Paralytic sequences, whether transitory or permanent, have never occurred.

The Solution Used.

Stovaine billon was used in about half the cases. Each ampoule contained a little over 2 c.cm. of the following: Borate of epirenin, 0·00013; stovaine, 0·04; sod. chlor., 0·0022; distilled water to 1·00.

The amount injected is the same for a big or small operation—viz., 2 c.cm. of the solution containing 0·08. In some cases we injected half or three-quarters of the dose, but the effect was not quite so good and passed off more quickly. As an exception we may mention colporrhaphies, in which half a dose is sufficient, but even there it is better to inject a full dose, as it may be found necessary to do something more.

We are now using with even better results a solution prepared in the school chemical laboratories under the supervision of Dr. Bahry Bey. The formula used is: Sod. chlor., 0·0011; stovaine, 0·04; water, 1 c.cm. It is prepared as follows:—

The sodium chloride is dissolved in the water. The solution is sterilised in the autoclave for 15 minutes and then left to cool down. The stovaine is dissolved in solution and filtered through a good filter previously sterilised. It is then heated on a water-bath for ten minutes at 80°–90° C. After cooling it is stored in sterilised ampoules. The whole process is carried on aseptically. Attempts to sterilise the stovaine solution by boiling have resulted in the decomposition of the stovaine and is not necessary, stovaine itself being antiseptic.

Conclusions.

Stovaine analgesia was greatly welcomed by our patients. Most Egyptian women have a great dislike to general anæsthesia. Many instances have occurred of patients refusing to have an operation done under chloroform, but agreeing to undergo the operation under stovaine analgesia.

The preparations are made and the stovaine injected before the students come into the theatre. The patient is covered up with sterilised towels, and is less exposed than during an examination in the out-patient department.

After having watched this number of patients during their operations and convalescence, and having followed many of them for years afterwards, we have no hesitation in asserting that stovaine is, in our opinion, far superior to chloroform in all gynæcological operations. During the operation the complete relaxation of abdominal muscles and the evenness of the analgesia are a great help to the operator. The absence of vomiting during the convalescence prevents any strain on the stitches. The freedom from shock and all respiratory troubles are points in favour of stovaine.

TWO NEW FRENCH METHODS FOR STAINING BLOOD FILMS AND BLOOD PARASITES.

BY L. TRIBONDEAU.
MEDICAL OFFICER OF THE FRENCH NAVY.

THESE two methods,[1] now brought before the readers of THE LANCET, are very practical, not only because the technique of the colouration is simple, but especially because the staining solutions can be prepared without difficulty by anybody. They are related to the well-known methods of Leishman and provide efficient substitutes for the secret processes of Giemsa and other German writers.

I. *Colouration Method with Stain III.*

Of the two methods, this one (neutral solution of eosinate of methylene-blue converted by ammonia) is more rapid in execution and gives more complete results, but it requires very pure and neutral distilled water. Certain commercial distilled waters do not possess these qualities.[2]

Preparation of Stain III.—Heat some distilled water to boiling point. Divide.

(A)—50 c.cm. in enamelled basin; add 0·20 g. pure medicinal methylene blue; shake to dissolve.

(B)—75 c.cm. in a glass; add 0·30 g. water-soluble eosin (French eosin); shake to dissolve.

Pour B into A by successive fractions. After each addition of B mix for some time with glass rod; then place on glass slide drop of mixture from end of rod. This drop is at first deep blue and free from precipitate. Then, as proportion of eosin is increased, the blue becomes more pale and a precipitate appears. Finally precipitate increases and colour of liquid turns from blue to rose. Stop addition of eosin as soon as this change occurs. It generally requires a little more than 50 c.cm. of B to obtain this result, which is quite easy to observe.

Add 4 c.cm. of ammonia to mixture thus obtained. Mix. Heat to 120° C. in autoclave for 20 minutes in enamelled basin covered with inverted glass funnel. Remove from autoclave; stir with rod and allow to cool completely.

Filter through small white filter-paper well folded all contents of basin. Discard filtrate. Keep only precipitate, which is almost entirely retained on filter, and of which a small portion remains deposited on side of basin. Dry precipitate by placing in incubator at 37° C. the filter widely open on several layers of absorbent paper, and also basin.

When drying is complete (no trace of water must remain in order that ammonia may be completely volatilised) place filter in basin and dissolve as much as possible of dried stain by pouring into basin, in successive fractions, 100 c.cm. of glycerinated alcohol (absolute ethyl alcohol, 90 c.cm.; neutral glycerine 10 c.cm.) and crushing powder with large glass rod. Transfer the 100 c.cm. of solution into flask, taking care to transfer also all undissolved stain. Shake flask from time to time. Filter after 12 to 24 hours.

Technique of staining.—First fix preparation with undiluted Stain III. For this, slide carrying blood (previously spread in thin film, dried simply by moving in air, and marked off by a glass pencil line) is placed on table, film upwards. Cover film with 0·2 c.cm. of Stain III. (approximately 12 drops). Cover with half of Petri dish to prevent too great evaporation, especially in summer. Allow to act three minutes.

Then stain by adding to Stain III., on slide itself, 0·6 c.cm. of distilled water (approximately 12 drops). Mix water and stain by few movements of slide. Replace on table. Allow to act for average time of 12 minutes without moving. Wash rapidly with jet of distilled water. Dry immediately (by passing wet preparation for two seconds over flame and blowing vigorously on it).

II. *Colouration Method with Stains I. and II.*

When good distilled water is not available this second method (*neutral solution of eosinate of natural methylene blue and alkaline solution of eosinate of methylene blue converted by ammonia*) is preferable to first; it is less delicate.

Preparation of Stain I.—Pour into heat-resisting flask—

Neutral glycerine	5 c.cm.
Absolute ethyl alcohol	45 c.cm.
Pure medicinal methylene blue	0·20 g.
Water soluble eosin (French)	0·05 g.

Dissolve rapidly by plunging flask in very hot-water bath and shaking. Allow to cool. Pour into glass-graduated

[1] C. R. Soc. de Biologie de Paris, May–June, 1918.

[2] One can correct a defective water by redistilling, after addition of a little silver carbonate obtained by precipitation of a silver nitrate solution with carbonate of soda, but this is complicated.

measure; make up to 50 c.cm. with absolute ethyl alcohol. Filter and cork in a flask.

Preparation of Stain II.—Pour into heat-resisting flask—

Neutral glycerine	25 c.cm.
Ethyl alcohol at 95 per cent.	15 c.cm.
Pure medicinal methylene blue	0·20 g.
Water-soluble eosin (French)	0·05 g.

Dissolve in water bath as with I. Allow to cool. Pour into glass-graduated measure, and make up to 40 c.cm. with 95 per cent. ethyl alcohol. Return into flask.

Add 4 c.cm. of ammonia. Mix. Heat to 120° C. in autoclave for 20 minutes in open flask. Remove from autoclave and allow to cool somewhat. Pour into glass-graduated measure and make up to 50 c.cm. with 95 per cent. ethyl alcohol. Return into flask, which is corked only after a day or two.

Technique of staining.—First fix preparation with undiluted Stain I. For this, place slide on table, film upwards. Cover film with Stain I. Cover with Petri dish. Allow to act three minutes. Wash with jet of distilled water. Get rid of surplus water by shaking; wipe under side of slide; place it on edge of glass or crystallising dish without drying film.

Stain by pouring on preparation Stain II. diluted and hot. For this have small test-tube of 1 cm. diameter marked at 2 c.cm.; pour distilled water to mark; heat tube held aslant in flame until appearance of first bubbles of air; add to the 2 c.cm. of hot water 4 to 5 drops of Stain II.; pour hot over film. Allow to act 15 minutes.

Wash with jet of distilled water. Dry immediately (heating and blowing). Remove excess of blue by pouring on dry preparation held aslant watery solution of tannin (1 in 20) until film becomes rose-coloured. (It is necessary to avoid differentiating moist films because preparations would become spotted with blue. The solution of tannin is prepared by dissolving 1 g. of tannin "à l'alcool" in 20 c.cm. of very hot water. One adds a little camphor to prevent growth of moulds.) Wash at once with distilled water. Dry immediately.

N.B.—One can omit I., fixing simply with alcohol, but it is then necessary to stain with II. for 30 minutes.

THE ISOLATION OF DYSENTERY BACILLI FROM THE FÆCES.

BY HENRY WHITEHEAD, M.D., D.P.H. MANCH., M.B., B.S. LOND.,
TEMPORARY CAPTAIN, R.A.M.C.; BACTERIOLOGIST TO —— GENERAL HOSPITAL;
AND
J. KIRKPATRICK,
LANCE-CORPORAL, R.A.M.C. (T.F.).

OUR object is to describe what we consider the best method of isolating *B. dysenteriæ* from the fæces.

Collection and Selection of Fæces for Examination.

(*a*) *Duration of disease.*—Specimen must be obtained during and as early as possible in acute stage of illness. After a week isolation of *B. dysenteriæ* becomes increasingly difficult, and at end of fortnight the organisms have disappeared in a large majority of cases unless the cases have relapsed.

(*b*) *Appearance of specimen.*—1. *Naked eye:* The typical stool is almost completely composed of pus and mucus, in most cases streaked with blood; usually pinkish in colour, giving the impression of greyish-white opaque flakes of pus in mucus tinged with blood. In these cases the collection is simple. When the stool is of a mixed character the pus and mucus portion must be selected for investigation. The sample should be free from urine. The bed-pans must not be washed out with disinfectant before being used for obtaining specimen. In some cases of Flexner-Y infection the stool is fluid, containing flakes of mucus and pus. As duration of disease increases character of stool changes. Instead of blood-stained pus and mucus one finds *bile*-stained pus and mucus, especially in Shiga infections.

2. *Microscopic:* Every specimen must be examined microscopically for protozoa. Microscopical examination is most important as a guide to selection of stools for culture. The appearance in an acute case is almost diagnostic in itself. The field is covered by numbers of cells of various kinds—pus cells chiefly, red blood corpuscles, and epithelial cells, especially macrophages. Pus cells and macrophages are the important guides. If the sample is non-cellular, although mucus be present, it is of little use culturing it except in case of possible carrier. We have cultured many hundreds of stools of this nature with negative results.

(*c*) *Age of specimen.*—*The stool must be cultured in a fresh state*, as the bacilli of dysentery quickly die off in a stool. If the sample cannot be obtained at a convenient time it should be placed in an ice-chest. A fresh specimen from a case on second day of disease was examined and *B. dysenteriæ* Shiga was isolated in almost pure culture. Another specimen from the same case was examined as follows:—

Fresh specimen (fifth day of disease) plated immediately, 27 colonies of *B. Shiga*.

The specimens plated after standing at room temperature or in ice-chest gave the number of colonies of *B. Shiga* stated:—

After standing at room temp.:		After being in ice-chest:	
For 1 hour	21 colonies.	For 1 hour	27 colonies.
,, 2 hours	17 ,,	,, 2 hours	23 ,,
,, 3 ,, ...	12 ,,	,, 3 ,, ...	24 ,,
,, 12 ,, ...	3 ,,	,, 12 ,, ...	11 ,,
,, 24 ,, ...	1 colony.	,, 24 ,, ...	3 ,,
,, 36 ,, ...	No ,,	,, 36 ,, ...	2 ,,

A fresh specimen from an acute case was cultured, and *B. dysenteriæ* Flexner was isolated easily, the majority of colonies on the plate being of this organism.

The day after a six hours' old sample from the same case, with similar naked-eye and microscopical appearances, was cultured. Not one colony of *B. dysenteriæ* was present on the plate.

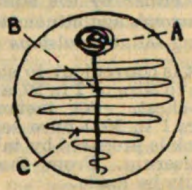
These are most striking facts which prove the absolute necessity of culturing *fresh specimens*. We have recorded many similar examples.

It is recommended that the MacConkey's medium used be made up with *double the strength of neutral red*—i.e., 0·5 c.cm. of a 1 per cent. solution to every 100 c.cm. of agar.

Method of Plating.

(*a*) With sterilised platinum loop pick from fresh specimen of fæces a small portion consisting of pus and mucus.

(*b*) Wash it well in sterilised normal saline and remove it *immediately* with loop, allowing excess saline to drain away along sides of tube.



A, Pus and mucus. B, Vertical stroke. C, Horizontal strokes.

(*c*) Rub and spread washed pus and mucus well on to surface of MacConkey plate at position (A) shown in diagram.

(*d*) Sterilise loop and make vertical stroke (B) from first inoculation.

(*e*) Again sterilise and make a series of horizontal strokes (C) across vertical one without removing loop.

(*f*) Incubate 18–24 hours at 37° C.

By this method the portion of specimen most likely to contain *B. dysenteriæ* is selected. The washing helps to remove various coliform organisms, &c., not wanted. The rubbing and spreading of pus and mucus tends to break up pus cells, liberating bacilli sought for. The stroke method with two sterilisations of loop gives three dilutions, a good separation of colonies on plate, and does away with necessity of using two or more plates for same case sometimes recommended.

Selection from Plate of Likely Colonies.

(*a*) Discard lactose fermenters.

(*b*) Of the others, pick off with sterilised straight platinum wire one of each type of colony present. Care must be taken to touch only one colony at a time. It is impossible to distinguish, either by naked eye or by means of a lens, between *B. dysenteriæ* and many other non-lactose fermenters, especially typhoid group, some forms of *B. fæcalis alkaligenes*, Morgan No. 1, and paracolon bacilli, with any degree of certainty.

It should be remembered that colonies of *B. dysenteriæ* are not clear, as sometimes stated, but are dull grey in colour and slightly opaque. *B. Shiga* colonies are always more opaque than *B. Flexner* or *Y*.

It is interesting to note here that *B. dysenteriæ* are sometimes retarded in growth and appear on plate after standing at 30° C. for 24 hours. We have isolated on an average an additional 20 per cent. of *B. dysenteriæ* by incubating in usual way for 24 hours and then allowing plate to stand another 24 hours at 30° C.

Identification of Organisms.

This is shown by their effect on sugars, indol, and litmus milk, and by agglutination with specific sera.

(*a*) Subculture colonies selected in Durham's fermentation tubes containing litmus-lactose-peptone-water.

(*b*) Incubate 10–12 hours at 37° C.

(*c*) Again discard lactose fermenters. (*Note.*—It is possible to pick off lactose fermenters from the plates, as some may be quite pale when young, and the presence of *B. fæcalis alkaligenes* sometimes neutralises the acid produced.)

(*d*) Subculture on to trypsin-agar slopes and into litmus-mannite-peptone-water.
(*e*) Incubate for 12 hours.
Then proceed according to the following:—

Lactose.—Acid or acid and gas: Discard. No change: Test as follows.
Mannite: No change.—1. Motile: May be (1) *B. fæc. alkal.*, or (2) *Morgan's No. 1.* Confirm by reaction with other sugars, indol, and litmus milk.
2. Non-motile: Test agglutination with Shiga antiserum. Negative: May be (1) *non-motile B. fæc. alkal.*; (2) *possible inagglutinable B. dysenteriæ* Shiga. Positive: *B. dysenteriæ* Shiga.
Mannite: Acid.—1. Motile: Further investigation if necessary. Not *B. dysenteriæ.*
2. Non-motile: Test agglutination with Flexner and Y antisera. Positive: *B. dysenteriæ* Flexner or *B. dysenteriæ* Y. Negative: Test effect on other sugars, indol, litmus milk for possible atypical *B. dysenteriæ.*
Mannite: Acid and gas.—Further investigations if necessary. Not *B. dysenteriæ.*

Note on Agglutination.

When a rapid diagnosis is required likely colonies may be investigated direct from the plate; this is often possible in early acute cases where a large number of colonies of *B. dysenteriæ* appear.

An emulsion having been made in normal saline of suspected colonies, a small loopful of this is put on slide, a similar loopful of Flexner-Y antiserum (1 in 100) is mixed thoroughly with it; dilution 1 in 200. A cover-slip is placed upon mixture and fluid examined microscopically. Immediate agglutination is diagnostic. A control, with saline instead of antiserum, is necessary, as some organisms, notably *B. fæcalis alkaligenes*, and one type of paracolon bacillus sometimes clump in normal saline. The same may be done using Shiga antiserum. These rapid results must be confirmed later by sugars, &c., and by careful agglutination by a macroscopical method.

The agglutination tests referred to above may be carried out either by the admirable method described by Garrow (Garrow's agglutinometer [1]) or by the ordinary tube method, using saline emulsions from trypsin-agar slopes.

It is convenient to standardise the specific sera for stock use to titre of 1 in 50, and these stocks must be stored in an ice-chest. For instance, if the antiserum supplied is titre 1 in 5000 pure serum and already diluted 1 in 10 the stock is prepared by taking 9 parts of saline to 1 part of the antiserum. From the stocks any dilution required can easily be made.
It is advisable whenever possible to use a separate antiserum for Flexner and for Y, because we have noted that some Flexners do not come down to Flexner-Y serum, but do so with Flexner serum alone. Many Flexner infections may be missed in this way.

Note.—If Widal controls are made with patients' sera it is necessary to take into consideration any previous administration of antidysenteric serum or vaccine, and to draw conclusions accordingly.

Results.

We have isolated only two *B. dysenteriæ* Flexner out of some 5000 examinations of stools which contained neither pus nor mucus; and never a *B. dysenteriæ* Shiga. This shows the futility of examining stools of this character.

Our findings of the classical types of *B. dysenteriæ* in stools containing pus and mucus or mucus alone are as follows:—

200 cases investigated by method described.
101 typical stools containing pus and mucus. Findings: 46 *B. dysenteriæ* Shiga, 30 *B. dysenteriæ* Flexner-Y—i.e., *75 per cent. positive results.*
Remaining 99 had not the typical naked-eye appearance, but contained mucus.
The findings in the 200 cases were: *B. dysenteriæ* Shiga, 68; and *B. dysenteriæ* Flexner-Y, 41—i.e., 54 per cent. positive results.

From results obtained we are bound to conclude that the classical types of *B. dysenteriæ*—Shiga, Flexner, and Y—are the true causes of bacillary dysentery. The 75 per cent. positive findings in selected cases is surely proof in itself. It is probable that the 25 per cent. negative findings may be explained by (1) specimens collected too long before being cultured, (2) duration of disease too long, with disappearance or paucity of dysentery bacilli. Moreover, the results fully demonstrate the value of the methods described.

As regards atypical forms of dysentery bacilli, on which so much work has been done recently, it is more than likely that these are associated organisms and not the true causes of bacillary dysentery. The so-called inagglutinable types of Shiga and of Flexner-Y are often morphologically unlike the classical types, being distinctly smaller and thinner, and the colonies are more "slimy" in character. We have often isolated these types from plates on which the classical types were found, and from many stools apparently normal. In many cases the reaction of the patient's serum has been tried in its effect on these atypical forms with negative results. In no case have we failed to get positive (controlled) reaction when classical types have been isolated, the test being done before any administration of anti-dysenteric serum.

Sept. 30th, 1917.

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF TRENCH FEVER IN A CIVILIAN.

BY J. H. E. BROCK, M.D. LOND., F.R.C.S. ENG., D.P.H.,
LATE HONORARY PHYSICIAN TO THE WESTMINSTER GENERAL DISPENSARY.

AN account of the following case may prove of interest and indicate the possibility of an outbreak of the disease amongst the general population. During the case I had the privilege of meeting two consulting physicians. The first, after probably the end of the second rise of temperature, hesitated to accept my diagnosis of trench fever, but would commit himself to no opinion, merely saying that, whatever the infection, he thought it was at an end, and that the patient would soon be on the road to recovery. The second, Dr. Farquhar Buzzard, unhesitatingly accepted the diagnosis at the end of the probable third rise in temperature, and four days before it rose again and the final stage of the illness began.

I have used the word "probable," as applied to the rises in temperature, because I think, from the subsequent course, that the patient first consulted me during an afebrile interval following the initial rise. His temperature on that day was perfectly normal; and a careful examination revealed nothing to explain the severe pains in his legs. I could arrive at no conclusion; and it was not till I was sent for five days later, when the patient had returned from a week-end in the country, that my suspicions as to the real nature of the illness were aroused.

Patient, aged 62, a business man, consulted me on May 17th, 1918, complaining of a general aching, severe pains in legs, headache, and slight chilliness during previous three days. No vomiting; bowels quite regular. T. 98·4° F. P. 84, irregular. Tongue dry and furred. The physical signs were only those of old mitral stenosis, of which I had been aware for 20 years—viz., apex beat in sixth left space, 1½ inches outside nipple; presystolic thrill, loud presystolic murmur running up to first sound and followed by second sound at apex; base nil. Over base of left lung numerous moist râles; few moist sounds at right base. Liver a good hand's breadth below costal margin; spleen not palpable. Urine normal. I wrote him a salicylate and alkali mixture. Patient was going to stay with his brother for week-end; I offered no objection.

I next saw patient on evening of May 22nd. T. 102·6°, P. 108, irregular, agonising pains in lower limbs from hip to feet, worse on right side; some pain in arms. Pain was most severe in shins; some tenderness on pinching calf and thigh muscles. Cardiac and pulmonary signs as already described. No strabismus; he could flex chin on to sternum; no rigidity of legs, arms, or back; Kernig's sign not present; knee-jerks absent; plantar reflex flexor, sensation normal; no loss of motor power in limbs; sphincters normal. Abdomen was flaccid; liver enlarged as before; spleen beneath left costal margin for about three fingers' breadth, not tender; lymphatic glands not enlarged. Urine was acid, sp. gr. 1034; no albumin, sugar, or casts; trace of bile pigment. The patient was put on gr. 6 acetosalicyl acid, 2 gr. of quinine, and 1 gr. of caffeine cit., every four hours. This gave him a certain amount of relief from pain, and enabled him to have short sleeps.

On May 24th T. fell to normal. On this evening, at first consultation, an entirely favourable opinion was expressed. With remission of temperature partial relief from pains. Phenazone and bromide of sodium were next tried for relief of pain; not much benefit.

At 8 P.M. on May 25th T. rose again to 99·6°; return of pains in legs with severity. From this date till May 30th T. elevated; 101° on evening of 28th. On 30th T. again normal. Throughout this period pains in limbs and sleeplessness were chief symptoms. For former a mixture of salicylate of soda and bicarbonate of soda t.d.s. with 5 gr. of quinine once a day were tried, and next salicylate of soda and iodide

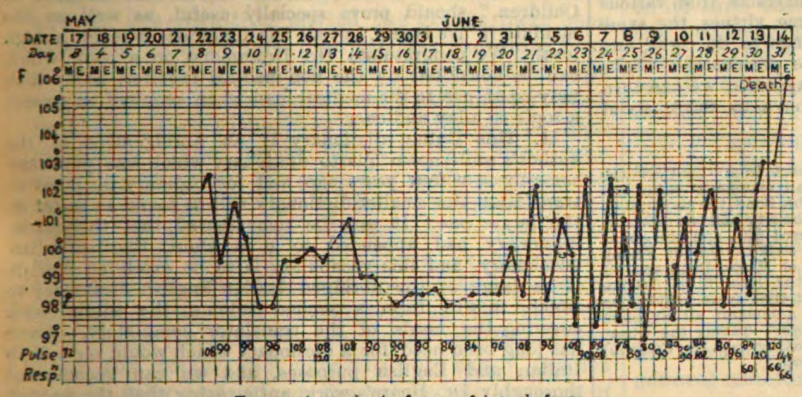
of potassium, but without success. Bromidia and then chloralamide were prescribed, the former with some relief, the latter without any.

On May 31st patient was seen by Dr. Farquhar Buzzard, who confirmed my diagnosis. He advised guaiacol carbonate, 10 gr. t.d.s., for the pains; results no better. On June 1st slight œdema of feet. Put on mixture of am. carb. gr. 3, tinct. digitalis m. 10, and tinct. nux vom. m. 5. t.d.s.; also three cachets of guaiacol carbonate a day. At night a draught of bromide of potassium, chloral hydrate, and tinct. opii.

On June 3rd T., normal for 5 days, rose again; pains again became severe. Digitalis mixture was continued from this time onwards till death; the digitalis being gradually increased until he was taking 18 m. t.d.s. Guaiacol discontinued; put on salol 5 gr., quin. sulph. 2 gr., calomel 1/12 gr., t.d.s., for the pains; certain measure of relief. For sleeplessness he had medinal, at first with great success. This was, towards end, replaced by paraldehyde 3i. The latter took five or six hours to act, and then produced prolonged and deep sleep.

From June 3rd onwards T. followed a characteristically septic course, 101° to 102·6° at night, subnormal in morning. On June 8th he had two rises of temperature to 101° and 102° respectively, normal between; no rigor. Despite the increasing doses of digitalis, œdema of lungs and feet increased, moist sounds being audible over both lower lobes in front and over whole back; œdema of lower extremities extended nearly to knees. On June 13th signs of pneumonia were audible over middle lobe of right lung. T. 103°, gradually creeping up to 106° on the afternoon of June 14th. Patient died same night.

Comments.—It is now established that the virus of trench fever is transmitted by an infected louse, either by scratching and rubbing in the excreta, or apparently sometimes by a simple bite. It has been recognised for some time that being actually in the trenches or fighting zone is not a *sine qua non* for contracting the disease. Given infectious material and lice to carry it, the disease may spread to those in contact. If that can happen in France, there is no reason why the same thing should not occur in this country, to which large numbers of men are constantly returning from the front, many of whom have had the disease.



Temperature chart of case of trench fever.

An outbreak of trench fever being a possibility amongst the civilian population, the point to be settled is the accuracy of the diagnosis. Was this case one of trench fever or not? The organism of trench fever not having been isolated up to the present, bacteriology can afford us no help. The diseases that would require to be ruled out as possible explanatory causes are typhoid or paratyphoid, malaria, acute rheumatism, Weil's disease, and sepsis.

The course of the pyrexia, broken by days of normal temperature, disposes of the typhoid group. The patient had not been out of England for years, had never previously suffered from malaria, showed no periodicity in the elevations of temperature, and had no vomiting, chills, or sweats. From first to last no joint was affected; the pericardium escaped, and no fresh valvular lesion appeared—points that make acute rheumatism a very improbable diagnosis.

The pyrexia, pains in the limbs, enlargement of spleen and liver, made me think of Weil's disease or epidemic jaundice as a possibility. The enlargement of the liver, however, was of old standing, only that of the spleen being recent. The urine contained some bile pigment, but there was an absence of intense jaundice, and no nephritis. A careful examination showed no septic focus anywhere.

Up to June 3rd the pyrexia followed the course usually described in trench fever. I think it highly probable that when the patient first consulted me on May 17th, after he had been ill three days, he was at the end of his first bout of pyrexia, and that the rise that began on June 3rd was therefore the fourth in the series. From this date onwards the temperature was unmistakably septic in its course, due, in all probability, to the damaged mitral valve being attacked by the organism of trench fever. The myocardium was also profoundly affected and showed a progressive failure to cope with the circulation, evidenced by increasing œdema of the lungs and lower extremities. The pneumonia of the middle lobe was in all probability embolic in origin and part of the same septic process.

Hampstead, N.W.

A CASE OF TRANSIENT HEMIPLEGIA.

BY H. H. MILLS, M.D. LOND.

THE case reported below is remarkable in view of the passing of the signs of a complete hemiplegia under actual observation.

At 7 A.M. on May 1st patient, a Jewish lady, aged 28, woke with her left side paralysed. I was telephoned for and very soon was able to note an apparently complete left-sided hemiplegia. Left leg and arm completely flaccid and useless. Face drawn to right; speech much impaired. Tongue protruded straight; pupils reacted normally; no strabismus. In considerable mental distress, the patient was able to say that "she knew what she wanted to say, but could not say it properly." She was mentally clear, and had gone to bed the night before perfectly well. This was confirmed by her sister, who occupied the same room. I secured a nurse. At 11 A.M. the condition was precisely as in early morning, but to my surprise I heard that between 8 and 9.30 the paralysis had passed away. Heart sounds normal; no signs of cardiac degeneration; blood pressure normal; urine gave no indication of disease.

At 9 P.M. Dr. Lauriston Shaw saw the patient; condition precisely as before. As we were watching the patient and had satisfied ourselves that there was no loss of sensation and that the jerks and reflexes were normal, the facial muscles of the left side gradually resumed their normal function and the facial expression became equalised on the two sides. In a similar way the muscles of the arm and leg resumed their function. Beyond a certain feeling of "crampiness" there was nothing to remind us of the clinical picture we had observed five minutes before. It should be stated that at 6 P.M. there was frontal headache on right side and patient had vomited. Tongue clean throughout.

On May 2nd patient was perfectly normal, but the nurse informed me that there had been a return of the paralysis for about a quarter of an hour in the night. The patient was conscious of the onset and the passing of the attack. From this time on until July 7th there has been no return of the paralysis and the only sign of anything possibly abnormal has been a certain amount of fatigue and some mental irritability (similar to such symptoms as are so commonly seen after any illness causing shock). There is not the slightest sign of any lesion affecting the nervous system or the musculature of the left side. Wasserman reaction negative; cerebro-spinal fluid not examined.

The previous history is interesting, as in August, 1917, for about three days, there was a feeling of "creepiness" in left side of face and numbness and feeling of weight in both arm and leg of left side. Also for years past patient has suffered from very cold feet and hands, for which "she has often put her hands in hot water for a time."

The diagnosis presents an interesting problem. The signs were so extensive as well as so transient that a temporary deficiency of blood-supply to the upper nervous centres seems to be the most likely explanation. Local spasm of the cerebral arteries has been regarded as a possible cause of migraine, and spasm of the retinal arteries has been actually observed with the ophthalmoscope during an attack of hemianopia. It would be interesting to know if any of your readers have notes of a similar case.

St. Mary Abbott's Terrace, W.

THE garden party held on July 16th resulted in a benefit to the Royal Medical Benevolent Fund Guild of £1350 after expenses had been paid, an outcome of practical benevolence upon which all concerned must be congratulated.

Reviews and Notices of Books.

Social Life in Britain from the Conquest to the Reformation. Compiled by G. G. COULTON, M.A. Cambridge: At the University Press. 1918. Pp. 540. Price 15*s.* net.

EVERYONE who is interested in the life of the Middle Ages knows Mr. Coulton's former books—namely, "A Mediæval Garner," "From St. Francis to Dante," "Chaucer's England," "Mediæval Studies," and the possibly less known "Friar's Lantern." His latest book, which is now before us, should be studied in connexion with "A Mediæval Garner," which gives a more general view of mediæval life, not being confined to Britain. For one feature which characterised mediæval life, and one which fell into abeyance between the Reformation and the end of the Napoleonic wars, was a great intercourse between these islands and the continent. This was due to several causes, among which may be mentioned the general use of Latin as a spoken language among "clerks" as well as of French, among the upper classes at any rate, until about 1360. Also, except for the great division between the East and the West, there was for all practical purposes religious unity, though there were plenty of divisions amongst the various regular orders, and between them and the seculars, neither were religious-minded lay folk always free from doubts. Mediæval university students, too, wandered from one university to another far more than they did in later years. Human nature, however, has changed but little in the main, and any one who reads Mr. Coulton's extracts from various mediæval chroniclers will find the same virtues, the same faults and weaknesses, the same strivings to do right, and failures, as are evident every day in the present age. Take a concrete instance. Most of us to-day when we can turn our thoughts from the battle front have to think about rationing and profiteering.

As to rationing:

On p. 376 of Mr. Coulton's book is an extract from the Coventry Leet Book noting that in 1520 "the price of all manner of corne and graynes be-ganne to rise," wherefore Master John Bond, the mayor, took a survey as to the number of people within the city and the quantity of the various grains. The population numbered 6601 and the grains at the time of the survey (October) 204 qrs. 5 strike. On the Friday before Christmas Day, owing to the exertions of Master Bond and his friend, there was brought "to help to susteyne the Cyte" 78 qrs. 6 strike of all kinds of grain; moreover, "ther was at that tyme xliij bakers within the Cyte, the wiche dyd bake wekly a-mongest all six score quarter of whet and xij besydes pese and Rye." Taking the wheat only, this gives over 9 lb. per head per week, making (says Mr. Coulton) "at least 6 lb. even of fine white bread per person."

As to profiteering:

In 1416 the wife of Hildy, the poulterer (London), and the wife of John Mede were committed to prison because against the proclamation of the Mayor the wife of Hildy sold four woodcocks for 20*d.* and the wife of Mede refused to take 12*d.* for two partridges. The tariff of 1343, which apparently was still in existence, fixed the price of a woodcock at 3*d.* and a partridge at 5*d.* Roughly speaking, we must reckon pence as shillings to convert them into modern values.

Food regulations are interesting:

In 1378 the Mayor and Aldermen of London issued a tariff fixing the prices of meat and poultry roasted or baked in a pasty; thus a roast rabbit cost 4*d.* and a capon in a pasty 8*d.* But in 1379 we note that the Pastelers of the City of London "have heretofore baked in pasties rabbits, geese, and garbage, not befitting and sometimes stinking, in deceit of people ..... therefore by assent of the four Master Pastelers ..... it is ordered and assented to that in the first place no one of the said trade shall bake rabbits in pasties for sale." Is this order an early example of the common idea that rabbit pie is poisonous?

In the Section on Medicine there is an interesting note showing the danger of unqualified practice—namely:

"In 1354 the Prior of Hogges, Master Paschal, Master Adam de la Poletrie, and Master David de Westmerland, surgeons, were sworn before the Mayor, Aldermen, and Sheriffs to certify as to an enormous and horrible hurt on the right side of the jaw of Thomas de Shene appearing, whether or not such injury was curable at the time when John le Spicer of Cornhulle took the same Thomas under his care to heal the wound aforesaid; Who say upon their oath that if the aforesaid John the Spicer at the time when he took the said Thomas under his care, had been expert in his craft or art, or had called in counsel and assistance to his aid, he might have cured the injury aforesaid; and they further say that through want of skill on the part of the said John the Spicer, the said injury under his care has become apparently incurable."

John the Spicer was, we suspect, an apothecary who tried to practise surgery.

After the regulations to which we have referred above concerning the food of the whole, it is sad to find that in 1356, in an agreement between the Chancellor, Masters and Scholars of Oxford on the one hand, and Richard d'Amory on the other, it was decided that the University should have jurisdiction over the market with power to seize all bad victuals and to punish delinquents in that matter, on condition that the things forfeited should be given to the Hospital of St. John the Baptist outside the East Gate.

Space fails us to deal with the many other sections into which this delightful book is divided, but we warmly recommend it to anyone who wishes to have a complete view of the life of his forefathers in the Middle Ages.

I. *A Medical Dictionary.* By W. B. DRUMMOND, M.B. Edin., F.R.C.P. Edin. London: J. M. Dent and Sons, Ltd. Pp. 625. Price 10*s.* 6*d.*

II. *A Short Italian Dictionary.* By ALFRED HOARE, M.A. Vol. I., Italian-English. Cambridge: At the University Press. 1918. Pp. 443. Price 9*s.* net.

I. THE title of this volume is a misnomer in that the volume is much more than a dictionary, being intended by the author to supply (1) information concerning our advances in medical knowledge which every inquiring mind desires; and (2) materials for supplementing the doctor's advice so that his directions may be carried out more faithfully and intelligently. Under the former category come a series of illustrated articles on Anæsthesia, Antiseptics, Bacteriology, Eugenics, and the like; under the latter, others on Athletics, Bandaging, Cooking, Ventilation, and so forth. We have found in a series of articles, chosen at random, the information in each case clearly and attractively written, and in most cases well illustrated. The four beautiful coloured plates of chicken-pox, rubella, measles, and scarlatina, from the "Hand-Atlas of Diseases of Children," should prove specially useful, as well as the manikin in five layers, but all the illustrations reach a high level. We congratulate Dr. Drummond on a book which can be consulted by the non-medical inquirer, and which may be of use to the medical man when required to present a topic to a lay audience.

II. This Italian dictionary is an abridgement of the author's well-known quarto dictionary which was published some three or four years ago, and for ordinary purposes of translation the smaller dictionary will be found as useful as the larger one. It may be remembered that the quarto dictionary had appended to it a short English-Italian vocabulary, and this vocabulary is to be extended until it is as large as the abridged Italian-English dictionary to which it will form a second volume, the whole work covering the needs of the translator completely. There has long been need for a dictionary which would serve both Italian and English purposes, and we can recommend thoroughly Dr. Hoare's work, anticipating that the second volume will be as good as the first. A prefatory synopsis of the conjugation of the Italian verbs will be found very useful. Included in a list of strong, irregular, defective, and other difficult verbs are all the verbs of the third conjugation, so that the student may know which of the two models is to be followed.

The Dispensatory of the United States of America. By J. P. REMINGTON, Ph.M., F.C.S., and HORATIO C. WOOD, Jr., M.D. Twentieth edition. London and Philadelphia: J. B. Lippincott Company. 1918. Pp. 2010. Price £2 10*s.*

IT is 11 years since the appearance of the last edition of this encyclopædic work and 85 years since it was first published, during which time it has doubled its number of pages and nearly quadrupled their printed content. The original object of the Dispensatory was "to present an account of medicinal substances in the state in which they are brought into the shops, and to teach the modes in which they are prepared for use." This scope still holds good, although with the development of therapeutic agents the actual "substances" are now very different from those at first contemplated, and bacterial products and serums, as well as hundreds of synthetic remedies, are fully dealt with. This has necessitated a complete rewriting of the text, for which purpose the two editors in chief have called in the help of professors of chemistry, pharmacy, and botany, and a director of a research laboratory, who are now associated with them on the title page. The whole is based upon the newest editions of the U.S. and British pharmacopœias and the U.S. National Formulary. On both sides of the Atlantic it will be found to be an inexhaustible mine of accurate information.

THE LANCET.

LONDON: SATURDAY, AUGUST 3, 1918.

The Principles and Ideals of Medical Education.[1]

SIR GEORGE NEWMAN, Chief Medical Officer and Principal Assistant Secretary of the Board of Education, has addressed to Mr. H. A. L. FISHER, President of his Board, a Memorandum on medical education in England, which is alike a valuable résumé of the subject and a repository of useful suggestions for future developments. Grants in aid of medical education were first made by the Board of Education in 1908, and from that date the Board has taken official cognisance of what is being done at the various medical schools to which assistance has been given. This cognisance has consisted of periodical visits, made by Sir GEORGE NEWMAN in conjunction with distinguished medical visitors, and on the resulting advice the grants have been assessed. Sir GEORGE NEWMAN has therefore been able to compose his Memorandum out of the fullness of personal knowledge acquired by discussion with local education authorities and reinforced by high assistance. The Memorandum is introduced by a section setting out the nature of medical education in the country at the present moment, in the course of which the educational functions of the General Medical Council are reviewed, and the principles set down upon which medical schools have been recognised as fit subjects for Grants in Aid by the Board of Education. That the scope and necessity of these Grants may be fully understood, the succeeding sections of the Memorandum have been written, for it is really the justification of a public department for spending money upon sectional training. And the justification is complete.

The 12 chapters which follow the introduction subdivide the subject of medical education in an orderly manner. First the functions of the medical practitioner are considered, as well as the conditions of medical practice, and the place which a University education should have in medicine. These general matters are discussed with clearness, and the way in which the information is brought together should make plain many questions which have hitherto been found difficult, because debates upon them are so often loose, indefinite, and inconclusive. Coming next to the study of the preliminary sciences, chemistry, physics, and biology, Sir GEORGE NEWMAN discusses in Section 4 of his Memorandum the divergences of view among educational authorities. For upon two important issues—namely, what should be the "content" of each subject as an adequate preliminary to medicine, and when in the student's curriculum should each subject be introduced—no two educational experts ever seem to be wholly in accord. The question of "content"—i.e., of the syllabus or range of study to be required of the student—has been settled on a more or less comparable plan by the various universities of the country possessing a medical faculty, but this must not be taken to mean that all the universities and corporations can or do provide equal facilities for the education of their students according to a common design. It is exactly here that the Board of Education can play a most valuable part in helping to provide the means whereby education can be levelled up, and to supply some of the necessary information in a clear form has been the direct object of the Memorandum. Turning to the second issue, which is concerned with the time in the student's education at which the preliminary scientific subjects should be attacked, relegation of these subjects to the student's career at a secondary school is recommended. While improvement has been made in the teaching of these subjects in certain medical schools, the advance in medical knowledge has in its turn shown more intimate relations between the subjects and practical medicine, so that the ground which the teacher has to cover is being rapidly extended, while the outcry against an overloaded curriculum becomes yearly more distinct. The perplexing position is thus reached that, with regard to the amount and standards of preliminary science to be acquired, while the medical school is the ideal place to learn the subjects, having regard to their later application, at this ideal place there is no longer opportunity for their acquisition comparable to the opportunity that could be offered at a good secondary school properly equipped. Sir GEORGE NEWMAN comes to the following general conclusions. He considers that the foundations of chemistry, physics, and biology for the medical student should be laid in the secondary schools in a thorough grounding in inorganic chemistry, mechanics, elementary physics, natural history, and botany. In some of these schools, he points out, it would be practicable in two years to cover the ground of all preliminary science ancillary to medicine, making it unnecessary for the student to devote any time at the medical school to study of these basic sciences. While indicating that in this way it would be possible both to unload the medical curriculum and yet give to the student a better start than formerly, the Memorandum recognises that such schools are not to be found in all divisions of the United Kingdom, and in so doing indicates one of the chief difficulties ahead. But while relegating the preliminary sciences to the secondary schools, Sir GEORGE NEWMAN'S further conclusions on the subject provide for linking scholastic studies up with medical studies proper, finding that there is no visible continuity throughout medical education between subjects and departments. In short, the professor of physiology may know nothing of the work of the professor of pathology, while the essence of medical education is that the student should see in pathology an altered physiology. Our educational authorities

[1] Board of Education. Some Notes on Medical Education in England. A Memorandum addressed to the President of the Board. By Sir George Newman, K.C.B., M.D., F.R.C.P., Chief Medical Officer and a Principal Assistant Secretary of the Board of Education, and Medical Assessor to the Universities Branch of the Board. London: Published by His Majesty's Stationery Office. Cd. 9124. Price 9*d*.

should realise that, when any considerable mass of teachers and students can ask seriously, "Why do we learn, or why do we teach, just these things and up to just this point?" then the system employed has failed in logical reason and sequence.

The remaining sections of the Memorandum deal with the position and conditions of study in the medical curriculum of anatomy and physiology, which lead in their turn to the study of pathology and of the clinical subjects, surgery, medicine, gynæcology, and therapeutics. The defects in the curriculum here are as frankly pointed out as the value of the work which is done is acknowledged. The criticisms come under four heads, to one of which, the insufficient coördination between subjects and departments, we have alluded to; the others are:—Default from university standards in the medical teaching; Absence of a proper association between medical education and medical research; and Insufficient organisation of the post-graduate study of medicine. Sir GEORGE NEWMAN is, above all things, a practical and constructive critic, and is not afraid to suggest remedial action. From the four principal defects which he sets out, "two fundamental necessities," he says, "emerge; the need of further financial assistance and need of guidance and direction." He holds that the old-fashioned way, the literally mediæval way, of running the medical education of the country out of the students' fees for tuition must end in failure. "It is impossible, to-day," he says, "to teach medicine as it ought to be taught out of students' fees or uncertain endowments. The result is that medical education and research are starved." We entirely agree with him, and agree also with his corollary, that if financial assistance be the first requirement, the next requirement, a further and collateral necessity, is wise, economic, and purposive outlay of any funds provided by the State to meet the proved needs. Such money will be public money, it will be disbursed, if it is granted, in aid of the improved standardisation and the detailed reform of medical education, and with regard to the allocation of such grants the medical profession alone cannot expect to have the disposing voice, though it can and must demand to be consulted in circumstances making it likely that medical views will receive proper weight.

The Memorandum is not only a long one but very closely written. We have only attempted here to indicate its contents and outline the more controversial sections at the beginning of the document. We urge our readers to obtain and read the Memorandum.

Malaria in England.

DURING the summer and autumn months of last year 178 cases of malaria of indigenous origin occurred in the south-eastern counties of England. The form of disease in each case was benign tertian of not very severe type, and no single death resulted. Of the total number of cases 136 were men serving in the Army, 19 in the Navy, and 23 were in civil life. Only in two districts—namely, the Isle of Sheppey and the neighbourhood of Sandwich—was there anything which could properly be called local prevalence. As an actual cause of sickness the outbreak was therefore almost a negligible factor. These are the facts set out by Dr. G. S. BUCHANAN, assistant medical officer to the Local Government Board, in his introduction to a volume of papers just issued by the Board as a Special Report (New Series, No. 119). The larger part of this introduction, dealing with the principles of preventive action, we give in slightly abridged form on another page, as well as the headlines of the various papers, but we should like to draw special attention here to Lieutenant-Colonel S. P. JAMES'S paper, entitled "Practical Points in the Study of the Disease and its Diagnosis," as we find in it a practical summary setting out clearly and logically the principal facts of malaria, its parasitology, diagnosis, treatment, and practical prevention, in a way which will meet a need long felt by those at home who have not been brought in actual contact with the problems of malaria. In spite of the mildness and comparative smallness of the outbreak Dr. BUCHANAN regards the appearance of indigenous malaria as disquieting in view of the fact that in old days when ague was common in this country there were often epidemic years, particularly those with hot, dry summers, in which its prevalence became very severe. Anophelines have been shown[1] to occur practically in any part of England where conditions are favourable to their breeding, and an increasing number of men returning from the Eastern campaigns are carriers of the malaria parasite. Exigencies of military service, or the termination of the war, may at short notice provide all the material necessary for intensive local infections. The most important question now is to know what methods of protection have been decided upon by the two Government Departments chiefly concerned, and these are epitomised by Dr. BUCHANAN. An anti-mosquito campaign such as has been attended with striking success in Panama and the Sudan is regarded at present as impracticable in this country. Segregation of the human carrier in special hospitals is possible enough for the men actually suffering from malaria, but to do the same with convalescents would entail serious loss of man-power and grave hardship on the men. The Army authorities rely, therefore, upon getting results largely equivalent to those theoretically obtainable by segregation by systematising the method of curative administration of quinine. These and other matters are ably set out in the special report. Obviously the first requisite is the dissemination of accurate knowledge both of the disease and of its causes, as well as of the administrative measures so far shown to be desirable. This purpose the volume admirably meets.

[1] The Trustees of the British Museum (Natural History), Cromwell-road, London, S.W., have just issued a map showing the known distribution in England and Wales of the anopheline mosquitoes, with explanatory text and notes, by W. Dickson Lang, M.A., assistant attached to the Department of Entomology (price 2s. 6d.).

Annotations.

"Ne quid nimis."

CURRENT MEDICAL POLITICS.

THE Annual Representative Meeting of the British Medical Association which was held in London last week was not dominated, as in 1917, by any one burning question of medical polity. The activities of the Central Medical War Committee were taken for granted, the only resolution bearing upon its work expressing the desire that Government assistance should be welcomed towards its expenses, short of making the Committee subservient to War Office instructions. After full consideration given to the scheme drawn up by the Council of the Association the desirability of the establishment of a Ministry of Health was assumed by the meeting, the Council being called upon to coöperate with the Royal Colleges and other medical bodies or corporations interested in the matter in pressing the formation of such a Ministry upon the Government. The immediate urgency of legislation in this direction was alleged in a resolution of the meeting, which is being forwarded direct to the Prime Minister and the Home Secretary. We note in this connexion Sir George Cave's statement in the House of Commons, reported by our Parliamentary Correspondent, that the Committee of Home Affairs hopes shortly to get its proposals for a Health Ministry into shape in a non-contentious form.

The representation of the medical profession in Parliament was debated, revealing a wide divergence of view in regard to principles. The Council of the Association, as such, gave the meeting no direct lead, but a unanimous resolution was passed to the effect that the medico-political education of the profession should be improved in order to secure for medical candidates the medical vote at University elections. But in regard to Parliamentary representation in general opinion was divided between a policy of securing candidates who should adopt the political tenets of one or other of the great parties whilst pledging themselves to represent medical interests as they arose, and the other policy—frankly regarded by many as Utopian—of returning to Parliament one or more candidates as direct representatives of the medical profession. The opposite view was strongly expressed that medicine has no need for representation of this kind in Parliament, inasmuch as the medical profession, speaking as a united force to the nation on any matter, would ensure its voice being heard without Parliamentary representation, on the principle that when the public listens Parliament is obliged to act. The distinction between the representation of medicine, as a science whose development is of the first importance to the public, and the representation of medical interests in the conduct of public affairs was not very clearly brought out at the meeting.

The relations of the medical profession to the certified midwife came up on a series of recommendations from the Council. The Association had one voice in opposition to any measure calculated to place the practice of normal midwifery solely in the hands of the midwife, or to commit to her sphere antenatal work other than advice on general domestic hygiene. It was laid down at the meeting that any further diminution in the practice of normal midwifery by the registered practitioner would result in the loss of experience necessary to deal with abnormal cases. The transference of the conduct of normal labour to the midwife has already gone a very long way, quickened but not started by the war-time conditions. The Association foresees that the large increase in the number of women medical students is likely in the near future to provide a sufficiency of practitioners to meet the whole needs of midwifery, as well as of antenatal and postnatal care and treatment. We are not ourselves aware of any experience justifying the belief that the woman practitioner is likely to devote more attention to normal labour than the man. A resolution, which was largely but not unanimously supported, expressed the opinion that the private medical practitioners in any locality should have the clinical supervision of the midwives' practice; and we think that the meeting hardly realised the extent to which the Local Government Board is already aiding the midwifery service in rural areas under the supervision of the medical officer of health or of deputies appointed by him. We have referred but briefly to some of the more important topics discussed at a business-like meeting.

TRANSIENT HEMIPLEGIA.

IN another column of this issue will be found a clinical note, by Dr. H. H. Mills, on a case of transient hemiplegia, which presents certain features of interest. The patient, a young woman of 28, had a sudden attack of apparently complete left hemiplegia, which lasted for an hour or two, is said to have disappeared thereafter, began again on the same day at an hour not specified, and disappeared during Dr. Mills's visit in the evening. It came on once more for about a quarter of an hour during the night. Some 10 months previously the patient had complained of "creepiness," numbness, and heaviness of the left limbs for about three days. The Wassermann test in the blood was negative; the cerebro-spinal fluid was not examined. Transient hemiplegia is a not very infrequent neurological condition, and may be due to a variety of causes. In the first place, it is often stated to be caused by a temporary ischæmia in some cerebral area due to local spasm in the artery or arteries of supply. The possibility of cerebral seizures due to such arterial spasm has apparently been accepted widely, but it is not yet clear whether a condition of intermittent claudication occurs in cerebral vessels analogous to that of peripheral vessels. Dejerine's "intermittent claudication of the spinal cord" remains an hypothesis. Sir William Osler grants the occurrence of cerebral arterial spasm only in cases of hyperpiesis or of well-marked cerebral arteriosclerosis. Dr. Mills's case is not stated to have had either of these pathological conditions. Dr. O. K. Williamson, however, believes that arterial spasm may occur without signs of these, arguing from the phenomena of migraine. Now, secondly, there is a similar uncertainty in regard to the latter condition. It is known that temporary local motor weakness may accompany an attack of migraine, although such weakness as a rule lasts only for minutes, and in any case the sensory symptoms of migraine are much more prominent and, in fact, constant. Dr. Mills's patient does not appear to have had any of the usual sensory phenomena of migraine, while the paralysis was more absolute than is seen in that "neurosis." But there are objections to the local arterial spasm or

local vasomotor change theory of migraine, as was clearly pointed out by Gowers. It should always be borne in mind that some of the phenomena of migraine are "positive," in Hughlings Jackson's sense, and others "negative." Irritative and paralytic phenomena cannot both be caused by the same morbid process at the same time, yet local arterial spasm is invoked to explain both sets of symptoms. A third possible cause of transient hemiplegia is cellular exhaustion after an epileptic cortical discharge. A fourth condition is associated with infective states such as measles and other fevers, where transient motor paresis has been not infrequently found. Again, in the *état lacunaire* described by Pierre Marie and his pupils—a "subacute vaginalitis" of the sheaths of small cerebral vessels—a transient paralysis of some hours' duration may follow an ictus not associated with loss of consciousness. Still another possibility to be envisaged is that of disseminated sclerosis, which may certainly begin as a hemiplegic variety, with none of the so-called classical or cardinal symptoms. In this connexion the previous unilateral paræsthesiæ of three days' duration in Dr. Mills's case are of considerable significance. Transient paresis in disseminated sclerosis is often in the foreground of the clinical picture. The negative Wassermann test in the blood is of importance, needless to say, yet examination of the cerebro-spinal fluid in so interesting a case might have been helpful. In a few cases of meningitis circumscripta serosa there has been sudden onset of paralysis, which has as suddenly disappeared after lumbar puncture. Reference may be made to a point of minor interest in Dr. Mills's case. The hemiplegia was on the left side, but the patient had much impairment of speech, as opposed, it may be gathered, to articulation, and "knew what she wanted to say but could not say it properly." We are not told whether the lady was left-handed; this, however, might be ascertained, for a crossed aphasia is of such clinical rarity and interest that every case deserves full investigation.

A WAR STUDY OF BRAIN SURGERY.

Mr. Harvey Cushing records in the April number of the *British Journal of Surgery* a detailed study of the treatment of wounds met with involving the brain and its enveloping structures. This is a valuable communication, since the methods adopted by him and his team of workers have resulted in a reduction of the mortality of dural penetration cases—133 in number—from 54·5 per cent. for the first 44 cases to 28·8 per cent. for the last 45 cases. It seems that there remains still, after three years, less unanimity of opinion as regards the principles of treatment of cranio-cerebral injuries than of any other type of wounds, and a summary of Mr. Cushing's methods will therefore be of general interest.

The material analysed is composed of 250 cases; of these, 10·1 per cent. were scalp wounds, 24·6 per cent. involved cranium as well but with intact dura, 60·7 per cent. had dural penetration, and 4·5 per cent. were massive or bursting fractures. The operative procedure adopted by the writer consists essentially in the removal *en bloc* of the area of bony involvement, the withdrawal by suction through a soft catheter of the devitalised cerebral tissue lining the track, and the extraction of bone fragments with the least possible increase in the trauma already produced. A classification of cases is adopted, less in accordance with the site or character of the cranial involvement than with the seriousness of condition of the cranial contents. One can only touch here upon a few of the interesting points detailed by Mr. Cushing. He warns us against underestimating the possible seriousness of scalp wounds, especially if situated on the longitudinal sinus. In those cases where there is depression of the inner table trepanation is indicated, of course, but recovery is often hastened by incision of the dura, the dangers of infection, it is stated, being less than has hitherto been feared. Wounds with laceration of the dura and cerebral contusion are favourable cases, in spite of the fact that the meninges have been torn; even though the scalp wound may be grossly contaminated, there is no immediate risk of intracranial infection, since the more or less intact mosaic of bone fragments intervenes, and extrusion of brain substance is uncommon. More serious are those cases, 39 in number in this series, where fragments are widely indriven; often also cerebral protrusion occurs. Most of these cases are wounds over the parietal area. An interesting feature in these cases is the progressive nature of the symptoms recognised by the patient who, after return to consciousness, is aware of weakness of one leg, or leg and arm, sometimes succeeded by paralysis or spasticity. When the ventricles were penetrated by a missile death occurred in all cases, probably due to early infection of the cerebro-spinal fluid. Not uncommonly the projectile lodges actually in the ventricle. In other cases in this series, where the ventricle is not penetrated, the mortality was 54·3 per cent., infection again playing the chief rôle.

Mr. Cushing, in a final review, holds that the clinical histories of the 219 operation cases have clearly shown a large number of the recorded fatalities to be avoidable—not only by the employment of a still more perfect technique, but by its more prompt application. He is in favour of operating on these cases in the earlier stages and eliminating, as far as possible, the delay in transit for even the more serious cases. The success of his methods certainly adds weight to these opinions.

THE ROUTINE USE OF SPINAL ANALGESIA IN GYNÆCOLOGY.

SPINAL anæsthesia has proved so useful in operations below the level of the umbilicus that it is not surprising to find gynæcologists are using the method more and more. Up to the present time, so far as we are aware, this method of anæsthesia has hardly been regarded as sufficiently free from risk to be employed as a routine procedure in all cases; but the series we publish (p. 141), from the clinique of Professor Dobbin at the Kasr-el-Aïny Hospital, Cairo, proves that it can be used, at any rate in Egyptian women, in all varieties of gynæcological operations with success and safety. A total of 1891 operations under spinal anæsthesia is sufficient to warrant us in regarding as trustworthy such evidence of the advantages and disadvantages of spinal anæsthesia in this class of case. From the conclusions drawn by Dr. Mahfouz—and the facts he adduces certainly warrant his conclusions—the advantages are many and the disadvantages few. The small number of cases in which complete or partial failure to produce analgesia occurred can almost all be explained as due to errors in technique, and the series is very remarkable for the infrequency with which dangerous symptoms occurred, either during or after the operation. The author remarks that the woman may find the lithotomy position distressing while she retains consciousness, but this is readily got over by putting the patient lightly under the influence of a general anæsthetic before the intraspinal injection is given, and if necessary keeping her sufficiently under to prevent her being conscious of what is actually happening. The plan has already been adopted by some gynæcologists. Very little general anæsthetic is required when the patient is under the influence of stovaine, and it is quite easy to keep her sufficiently under its influence to annul entirely any mental shock consequent upon her exposure in the lithotomy position or upon the discomforts of the extreme Trendelenburg. position. It is urged by some of its

adherents that spinal anæsthesia does away with the necessity for the Trendelenburg position; but this is not so; it is true that spinal anæsthesia gives complete abdominal relaxation, but the facilities for carrying out such an operation as an extended abdominal hysterectomy afforded by the Trendelenburg position are so real that it is the custom of many gynæcologists to invert their patients even when spinal anæsthesia has been employed. Some operators elevate the table as soon as the spinal injection has been given, others—and this, in our opinion, is the best plan—wait some 15 to 20 minutes before doing so. It is especially in such operations as extended abdominal hysterectomy for cancer of the cervix uteri that the combined method of spinal and general anæsthesia is so useful. The performance of the operation is facilitated, the shock lessened, and the convalescence of the patients rendered quicker. Dr. Mahfouz's paper is a valuable contribution to our knowledge of spinal anæsthesia, and Professor Dobbin's excellent results should do much to commend the method to gynæcologists.

THE hearing of the action brought by four members of the medical staff of the Coventry Provident Dispensary against the British Medical Association and certain of its officers was concluded on Tuesday last, when Mr. Justice McCardie, who was sitting without a jury, said that he would take time to consider his judgment.

IN answer to a request made by a county medical officer of health to the Medical Officer of the Local Government Board, the Registrar-General has arranged to supply to every medical officer of health for the year 1918, and in subsequent years, a statement of the number of deaths under one year of age in each sanitary area classified by legitimacy as well as sex. This is in addition to the statistical information already supplied to medical officers of health by the Registrar-General, and it is hoped that in this way further investigation will result into legitimacy of birth in relation to infant mortality.

THE death is announced of Dr. Frederick T. Roberts, consulting physician to University College Hospital and Emeritus Professor of Medicine in University College, London, which took place on July 28th, in his 79th year. Dr. Roberts, who was a Fellow of University College, London, and Hon. D.Sc. of the University of Wales, was the author of a text-book on the theory and practice of medicine, which was a standard manual for many generations of students. More detailed appreciation of Dr. Roberts's career will appear in a forthcoming issue.

AS we go to press we learn with regret the death of Mr. Henry Betham Robinson, Major, R.A.M.C. (T.), the well-known surgeon on the staff of St. Thomas's Hospital, London.

THE LANCET, VOL. I., 1918: THE INDEX.

OWING to the continued shortage in the paper-supply, the Index and Title-page to the volume of THE LANCET which was completed with the issue of June 29th have been printed separately, and copies have been supplied gratis to those subscribers who have, up to July 31st, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C.

REPORTS AND PAPERS ON MALARIA CONTRACTED IN ENGLAND IN 1917.

A SERIES of important reports dealing with the occurrence of indigenous cases of malaria in this country has just been issued by the Local Government Board in a volume described as New Series No. 119 (price 4*s*.). The papers include:—

Notes on Military Cases of Malaria contracted in England in 1917, from reports furnished by the Army Medical Department.
Naval cases of Malaria contracted in England in 1917, contributed by Deputy Surgeon-General P. W. Bassett-Smith, R.N.
Civil cases of Malaria contracted in England in 1917, by Lieutenant-Colonel E. Wilkinson, I.M.S.
Malaria: Practical Points in the Study of the Disease and its Diagnosis, by Lieutenant-Colonel S. P. James, I.M.S.
English Mosquitoes, by A. J. Grove, M.Sc.
Tables showing Recorded Observations of Anopheline Mosquitoes in England.
General Abstract from a Report to the Army Medical Department on the Mosquito Survey of the Aldershot District, by Captain A. C. Parsons, R.A.M.C.
Reports of Surveys of Certain Areas in England with Reference to the Occurrence of Anopheline Mosquitoes, 1917, by A. J. Grove, M.Sc., and by Mrs. A. Macdonald.
Map showing the Localities in which Anopheline Mosquitoes have been Recorded. Prepared at the British Museum (Natural History) by direction of the Trustees.

The reports are introduced by Dr. G. S. Buchanan, assistant medical officer to the Local Government Board, with a comprehensive review of the present position of indigenous malaria and the principles of preventive action. With the former we deal elsewhere, and the following is a summary of the latter.

The Principles of Preventive Action.

There are several different methods of malaria prevention the adoption of one or other of which depends upon the particular conditions to be encountered and the particular principle which it is decided to apply. It is essential to decide which link in the chain of infection is to be the main object of attack. A little antimosquito work, a loose and ill-considered system for detecting and reporting malaria cases, and a haphazard administration of quinine will not greatly help, and may be dangerous by giving a false impression of security. Certain lines of preventive action have been considered at conferences between representatives of the medical departments of the Army and the Local Government Board.

Antimosquito Work.

A negative proposition as regards anti-mosquito work must first be stated. In this country we are used to gnats and midges. We do not often talk of mosquitoes, and think of them as rare. The appearance of a disease which is known to be "mosquito-carried" thus at once suggests that it should be dealt with first and foremost by striking at its insect host. Attention is at once drawn to certain well-known anti-mosquito campaigns with their systematic method of drainage, petrolage, and the rest, which have been so effective against the mosquito-carried diseases—yellow fever and malaria—in Panama. The way in which for many years past such campaigns have practically banished all anophelines and malaria from places in Egypt and the Soudan is also well known. It has already been urged that similar methods should be at once organised and taken in hand, if not in the country generally, at least in places like Romney Marsh, Sandwich, and the Isle of Sheppey, where mosquitoes in general, including anophelines, are numerous and often in themselves constitute a considerable local nuisance.

On this matter it is necessary to point out that the undertaking of such anti-mosquito campaigns must not be considered as the only method likely to be effective under English conditions, or necessarily the best method. And in considering its practical aspects it will be well to refer to the inquiries as to the distribution and prevalence of anophelines in England contained or reported in these papers, and particularly to the accounts of the detailed mosquito-surveys. Consideration of these facts of distribution, of the habits which distinguish the anopheline from other mosquitoes, and of the nature of the work which has been found necessary in malarious countries where anopheline destruction has been effectively dealt with points to the conclusion that the task, even when limited to small areas, would be one of very considerable magnitude if it is to be done in such a manner as effectively to prevent risk of the inhabitants being bitten by anophelines.

Much the same applies to measures which merely aim at the temporary reduction in the numbers of anophelines in an area where they are relatively abundant. Such a reduction might perhaps be attempted administratively by treating the matter as a war emergency requiring special powers to be obtained and exercised. But this proceeding, if carried out on any scale in the areas principally concerned, would make demands on the supply of available labour and entail an amount of interference with agricultural work that ought

not to be asked for at the present time without much stronger evidence of its necessity than could at present be put forward.

While thus setting aside comprehensive antimosquito work as impracticable at present, it should be said that from many points of view it would be desirable that some exact experimental work on mosquito eradication under English conditions should be undertaken in suitable areas on a small scale. Moreover, minor measures can sometimes be taken for destroying mosquitoes or mosquito larvæ by individuals or by the military or local authorities; for example, the clearing of particular ditches or ponds close to dwellings or camps which are found to be prolific mosquito breeding-places, or the cleansing and whitewashing of cowsheds which harbour the adult insect. Provided that the limitations of such methods are understood and primary reliance is not placed upon them for dealing with local risks of indigenous malaria, such measures are all very good and deserve encouragement.

Control of Human Carriers of the Parasite.

Another root-and-branch proposal has been considered in connexion with the alternative plan of checking infection by control of the human carrier of the parasite. Broadly, this is a proposal for Army action to segregate those men who return from the Eastern war areas or elsewhere, having there been attacked by malaria; segregation in special hospitals in the case of those actually ill, and in special camps or convalescent establishments in the case of all who are convalescent from recent malaria or who are liable to relapse. To a large extent the first is already secured by the plan which for some time has been followed by the Army authorities. Men actually suffering from malaria, not only those returning direct from abroad but also those who have now been transferred to home service, are already treated for the most part in special military hospitals, with precautions where they are needed against mosquito infection. If they are treated in other hospital units and there is any risk of mosquito infection, the hospital ward is screened and other precautions are taken.

With convalescents, however, the case is otherwise. A large and increasing number of men who in the intervals of attacks are well or in fair health, though liable to relapse of malaria, cannot be segregated and kept from their proper Army work or from going on leave to their homes for long periods—perhaps for years. The impossibility of doing this without great loss of man-power and grave hardship to the men themselves is self-evident, and it may be added that even complete segregation of all men known to have had malaria would not meet the whole difficulty, as some men harbour the malaria parasite without being aware that they have had the disease.

The Army authorities rely upon getting results which are largely equivalent to those theoretically obtainable by segregation, by systematising the method of curative administration of quinine. It is aimed at giving this drug in such a way as to secure as far as possible the "disinfection of the infected," or in any case to obtain a great reduction in the period during which the blood of the malarial case would contain the parasite and also in the intensity of possible infectivity. The methods referred to have been the subject of various Army orders and arrangements. In addition, a special system has been adopted for dealing with malaria cases returning from Salonika. This system provides for the inspection of men of this group at the port of disembarkation by a medical officer who decides as to the necessity or otherwise of their immediate admission to hospital. Those for whom admission to hospital is not considered necessary are sent to their regimental depôts, where they are granted 30 days' furlough before returning to duty, and by means of a malaria card and other arrangements steps are taken to secure that any necessary treatment is continued.

"Malaria-suspected" Areas.

It may be anticipated that to the extent that the Army system referred to is continued and developed the risks of extension of indigenous malaria will be reduced to small and manageable limits. Looking to these considerations, it seems sufficient at the present time to limit any exceptional precautionary measures to certain particular localities which may be termed "malaria-suspected areas," selected on account of the appearance in 1917 of multiple cases of indigenous malaria or because of facts which show that in these areas a considerable concentration of possible human malaria-carriers coincides with an exceptional abundance of anophelines. The areas at present noted for such exceptional treatment as agreed upon between the medical departments of the Army and the Local Government Board are:—

Military Areas.	*Sanitary District Concerned.*
(1) Isle of Sheppey and Isle of Grain.	Sheerness Urban; Queenborough Urban; Sheppey Rural; Hoo Rural.
(2) Sandwich.	Sandwich Urban; Eastry Rural.
(3) Romney Marsh.	New Romney Urban; Lydd Urban; Romney Marsh Rural.
(4) Borden and Longmoor (Aldershot area).	Alton Rural; Alton Urban.

The selection of these areas has been arbitrary, and it is intended to extend them should experience show that this is necessary. Guidance will be obtained during the present year, first, by the experience in these areas themselves; secondly, by the information obtained as to the occurrence of any groups of indigenous malaria cases outside these areas; and, thirdly, by arrangements which have been made in the Army Medical Department for watching the concentration in particular camps or districts of men who have returned from eastern war regions.

While it is not in present circumstances considered essential to take steps to make malaria a disease compulsorily notifiable throughout the whole of England and Wales, it is important that in any district where a medical practitioner suspects malaria of indigenous origin he should at once communicate the facts to the medical officer of health of the district, or direct to the Board, and should utilise the facilities provided for examination of blood specimens.

Special Measures in "Malaria-suspected Areas."

The following arrangements are at present in operation, or in process of being made, in the areas specified above.

On the military side a medical officer with experience of malaria (acting under the general direction of Sir R. Ross from the Headquarters of the Army Medical Department) undertakes the expert and supervisory work necessary in connexion with camps and troops. With the aid of this officer, and by means of special instructions, steps are taken on the military side:—

(*a*) To detect malaria (new cases and relapses) at the earliest moment among men reporting sick or sent to hospital; giving systematic attention to all cases of pyrexia of doubtful origin or otherwise suspicious of malaria, and taking and examining blood films in all such cases. (*b*) To give any instruction and expert assistance necessary with this object to all medical officers at military camps or hospitals within the area, making systematic visits for this purpose. (*c*) To move hospital cases found to be suffering from malaria to one of the special malaria hospitals out of the area, or, if they are treated at local hospitals, to place them in wards which are properly mosquito-proofed. (*d*) In each camp within the area, to obtain a roll of men who have been in any malarious war area beyond France, or who state that they have had malaria within two years. Men on this roll to be specially examined weekly; to sort out those who are anæmic, or out of sorts without complaining of definite illness, and to detect any malarious condition or relapse. (*e*) In each camp within the area to have mosquito-screened hut or huts for malaria cases on the above roll, with a reserve of mosquito nets to be used in ordinary huts if this accommodation is exceeded; and to secure that appropriate quinine treatment is being given to all malaria convalescents. (*f*) To arrange that the military malaria medical officers will give the aid of their special knowledge where desired to civil medical practitioners, &c., within the area, to interchange information as to the prevalence of malaria with the medical officer of health, and to coöperate with medical inspectors of the Local Government Board who visit the area in regard to civil precautions.

On the side of *civil administration* the councils of the sanitary areas concerned are advised by the Local Government Board temporarily to add malaria to the list of diseases made compulsorily notifiable under the Infectious Diseases (Notification) Act, 1899, and to transmit to the Board at once information as to any newly notified case. Malaria has now been made thus notifiable in all the districts specified in the list above. Medical inspectors of the Board have conferred on the subject of malaria precautions with the medical officers of health, and local visits will continue to be made as necessary by them.

Through these central and local medical officers steps are taken on the civil side:—

(1) To assist medical practitioners or medical officers of civil hospitals in the area in the early detection of malaria cases. Blood films taken for this purpose and transmitted to the Local Government Board are examined and the result reported to the sender. The London School of Tropical Medicine has undertaken to assist in making these examinations. (2) To secure that any civil case of malaria is suitably treated in hospital or, if treated at home, is supplied with mosquito nets; receives necessary quinine treatment; is advised how to continue quinine so as to prevent relapses, and how to prevent other occupants of the house from becoming infected. (3) To obtain, through the medical staff of the county, a periodical examination of children at public elementary schools in the area, with a view to detecting cases of enlargement of the spleen or anæmia in which the possibility of malaria should be considered, and confirming the diagnosis by blood film examination. In this connexion the importance of inquiry as to absentees suffering from fever should be remembered. (4) To supply medical officers of health with information obtained from Army sources or otherwise regarding men who have had malaria and have returned to civil life or civil employment within the district. (5) To arrange that medical officers of health coöperate with the military malaria officer who has expert charge of the area as regards the camps and troops therein.

Conclusion.

The appearance of indigenous malaria as a consequence of war conditions in regions from which the disease has long been absent is not special to England. Civil and military cases in small numbers, which were comparable to those in England in 1917, were reported during the same year from certain parts of northern France. Close attention has lately been given by an inter-departmental committee, presided over by the Director-General of the Medical Department of the Royal Navy, to the occurrence of malaria in 1917 among passengers arriving from West African ports.

Correspondence.

"Audi alteram partem."

THE LATE RICHARD GRAINGER HEBB.

To the Editor of THE LANCET.

SIR,—I regret that the only notice of the death of the late Dr. R. G. Hebb which has appeared in THE LANCET should consist in the bare record of the fact. I know you will permit me, even at this late date, to pay some tribute, inadequate though it must be, to his memory. To all the men who have worked at Westminster Hospital during the past 38 years Dr. Hebb, consulting physician and physician-pathologist to the hospital, stands out as a unique personality. To us Dr. Hebb has meant pathology personified. Year after year, week in, week out, whatever changes might happen in the rest of the hospital, when not in his out-patient department or in the wards, he was always to be found in the pathological clinical laboratory or in one of the rooms of that department. To some of the students in their third year just entering into hospital work Dr. Hebb's manner may have seemed somewhat cold, but when they had passed through his classes in morbid histology and clinical pathology, and, better still, had had the great privilege of working under him as clerk in the post-mortem room, all became his devoted followers. Later, as resident officers in the hospital, Dr. Hebb's room was the resort where they always went with the problems that perplexed them and to talk over the physical signs and the various symptoms which they could not fit in with any description in the text-books. There from his vast experience they gained what they sought. For he was a physician-pathologist. He knew the patient as a clinician, and through all the years he was constantly verifying or disproving diagnoses in that place where errors cannot be complacently talked away. And therefore he habitually saw through clinical signs to the underlying pathological cause.

There have been few pathologists like Dr. Hebb. There will be still fewer, for he *lived* for pathology. He left no time for anything else; he cared for nothing else. He never laid himself out to gain private practice. He took part in no controversies, with the result that his true worth was scarcely known to anyone outside Westminster Hospital. Nevertheless, the offices he held and the posts he filled show that the range of his activities was far from limited.

Of all the memories that crowd upon an old Westminster man one stands out most vividly. It is 12 o'clock on any Wednesday morning. The men have hurried up to the weekly pathological demonstration—I say hurried, for only the bravest, or rather only the most obtuse, would venture to be behind time—and as Big Ben booms out the first stroke of the hour the door of Dr. Hebb's private room opens and the master of the situation walks to the table where the past week's specimens are arranged, waiting for that illuminating commentary which he knew so well how to fix in the memory of his listeners by caustic asides. This was the most dramatic moment of our Westminster week. It is no wonder that men interrupted whatever they were doing and hurried off so as not to lose one moment of that instructive hour. When in later life these men came up to London from the country, or home from the ends of the world, one of the great centres of attraction was this Hermit of Pathology. Even amongst the men who admired and valued his intellectual vigour, only few knew the heroism of those last years when, suffering from such pain as would have incapacitated many a younger man, his sense of duty held him unfailing to his work.—I am, Sir, yours faithfully,

Devonshire-place, W., 25th July, 1918. ARTHUR EVANS.

THE TREATMENT OF FUNCTIONAL NERVOUS DISORDERS IN THE ARMY.

To the Editor of THE LANCET.

SIR,—In your issue of July 20th you publish a request that medical men who are now being called up to serve with the R.A.M.C. should send in their names to the Director-General if they are desirous of undergoing a special course of training and of undertaking therapeutic work in functional nervous disorders. The enormous strides which have been made during the war in the treatment of these disorders, and the increasing recognition that the mental factors of strain and anxiety are primarily responsible for so many of the minor ailments met with in general practice, should surely attract an adequate number of applicants. The need for a special course of training, by means of systematic lectures and clinical demonstrations and instruction, is emphasised by the fact that different cases of functional disorder require different methods of treatment, and that electricity, manipulation, isolation, and the more purely psychological methods of analysis, suggestion, and hypnosis each have their value in appropriate cases if their limitations, their uses, and abuses are clearly recognised. The most successful medical officer is he who has learnt to select the particular treatment best fitted for each case, and who realises that he must familiarise himself with the different therapeutic methods. These can be learnt only by instruction in the hospitals which have been so successfully established throughout the kingdom for the treatment of functional nervous disorders.

I am, Sir, yours faithfully,

July 26th, 1918. M.

THE FUTURE OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—Thanks are owing to THE LANCET for bringing together the three thoughtful papers on this subject in the issue for July 20th. Without subscribing to any visions of advanced "socialism"—that half-witted offspring of ignorance and envy, and parent of decay—one cannot conceal from oneself the assurance that the war has hastened the recognition of a new "natural right of man"—viz., *the right to an equal chance of health* and of its inevitable corollary, the imperative necessity for a reorganisation of medicine to accord with it. That such a reorganisation must include a unification of direction and a status of sufficient authority needs no argument. All unbiased opinion demands a Ministry of Public Health with a Minister of Cabinet rank. This is already much overdue.

In framing any scheme for it, certain obvious defects in existing medical conditions and certain essentials of reform must be borne in mind.

Certain Existing Defects.

1. Preventive medicine is not yet independent of hindering local interests. It can only be so freed by becoming a whole-time State service.
2. Medical education is still in the hands of financially interested corporations, to the detriment not merely of medical training proper, but still more so of that preliminary general training of the mind which counts for so much in the making of the practitioner. A uniform State qualification with compulsory adequate minimum of general education is urgently needed, and medical education should be properly subsidised by the State—probably as part-time State service.
3. Something should be done to give the less-well-off equal advantages to those enjoyed by the wealthy and the poor. At present these advantages are denied them.
4. In the Insurance Act the evil principle of the control of a highly skilled industry by insufficiently trained minds was introduced. This must be remedied.
5. The financial *saving capacity* of the medical profession is ridiculously inadequate. A man doing such valuable public work as a doctor has a right to expect that his earnings will maintain himself, his wife, and children in health, pay for education, and provide for his and his wife's old age or for his family's support in case of his death or complete disablement. How many realise such expectations? Why, also, should medicine bear the greatest part of the burden of the medical charity of the nation?

Certain Essentials of Reform.

1. The new Ministry must control the whole of medicine. The Navy, Army, and Colonial Medical Services should certainly come under it. We must know in peace our liabilities in war, provide for them, and, as a profession, organise them.
2. Medicine must be controlled by adequately trained minds, and the Minister must be a medical man, since such alone can properly voice the medical needs of the country.
3. Except in such instances as the Navy and Army administrations and the Public Health Service, whole-time service must be restricted to administration. Those hopeful souls who think medicine could continue to flourish under whole-time conditions of service all round, however learned they may be, have not studied either history or human nature. Part-time State service for the great bulk of the profession is probably the most practical solution of the problem of State control.

4. Free choice of doctor by patient and patient by doctor is enormously important, as the chief means of maintaining the very peculiarly human relationship of doctor and patient, so vitally essential to getting the best out of medicine.

5. The labourer is worthy of his hire. Adequate pay and pension must be insisted on. It should be borne in mind that reluctance to press for these is far more often due to cowardice than to generosity.

6. "Leave" to recruit body and mind must be assured.

7. "Study-leave" to bring every man up to date periodically must be provided.

A Warning.

Whatever happens, the mere extension of the Insurance Act conditions to the entire profession must be resisted "to the last ditch." It is manifestly the desire of certain trades unionists to bring the medical profession into subjection to the "working classes." No one has a greater respect than I have for the "knights of labour," where indeed they are "knights." We have all felt for the men who have gone out to the war from the ranks of "labour" and returned to our care in hospital, something far more than wonder and gratitude, what one may call without affectation an ineffaceable affection; but with what feelings can we regard the men, safe at home, who have made of their country's dire peril a financial opportunity, whose callous disregard of their fellows in the trenches has inspired thinking men with contempt and detestation. Hands so unclean must not control the helm of national health.

I am, Sir, yours faithfully,

Exeter, July 21st, 1918. W. GORDON.

Postscript.

It is idle for any political wirepuller to imagine he can either bribe or bludgeon English medicine into any course it disapproves. The Insurance Act was based on such a misconception and it has failed. If the whole-hearted service of the profession is to be gained over for the nation in peace as it has eagerly given itself in war it must be under terms of service both equitable and enlightened. What is fairly due to its vast importance and responsibilities, to its arduous and highly-skilled labour, must be fairly met. But also, and vastly more important, its control must be in the hands of adequately trained minds, its mental and moral equals. We medical men do not care a straw from what class a legislator comes—observation and history alike convince us that the makers of England have come from her People in the broadest sense—but we care a great deal that those who control the progress of the physical welfare of the nation shall be men of trained intelligence and unquestioned probity. The profession which has been second to none in self-sacrificing patriotism in this unequalled war is not going to bow to the dictates of the Bolsheviks of Coventry.

The most important utterance in the discussion on Sir Bertrand Dawson's able paper was that of Sir Robert Morant, who said: "The medical profession should get to work to decide as to the particular characteristics the scheme should possess." What is now, therefore, necessary to bring matters to a head is the appointment of a committee of the profession, representative of every considerable section of its work, to draw up a definite plan for a reorganisation of its activities. Such a plan would be neither political nor protective in any real sense, but just as scientific and far vaster in scope than any proposals for the prevention of syphilis or the cure of tuberculosis. The personnel of the committee should be such as to command alike the confidence of the public and of the profession.

The proper body to call such a committee into existence must be a wholly non-political and recognisedly scientific body, representing already all important scientific medical activities. The Royal Society of Medicine answers to that description.

July 25th, 1918.

"TRYPAGAR."

To the Editor of THE LANCET.

SIR,—In his article in your issue of July 27th on a new medium for Pfeiffer's bacillus which he calls "trypagar" Dr. John Matthews refers to a medium composed of Douglas's trypsin broth and agar described by Captain S. R. Douglas in an article in THE LANCET of Oct. 10th, 1914. As we had always believed that the name "trypagar" was our own invention for another medium, I turned up this article and found that Captain Douglas does not use it. Had he wished to give his medium a name he would probably have called it "trypsagar." In the communication by Lieutenant-Colonel M. H. Gordon and myself to the *British Medical Journal* of Nov. 18th, 1916, we gave the name trypagar to the medium we therein described for the meningococcus, and which consisted of Douglas's trypsin broth and extract of peaflour combined with agar. The name "trypagar" was supposed to represent "try" for Douglas's trypsin broth, "p" for peaflour extract, and "agar," of course, for the agar. Sir Walter Fletcher suggested that we should call it "trypsagar," using the "ps" for the Greek ψ, until we pointed out that the "p" stood for the peaflour extract. Perhaps the difficulty would be best met by calling Douglas's trypsin broth agar "trypsagar," while retaining the name "trypagar" for the medium for which it was introduced—namely, trypsin broth containing pea extract and agar.

I am, Sir, yours faithfully,

T. G. M. HINE,
Major, R.A.M.C.

Central C.S.F. Laboratory, Caxton-street, S.W., July 29th, 1918.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions and donations to the Fund have been received during the week ending July 29th:—

	£	s.	d.
Dr. L. Gwillim Davies...	2	0	0
Mr. J. H. Frost	1	1	0
Cheltenham Doctors [1] ...	0	18	0
Mr. J. Gay French ...	5	5	0
Dr. Elizabeth Wilks ...	5	0	0
Dr. H. W. Arbuckle ...	1	0	0
Mr. Robt. Read	0	10	0
Dr. G. MacDonald ...	1	1	0
Mr. L. J. Giles	1	1	0
Mr. J. G. Atkinson ...	1	0	0

[1] Balance of Fund raised by Cheltenham doctors for hospitality to Belgian doctors (per Dr. G. A. Cardew). [2] Per Mrs. Scharlieb.
[3] Per Dr. N. Walker. [4] Per Dr. Des Vœux.
[5] Per Dr. Herbert Spencer. [6] Per Dr. A. A. MacKeith (Hon. Sec.).
[7] Per Dr. Cameron Kidd.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

INFLUENZA IN SWITZERLAND.—Our Swiss correspondent writes: "An epidemic of influenza, or *grippe espagnole* as it is called here, has been widely prevalent in Switzerland during the last two months. At the beginning of July the severity of the attacks suddenly increased and fatal cases are being recorded daily in many cantons, especially Berne, Basle, Lucerne, and Zurich. In Berne the civilian population has been attacked to one-fifth or more of its total number. At Château d'Oex 6 out of 250 English internés are reported to have succumbed to it, and among Swiss soldiers the official bulletin recorded 11,000 cases with 305 deaths down to July 15th. The American Red Cross has voted a sum of $100,000 to provide better accommodation for sick soldiers, a large hotel at Interlaken having been secured for convalescents. The symptoms are those generally associated with influenza, but of a severe type, pneumonia being a common complication. In canton Vaud notification has been made compulsory, meetings are forbidden, and no visits allowed to patients in hospital. The medical profession has not escaped, and a certain number of fatal cases are reported, among them Dr. Steiger, first assistant to Professor Eichhorst in the cantonal hospital at Zurich."

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue :—

Killed.

Surg.-Prob. J. J. A. Lord-Flood, R.N.V.R.

Wounded.

Lieut. S. Riddiough, R.A.M.C., attached Highland L.I.
Capt. A. J. Spuy-Vanger, South African M.C.
Capt. F. W. Schofield, R.A.M.C.
Capt. W. Hall, jun., M.C., Canadian A.M.C.

Previously reported Prisoner, now reported Wounded and Prisoner in German Hands.

Capt. E. H. Griffin, D.S.O., M.C., R.A.M.C.

Previously reported Missing, now reported Prisoners in German Hands.

Capt. W. F. Dunlop, R.A.M.C.
Major F. G. Lescher, M.C., R.A.M.C.
Lieut.-Col. H. B. Kelly, D.S.O., R.A.M.C.

Previously reported Wounded and Missing, now reported Prisoner in German Hands.

Lieut. G. V. W. Anderson, R.A.M.C.

Missing.

Capt. M. Donaldson, R.A.M.C.
Lieut.-Col. A. C. H. Gray, R.A.M.C.
Capt. E. H. Jones, R.A.M.C.
Major E. J. Tilbury, R.A.M.C.
Major A. M. Wood, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualty among the sons of medical men is reported :—

Lieut. W. K. Wallis, attached East Lancashire Regiment, killed in action, eldest son of the late Dr. J. A. Wallis, of Preston.

THE HONOURS LIST.

The following awards to medical officers for services rendered in connexion with the operations against Zeebrugge and Ostend on the night of April 22nd–23rd, 1918, are announced :—

Distinguished Service Order.

Surg. FRANK PEARCE POCOCK, M.C., R.N. (*Iris II.*).—By his devotion to duty he undoubtedly saved many lives. When *Iris II.* was hit he at once commenced tending the wounded, and as all the sick-berth staff were killed, had all the work to do alone. After the dynamo was damaged he had to work by candle and torchlight.

Distinguished Service Cross.

Surg. WILLIAM LITTLE CLEGG, R.N. (*Vindictive*).—Was in charge of the stretcher parties on the upper deck of *Vindictive*. Landed on the mole to recover casualties. Later, when he was proceeding with his party along the forward mess deck of *Vindictive*, a shell entered and burst close to him, killing one of his stretcher-bearers. He continued his work immediately, and by his personal example kept his stretcher-parties going.

The following are the statements of services of the medical officers promoted in connexion with the same operations, and recorded in THE LANCET of May 25th, 1918, p. 751 :—

Staff-Surg. JAMES MCCUTCHEON, R.N., *Vindictive* (promoted to Fleet-Surgeon).—Was the senior medical officer of the force. It would be difficult to exaggerate the splendid qualities displayed by this officer. He organised the medical arrangements excellently, and imbued his subordinates with a fine spirit, and by his own personal skill and attention contributed to the saving of the lives of many gallant officers and men.

Surg. HENRY ST. C. COLSON, R.N. (promoted to Staff-Surgeon).—Was attached to the R.M. storming party. Worked for many hours under the greatest disadvantages in gas fumes and by the light of a torch only with the utmost devotion to duty.

The names of the following medical officers are mentioned in a despatch from Vice-Admiral Sir Roger Keyes, K.C.B., C.M.G., C.V.O., D.S.O., commanding the Dover Patrol, for distinguished services in connexion with the same operations :—

Surg. S. W. Grimwade, R.N.; Surg. A. C. V. Green, R.N.; Surg. F. M. Payne, R.N.; Surg.-Prob. P. C. du Toit, R.N.V.R.; Surg.-Prob. G. F. Abercrombie, R.N.V.R.

The following awards to medical officers, all members of the R.A.M.C. unless otherwise stated, are announced. The dates in parentheses, in those cases where bars have been awarded, refer to the number of THE LANCET in which a record of the original decoration will be found. A further list of awards of the Military Cross will be published next week.

Bar to the Distinguished Service Order.

Capt. (acting Lieut.-Col.) FRANCIS CASEMENT, D.S.O.—For conspicuous gallantry and devotion to duty when he evacuated all the wounded and salved a large quantity of surgical material, blankets, and stretchers during a long retirement. His courage, coolness, and resource were most marked during the whole of this trying period. (June 9th, 1917, p. 894.)

Major (temp. Lieut.-Col.) HUGH ALLAN DAVIDSON, D.S.O.—For conspicuous gallantry and devotion to duty. When in command of his unit he maintained the advanced dressing station in spite of heavy shelling by the enemy, only withdrawing when ordered to do so. He visited the regimental aid-posts under heavy shelling, and by his example and energy many casualties were evacuated which might otherwise have been lost. (Jan. 6th, 1917, p. 37.)

Capt. (acting Lieut.-Col.) THOMAS SWAN EVES, D.S.O.—For conspicuous gallantry and devotion to duty. He was in charge of an advanced dressing station which was being heavily shelled by the enemy, and he personally and thoroughly carried out a complete change of organisation. Later he was superintending the loading of ambulance cars near a railway bridge which was a special target for the enemy's guns, and though twice thrown over and bruised by bursting shells he stuck to his post till all the wounded had been dressed and evacuated. His fine performance under continuous shell fire till the enemy were close upon him was a splendid example to all. (Jan. 12th, 1918, p. 78.)

Lieut.-Col. FITZGERALD GABBETT FITZGERALD, D.S.O.—For conspicuous gallantry and devotion to duty. When his casualty clearing station was heavily shelled he not only evacuated his patients to places of safety, but salved practically all the stores of his unit. This action was performed twice over, and on both occasions his courage and ability were pre-eminent. (Jan. 6th, 1917, p. 37.)

Major (Temp. Lieut.-Col.) HARRY BEATTY KELLY, D.S.O.—For conspicuous gallantry and devotion to duty. When the camp, in which over 40 stretcher cases were collected, was heavily shelled, he collected the bearers and removed the wounded to a position of safety. Again, when the infantry were being withdrawn, he collected casualties with the bearers and carried them through a heavy barrage to the ambulance cars, thus saving several lives and setting a fine example to his men. (Jan. 6th, 1917, p. 37.)

Lieut.-Col. JOHN POWELL, D.S.O.—For conspicuous gallantry and devotion to duty during a long period of active operations. Owing to the great number of extemporised formations from the divisions, which increased continually from day to day, the task of providing adequate medical facilities was one of extreme difficulty. By his indefatigable energy and powers of organisation he successfully met all demands, and completed the evacuation of all wounded with splendid efficiency. On one occasion, hearing some wounded had been left behind, he went himself, under heavy and continual shell and maching-gun fire, with three ambulances, and brought them in. Throughout his conduct was beyond all praise. (June 15th, 1918, p. 855.)

Temp. Capt. (acting Lieut.-Col.) LAWRENCE DREW SHAW, D.S.O.—For conspicuous gallantry and devotion to duty. He was placed in charge of the forward division of the combined field ambulances. Although constantly exposed to heavy shell and machine-gun fire he organised the system of evacuation and extended it to neighbouring divisional units. By his inspiring example and disregard of danger he ensured a complete and successful evacuation of the wounded. (June 9th, 1917, p. 893.)

Capt. (acting Lieut.-Col.) WILLIAM TYRRELL, D.S.O., M.C., Spec. Res.—For conspicuous gallantry and devotion to duty when in charge of a line of evacuation. He worked continuously for six days, and it was due to his gallantry, organisation, and energy that touch was maintained so efficiently with the brigades, and so many casualties evacuated. He displayed great courage and coolness throughout, and inspired those under him by his fine example. (Jan. 12th, 1918, p. 78.)

Distinguished Service Order.

Major ARCHIBALD JOHN COLLINS, M.C., Australian A.M.C.—For conspicuous gallantry and devotion to duty when in charge of the evacuation of wounded during intense fighting. Although the A.D.S. in which he was located was subjected to heavy enemy artillery fire, by his splendid energy, coolness, and courage he was enabled to evacuate safely several hundred casualties. His magnificent example inspired all who came in contact with him, and stimulated junior officers and exhausted stretcher-bearers to further efforts.

Temp. Capt. (acting Lieut.-Col.) KENNETH WILLIAM MACKENZIE, M.C. (late Capt. I.M.S.).—For conspicuous gallantry and devotion to duty when in charge of the forward evacuation, when he kept in touch with the retiring infantry, continually searching for and collecting the wounded. It was largely due to his great energy, skill, and foresight that so many of our casualties were so successfully evacuated.

Capt. (acting Lieut.-Col.) ARTHUR THOMAS PITTS, Spec. Res.—For conspicuous gallantry and devotion to duty. He established a dressing station in a forward and very exposed position. During two days and two nights he remained under continuous and terrific shell fire, dressing wounded and evacuating them. His courage and endurance under most trying conditions saved many valuable lives.

Capt. (acting Lieut.-Col.) LEOPOLD THOMAS POOLE, M.C.—For conspicuous gallantry and devotion to duty during a hostile attack. Hearing that a large number of wounded were uncollected, owing to normal communications having been cut by the attack, he proceeded at once to the area which was subjected to a sustained bombardment and organised stretcher parties, sending up all his available cars. It was owing to his fine courage and promptitude that upwards of 300 casualties were not left unattended.

Temp. Capt. FREDERICK NAYLOR STEWART, M.C.—For conspicuous gallantry and devotion to duty. He collected and dressed cases under the most intense shell fire, and on two occasions, by remaining behind after the order to withdraw had been given, succeeded in evacuating all the stretcher cases. He set a high example of courage and self-sacrifice. He was wounded in the face and thigh.

Temp. Capt. JAMES LENNOX STEWART, M.C.—For conspicuous gallantry and devotion to duty. Although his aid-post was in the open, a few yards behind the front line, he remained there, caring for the wounded, and through his efforts they were all dressed and evacuated. He was the only medical officer of the brigade left.

Capt. (acting Lieut.-Col.) CHARLES HERBERT STRINGER.—For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station. Owing to the whole force retiring, the collection and evacuation of large numbers of wounded, who were lying in thick woods, was a task of extreme difficulty in view of the rapid advance of the enemy. Although subjected to heavy fire, he remained behind till the enemy were almost up to his position, and by skilful organisation he succeeded in evacuating practically all the wounded. His magnificent courage and devotion saved many wounded from falling into the enemy's hands.

Capt. (acting Lieut.-Col.) JOSEPH HUGH WARD, M.C., Spec. Res.—For conspicuous gallantry and devotion to duty while in command of a cavalry field ambulance. During two days of intense fighting, in spite of the enforced moves of his unit, he continued to keep an A.D.S. open until the last possible moment to deal with large numbers of wounded, only retiring when all had been evacuated and when ordered to do so. Throughout this period he showed an example of pluck and determination beyond all praise.

Temp. Capt. ROGER LLEWELLYN WILLIAMS, M.C.—For conspicuous gallantry and devotion to duty during operations, when, with the C.O. and adjutant, he was the last to withdraw. Shortly after the C.O. was severely wounded, but, with the assistance of another officer, he carried him away for over half a mile under intense machine-gun and rifle fire at close range. Afterwards he continued to dress the wounded, including the adjutant, under the most intense fire, and throughout the withdrawal he showed the utmost energy and devotion to duty.

Temp. Capt. (acting Major) HERBERT GEORGE WILLIS, M.C.—For conspicuous gallantry and devotion to duty. When in command of a bearer division of the field ambulance throughout ten days' fighting he kept all in order by visiting the R.A.P.'s and ambulance relay posts, and when the trolley line was destroyed by shell fire he reorganised the system of evacuation, going round the posts and making the necessary arrangements at great personal risk. By his action he ensured the clearance of the wounded.

Second Bar to the Military Cross.

Temp. Capt. (acting Major) CHARLES BROMLEY DAVIES, M.C.—For conspicuous gallantry and devotion to duty while in charge of an advanced dressing station. His energy throughout whilst supervising the collection of the wounded was remarkable, and it was due to him that the collection and evacuation of the wounded was so quickly and thoroughly carried out. Though slightly wounded he remained at duty for another eight days, when he was severely wounded. His courage and energy were of a very high order. (M.C. Sept. 2nd, 1916, p. 450; bar, July 28th, 1917, p. 135.)

Temp. Capt. JAMES WALLACE MACFARLANE, M.C.—For conspicuous gallantry and devotion to duty in going under heavy shell fire to the assistance of a wounded man who was lying in the shelled area, dressing his wounds, and getting him safely to cover. He without doubt saved the man's life. (M.C. August 4th, 1917, p. 175; bar Feb. 9th, 1918, p. 234.)

Bar to the Military Cross.

Temp. Capt. PHILLIPPE BERNARD BELANGER, M.C.—For conspicuous gallantry and devotion to duty when the enemy had penetrated the defences on the left of his battalion in support and were outflanking battalion headquarters. He went across 300 yards of ground swept by severe machine-gun and rifle fire to assist a wounded officer, and had him carried into safety. He displayed great courage and self-sacrifice throughout operations. (Oct. 27th, 1917, p. 658.)

Capt. (acting Major) HENRY BRYAN FROST DIXON, M.C.—For conspicuous gallantry and devotion to duty. This officer remained behind in "No Man's Land" and dressed three officers under extremely heavy machine-gun fire, and helped to carry a wounded man more than two miles to a place of safety. Later he continued to dress all wounded, although practically surrounded by the enemy. His cheerfulness and disregard of personal danger under these exceptionally trying circumstances inspired all ranks. (Nov. 8th, 1916, p. 881.)

Capt. WALTER ELLIOT ELLIOT, M.C., Spec. Res.—For conspicuous gallantry and devotion to duty. He established a regimental aid-post and for 12 hours, assisted by two officers, and in spite of continuous shelling, attended to over 250 wounded and succeeded in evacuating all to the dressing station. It was due to his personal courage and example that this was successfully carried out. (June 23rd, 1917, p. 969.)

Capt. (temp. Major) JAMES DOUGLAS FIDDES, M.C.—For conspicuous gallantry and devotion to duty. In charge of an advanced field dressing station, which was heavily shelled, he successfully evacuated all the wounded to a safer place. He also went up to the front when the officer in charge there was exhausted and gassed, and superintended the evacuation of all the wounded. (Feb. 9th, 1918, p. 234.)

Temp. Capt. JAMES PHILLIPS JONES, M.C.—For conspicuous gallantry and devotion to duty. He was in charge of an advanced dressing station, and when the village had been temporarily evacuated he was entirely responsible for the getting away safely of many of the wounded. Throughout the ten days of the battle he displayed the most conspicuous ability, cool courage, and devotion to duty. (Feb. 9th, 1918, p. 234.)

Temp. Capt. RONALD SINCLAIRE KENNEDY, M.C.—For conspicuous gallantry and devotion to duty. When in charge of advanced bearers he collected and led forward reinforcing bearer squads in a most gallant manner through a heavy barrage and through lines of retiring infantry, until he gained touch with the regimental aid-post. He cleared many wounded who would otherwise have been left to the enemy. A splendid example of persevering gallantry and fearlessness. (Oct. 6th, 1917, p. 549.)

Temp. Capt. (acting Major) JOHN SAMUEL LEVIS, M.C.—For conspicuous gallantry and devotion to duty. When in charge of stretcher-bearers at the advanced dressing station, his courage and example in leading squads over heavily shelled ground were the means of saving many lives. When ordered to evacuate he displayed great ingenuity and resource in saving his personnel and equipment. Throughout the operations he has rendered most valuable services. (Feb. 3rd, 1917, p. 200).

Temp. Capt. JAMES MANUEL, M.C.—For conspicuous gallantry and devotion to duty, whilst battalion medical officer. During a withdrawal he frequently dropped back unaccompanied by medical staff and under very heavy fire attended to casualties. His conduct throughout the operations was of a high order. (Feb. 9th, 1918, p. 234.)

Temp. Capt. JOHN HAY MOIR, M.C.—For conspicuous gallantry and devotion to duty. During a withdrawal he repeatedly went out into the open, under heavy fire, to attend to the wounded. Throughout the withdrawal 7 officers of the battalion were wounded. That only one was left in the hands of the enemy was largely due to the magnificent courage which he displayed. (Nov. 18th, 1916, p. 881.)

Temp. Capt. GEORGE RANKINE, M.C.—For conspicuous gallantry and devotion to duty during a withdrawal. He superintended the evacuation of wounded without rest and at great personal risk, notably when the left flank became exposed, and he led the bearers with great courage near the railway embankment and evacuated all the wounded under heavy artillery and machine-gun fire. (Nov. 13th, 1915, p. 1111.)

Temp. Capt. CHARLES ROCHE, M.C.—For conspicuous gallantry and devotion to duty in evacuating wounded from the front line to the advanced dressing station. Four out of five collecting posts occupied by him were heavily shelled, but he continued to work incessantly, and evacuated a large number of wounded. (Nov. 4th, 1916, p. 806.)

Capt. THOMAS VICTOR SOMERVILLE, M.C.—For conspicuous gallantry and devotion to duty. When his battalion was about to withdraw and the wounded could not be brought to his aid-post in time, he went up to the firing line and stayed there attending to the wounded till all the troops had withdrawn. His gallant conduct saved many lives. (Jan. 22nd, 1916, p. 215.)

Capt. (acting Major) JOHN STEPHENSON, M.C., Spec. Res.—For conspicuous gallantry and devotion to duty in continuing to dress cases in the open under heavy shell fire. When the advanced dressing station was heavily gas-shelled and several casualties caused he saved many of the patients and staff from being gassed by his example and coolness. On one occasion he went through a heavy barrage to the regimental aid-post, and by his coolness and judgment all ranks were encouraged persevere in clearing the wounded. (Oct. 6th, 1917, p. 550.)

Temp. Capt. CHARLES GORDON TIMMS, M.C.—For conspicuous gallantry and devotion to duty during recent operations. He continued to collect and evacuate wounded from his post, though several times nearly surrounded by the enemy and under heavy shell fire. By his fine courage and self-sacrifice he was able to get away a large number of wounded under most difficult conditions. (July 28th, 1917, p. 135.)

Temp. Capt. JOHN WILFRED WATTHEWS, M.C.—For conspicuous gallantry and devotion to duty during the evacuation of a line. He displayed the utmost courage and coolness in evacuating wounded under very heavy shell fire, and it was entirely owing to his energy and personal example that the whole of the wounded were got away in safety. Later, having lost the whole of his medical outfit, he rendered invaluable assistance in rallying the men in his vicinity. (Dec. 1st, 1917, p. 838.)

FOREIGN DECORATION.

Belgian.

Ordre de la Couronne: Chevalier.—Temp. Capt. A. Stokes, D.S.O., R.A.M.C.

RECOGNITION OF WAR SERVICE.

A correspondent writes to us as follows:—

"Why is it that medical men who have been serving at home ever since the war started have no badge or mark to indicate how long their period of service has lasted? Those serving abroad have their Mons star and ribbon, or their chevrons, according to their length of service, although they may have been no closer to the enemy guns than we are here in London. And it is admitted that, although the medical men abroad have periods of continuous and severe work, they also have periods of comparative slackness, while the men at home have one constant flow of work all the time. The V.A.D.'s and the special constables have been given distinguishing marks to show their time of service, but no one seems to have given a thought to the doctor. The heads of the Army Medical Service, as Regulars, can hardly have intimate knowledge of the wants of the Territorial or temporary members of the Service. But it is not unfair to ask, What would have happened if we had had to rely entirely on the Regular members of the R.A.M.C. for the treatment of all of our wounded? And are not these men who have been doing good work in the auxiliary services entitled to recognition? Should they not at any rate receive some distinguishing badge to show the length of their service? It is unjust for men who have served right from the start to be classed with those who were virtually conscripted."

We agree with our correspondent in seeing no reason why those who have borne the burden at home should not have some mark of recognition.

THE CALL FOR EMERGENCY SUBSTITUTES.—The Central Medical War Committee has from time to time appeals made to it for temporary assistance in practices in which, owing to illness or death of a partner, the incumbent is not only unable to do the work, but is unable to secure adequate assistance from his colleagues. It is found impossible often to secure a locum tenent through the ordinary channels. Offers of assistance for two, three, or four weeks from practitioners, either men or women, who could be free at short notice would be greatly valued, and should be sent at once to the secretaries of the Central Medical War Committee, 429, Strand, W.C. 2.

Obituary.

FREDERICK EUSTACE BATTEN, M.D. CAMB., F.R.C.P.,

OUT-PATIENT PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; AND HONORARY PHYSICIAN TO THE KING GEORGE HOSPITAL.

Dr. Frederick Eustace Batten, who died two days after a severe operation on Saturday, July 27th, was a son of the late John Winterbotham Batten, K.C., and brother of Dr. Rayner D. Batten. He was educated at Westminster and Trinity College, Cambridge, and at St. Bartholomew's Hospital, where he was house physician to Sir William Church and casualty physician. He also spent a short time doing post-graduate work in Berlin, where he acquired an intimate knowledge of the German language. His medical qualification dates from 1891 when he took the Bachelorship of Medicine at Cambridge, followed by the M.D. degree in 1895. In 1894 he became a Member of the Royal College of Physicians of London, and seven years later was elected to the Fellowship of that body.

The whole of Batten's professional career was intimately associated with two adjacent institutions—the Hospital for Sick Children, Great Ormond-street, where he held in succession the posts of medical registrar, assistant physician, and physician, and the National Hospital for the Paralysed in Queen-square, where he was elected pathologist in 1899 and a member of the honorary staff in 1900. For more than 20 years he gave unlimited time and the greater part of his energies to the care and cure of his hospital patients in the quiet backwater of Bloomsbury, which has become an important medical centre. There it was that he continued to pursue pathological researches long after he had ceased to hold any official position in the laboratories, and there he built up his reputation not only as a scientific neurologist, but as a physician and teacher who inspired complete confidence in his patients, and who earned and held to the last the affection and respect of colleagues and students. "Great Ormond-street" and "The National" have lost one of their truest friends, one of their most loyal servants, one who never failed, was never late, and never shirked the call of duty, however great the sacrifice. In spite of a large consulting practice he was always ready to undertake the more thankless tasks connected with hospital or school administration. At the time of his death he was dean of the medical school and secretary of the medical committee at the National Hospital, and we have no hesitation in saying that his conscientious thoroughness and zeal in these positions have created a precedent which his successor will find difficulty in following. He was a constant attendant at scientific meetings, and he will long be remembered for his services to the Medical Officers of Schools' Association, of which he was honorary secretary and president, and to the Neurological, Ophthalmological, and Clinical Sections of the Royal Society of Medicine. He was a consulting physician in the highest and most exact sense; his patients invariably reached him through the medium of his fellow practitioners.

Batten made many contributions to medical literature, mostly neurological, generally short, always to the point, and invariably characterised by the accuracy of his observations and the critical acumen of his interpretation. His chief interest was undoubtedly centred on the pathological and clinical pictures of organic disease, and it would hardly be inaccurate to say that he faced psychological problems, and especially their modern aspects, with some diffidence and reluctance. If this was true of his attitude to the problem it was otherwise to the patient, who never failed to gain help in abundance from his fund of human sympathy and understanding. Perhaps his pet subject was that of acute poliomyelitis, and his Lumleian Lectures delivered at the Royal College of Physicians in 1916 constitute the most exhaustive monograph on that disease which has appeared in this country. The text-book on Diseases of Children which he edited with Sir A. E. Garrod and Dr. J. H. Thursfield, and to which he contributed two important chapters, was published in 1913, and many of his papers are to be found in *Brain* and THE LANCET.

But Batten's first claim to the memory of those who knew and loved him—and they are many—lay in his character. His simplicity, his directness of thought and word, his love of children and the children's devotion to him, his geniality and tolerance, endeared him to all who had the privilege of his friendship. With strong domestic instincts, he was at his best as a host in his own house, full of boyish interest in every subject, always keen to acquire knowledge and ever diffident to claim it. No one could spend an hour or two in his company and fail to draw some inspiration from the atmosphere of honesty, modesty, and kindliness which seemed to be his natural environment. Death came at the early age of 52, and swept away without warning a man still in his prime and full of life and of that energy which he had always given without stint to the furtherance of science and in the service of his fellows. He married in 1907 Jean, the daughter of the late John James Stevenson, F.R.I.B.A., who survives him, and to whom a host of friends extend their deepest sympathy.

A friend and colleague writes:

The death of Dr. F. E. Batten has caused a gap in the ranks of neurologists which will not readily be filled. Yet work such as his will always live, for it was characterised throughout by perfect accuracy and width of range of observation, profound learning, extensive research, and all the instinct of the trained investigator. His name will probably be chiefly associated with nervous diseases in children, and especially with the study of encephalitis and myelitis, the etiology, pathology, and treatment of which formed the subject of his Lumleian Lectures for 1916. In these lectures he abandoned his earlier theories as to the vascular or mechanical origin of poliomyelitis, and accepted the more modern view of its inflammatory and infective nature. But his essentially practical aim was, perhaps, most exemplified in the ingenuity which he displayed in designing and fashioning celluloid splints adapted for the treatment of every variety of infantile paralysis. In his wards at Great Ormond-street Hospital and elsewhere he was always ready to demonstrate and popularise the use of this form of apparatus and to show its value in preventing deformities, whilst enabling paralysed children to be up and about instead of lying helplessly in bed or painfully dragging heavy iron instruments attached to their withered limbs. Amongst his numerous contributions to neurological literature may be mentioned his admirable introduction to a discussion on the myopathies at the International Medical Congress in 1913. In this connexion he established the identity of myatonia congenita with congenital myopathy. Of many brilliant papers published in *Brain*, two at least may be regarded as classics—that on "Muscle Spindles" (1897–98), a reprint of which appears as an appendix to Gowers's "Diseases of the Nervous System," and another on "The Position of the Head in Cerebellar Diseases" (1903).

Batten's personality was attractive to all who knew him. To all he was genial, cheerful, and unaffectedly kind in manner, and he was ever ready to help and inspire his juniors with some of his own enthusiasm for work. Although naturally modest and retiring, he was fully capable of holding his own in public controversy, and his adversaries in discussion always found him a tough though scrupulously fair and courteous antagonist. To his intimate friends he revealed a strength of character, and depth of conviction, an uncompromising conscientiousness, and a code of morals almost puritanic, yet combined with kindliest toleration and sympathy with his fellow-men.

ROBERT OLIVER CUNNINGHAM, M.D. EDIN., F.L.S.,

EMERITUS PROFESSOR OF BOTANY AND ZOOLOGY, QUEEN'S COLLEGE, BELFAST.

WE regret to announce the death of Professor R. O. Cunningham, which took place at his home in Paignton on Sunday, July 14th. Professor Cunningham, who retired from his University chair about 16 years ago, had been in indifferent health for some time past, and before and immediately after his retirement he underwent severe operations for volvulus.

A son of the manse, his father, the late Rev. W. B. Cunningham, was Free Church minister at Prestonpans, N.B., for many years, and came out at the disruption in 1843, a fact of which his son was very proud. Robert Oliver Cunningham, who was 77 years of age at the time of his death, graduated in 1864 at Edinburgh University, writing his thesis on the Solan Goose. A fellow student and friend of the present Lord Chancellor, his tastes, like the latter's, did not turn to medicine or medical practice, and he from the start devoted himself to the study of natural history. Early in his career he was given an appointment as assistant surgeon in the Royal Navy, and went on an exploratory trip in H.M.S. *Nassau*,

an old 800-ton auxiliary steam brig. He spent nearly three years in the Straits of Magellan and the regions thereabout while the straits were being charted and sounded, and acquired a rich store of specimens, which were skinned, dried, and bottled in spirit within the narrow confines of the cabin allotted to an assistant surgeon.

Soon after coming home he was lecturer at the Agricultural College, Cirencester, and after holding this post for a short period he was appointed to a professorship at Queen's College, Belfast, in succession to Sir Wyville Thompson, who resigned on being appointed to the *Challenger* expedition. This office he held for upwards of 30 years and carried out the duties with immense zeal, and with acceptance to a great number of students. In 1882 the Royal University of Ireland, of which he was a Fellow, conferred on him the honorary degree of D.Sc. He was never very robust, and the heavy work entailed by the joint offices of professor not only in zoology and botany but also geology—with practical classes in the first two subjects—was a great strain on his physical powers. The long vacation was always welcome, and indeed formed a necessary opportunity for recruiting for the winter session.

Cunningham was not what is commonly termed a "popular" type of man. Indeed, for those who sought popularity he had something approaching contempt. He lived to a very high standard, was most absolutely sincere and straightforward, and for those of similar character among students or colleagues he readily acquired a regard which was reciprocated and often deepened into friendship. He would pick this or that man out of his class and note him down as "a very good fellow" or "a very able fellow," or both, but was equally quick to discern the shirker, whom he would designate as "very unsatisfactory." Many old students kept in touch with him years after they had gone out into the struggle of life to the colonies or elsewhere, and nothing gave him greater pleasure than to meet or hear from such an one. He had a profound and indeed encyclopædic knowledge of his subject, and taught his pupils to observe; but he rather erred in his lectures by trying to get too much in the time which was available, and in university extension lectures similarly would race away ahead of his audience and above their heads. He was one of the most outstanding men on the staff in his time and for many years sat on the College council.

Himself a staunch Presbyterian and deeply religious, though seldom speaking about religion, he was broad minded and was at all times critical of religious intolerance. He did not hesitate to criticise Orangemen or Romanists alike for this failing. One of his best friends for many years was a French Jesuit colleague at the Royal University, but he was not an admirer of the Catholic priest in Ireland, generally speaking.

Apart from his Notes as naturalist in the *Nassau*, it is to be regretted that so little is left as a contribution to literature by one whose knowledge, especially of the geographical distribution of plants, was so exhaustive, but he did not seem ever to contemplate writing a text-book with favour, and was singularly devoid of a desire to turn his abilities to such occupation as would materially benefit him in a monetary way. He was a scientist pure and simple, and would for choice have devoted himself purely to botanical work. He was predeceased by his two brothers, both of whom were in the medical profession (one of them, Dr. David D. Cunningham, well known in the I.M.S.), but is survived by a widow.

THE SERVICES.

ARMY MEDICAL SERVICE.

Major-Gen. (temp. Lieut.-Gen.) C. H. Burtchaell, C.B., C.M.G., is appointed an Honorary Surgeon to the King.

Temp. Col. Sir T. C. English, K.C.M.G. (Captain, R.A.M.C., T.F.), relinquishes his temporary commission on reposting, and is granted the honorary rank of Colonel.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. E. B. Knox relinquishes the temporary rank of Colonel on reposting.

Lieutenant-Colonels to be acting Colonels whilst employed as Assistant Directors of Medical Services of Divisions: A. M. MacLaughlin, FitzGerald G. FitzGerald, and W. R. Blackwell (whilst employed as Assistant Director-General of Medical Services, British Armies in France).

Majors relinquishing the acting rank of Lieutenant-Colonel on reposting: H. B. Kelly, C. W. O'Brien, R. F. M. Fawcett.

To be acting Lieutenant-Colonels whilst in command of a Medical Unit: Capt. (acting Major) M. O. Wilson and Majors J. M. H. Conway and G. A. K. H. Reed.

Officers relinquishing the acting rank of Major on reposting: Capt. F. G. A. Smyth; Temp. Capts. S. J. L. Lindeman, C. G. Sutherland, E. R. D. Maconochie, R. M. Handfield-Jones, H. Upcott, E. Biddle.

The undermentioned Captains to be Majors: (Acting Lieut.-Cols.) G. H. Stevenson, W. H. Forsyth, E. B. Lathbury, C. Scaife, E. D. Caddell, W. E. Lunn, F. L. Bradish, W. J. E. Bell, C. W. Bowle, W. J. Thompson, E. C. Phelan, J. J. O'Keeffe, E. J. Kavanagh, O. C. P. Cooke; (Bt. Majors) D. M. Corbett, (acting Lieut.-Col.) B. Johnson, R. W. D. Leslie, J. A. Bennett; (Acting Majors) T. W. Browne, C. H. Denyer; (Temp. Major) D. T. MacCarthy, A. C. Amy, A. H. Heslop, W. Mitchell, E. J. Elliot, E. Gibbon, J. R. Foster, A. M. Benett, G. P. A. Bracken, H. L. Howell, W. F. N. Loughnan, A. H. Jacob.

To be acting Majors: Capts. A. C. Jebb, C. Kelly, C. C. Jones, A. R. Wright, T. D. Inch, J. J. H. Beckton, T. L. Fraser; Temp. Capts. W. W. Wells, C. M. Kennedy, C. McM. Wilson, R. L. Scott, G. Richardson, W. H. W. Attlee, A. J. Blake, H. B. Walker, F. R. Brown, R. V. Dolbey, W. J. Pearson, R. H. Lucas, J. S. Joly, A. E. Rayner, L. Leslie, H. V. Leigh, H. J. Milligan, M. Donaldson; Temp. Lieut. P. Murphy.

Temporary Majors, Canadian A.M.C., to be acting Lieutenant-Colonels while specially employed: S. R. Harrison, D. A. L. Graham.

Temporary Captains, Canadian A.M.C., to be acting Majors while specially employed: A. B. Schinbein, J. E. Campbell.

Capt. R. A. Peters is seconded for service under Ministry of Munitions.

Temporary Lieutenants to be temporary Captains: F. Penny, N. B. Walker, O. Marshall, H. McKenzie, D. MacKinnon, A. P. Nicolle, C. E. A. Goddard, B. V. Ward, J. H. Clatworthy, H. C. Malleson, W. M. McDonald, J. Jenkins, J. A. Valentine, H. Daw, J. W. Trevan, J. H. Trench, W. B. Blandy, R. Jamison, T. E. Banister, A. B. Robertson, G. W. Stephens, G. W. Pope, G. C. F. Roe, J. P. Brennan, C. G. G. Winter, D. McGregor, J. R. Watson, C. Bernard, W. E. Procunier, R. R. H. Wonnacott, H. H. Stiff, C. Visger, J. B. Fearn, C. W. Freeman, R. R. Wade, H. C. Martin, E. D'A. McCrea.

To be temporary honorary Captains: Temp. Hon. Lieut. J. F. Cooper; J. Brereton-Barry, late temporary Captain, whilst employed at the Welsh Hospital, Netley.

W. R. D. Daglish, late temporary Lieutenant, is granted the honorary rank of Lieutenant.

Officers relinquishing their commissions: Temp. Major J. W. Struthers; Temp. Capts. J. D. W. Beavis, M. Cohen, F. B. Gurd, R. C. Muir, W. Sowerby, W. Enraght, P. J. Lydon, G. Fehrsen, O. E. S. Wishart, A. H. B. Pearce, L. M. Rosten, W. Harvey, S. R. Hunter, J. R. M. MacKenzie, T. M. Thomson, T. Sheehan, W. J. P. Lillis, L. D. I. Graham, P. A. Dykes, H. F. Holmden; Temp. Hon. Capt. A. T. Paterson; Temp. Lieuts. S. J. Kerfoot, G. Birch, R. E. V. Hale, W. Taylor, R. Larkin, C. J. Nellan, R. G. Williams, W. J. Lord, W. Chapman, F. G. Power, H. M. Thompson, J. K. Milligan, R. A. McCrea, A. R. Soady, H. A. Evans, B. S. Johnson, W. S. Alderson, H. W. Elwell.

SPECIAL RESERVE OF OFFICERS.

Capt. (acting Major) W. Barclay to be acting Lieutenant-Colonel whilst in command of a Medical Unit.

Capt. P. J. Gaffikin relinquishes the acting rank of Major on reposting.

Captains to be acting Majors: W. W. Wagstaffe, J. W. Gray, G. G. Alderson.

TERRITORIAL FORCE.

Lieut.-Cols. J. Clay and P. C. Burgess to be Assistant Directors of Medical Services and to be temporary Colonels whilst so employed.

Major E. C. Clements is seconded.

Major (temp. Lt.-Col.) M. Dunning relinquishes his temporary rank on ceasing to command a Field Ambulance.

Majors T. A. Barron and J. O. Summerhayes to be acting Lieutenant-Colonels whilst commanding a Field Ambulance.

The undermentioned Captains to be acting Majors whilst specially employed: G. Stevenson, T. C. Clarke, J. M. White (and remain seconded), H. Paterson, R. E. T. Tatlow.

Major H. C. Donald and Capt. H. N. Barnett to be acting Lieutenant-Colonels whilst specially employed.

Capt. (temp. Major) A. A. Martin to be Major.

The undermentioned Captains (acting Majors) relinquish their acting rank on ceasing to be specially employed: J. M. Plews, F. Wigglesworth, A. C. Alport, F. Ward.

Captains to be acting Majors whilst specially employed: T. B. McKee, A. E. Ironside, G. L. Chiene (and to remain seconded), H. Burrows (and to remain seconded), H. C. C. Hackney, F. Clayton, P. C. P. Ingram, A. C. Alport.

Capt. (temp. Major) J. Hamilton relinquishes his temporary rank on ceasing to be specially employed.

Capt. H. H. Rayner is restored to the establishment.

Capt. J. M. Milne to be a Deputy Assistant Director of Medical Services and to be acting Major whilst so employed.

Capt. (acting Major) A. Ramsbottom relinquishes his acting rank on vacating an appointment as Deputy Assistant Director of Medical Services and is restored to the establishment.

Lieuts. R. T. Pearl and J. Waterston to be Captains.

Cpl. (acting Staff-Sergt.) H. H. Clay to be Lieutenant.

ROYAL AIR FORCE: *Medical Branch.*

Lieut. Drury Pennington to be Captain.

T. H. James, A. A. Wilkinson, R. E. V. Hale, are granted temporary commissions as Captains.

C. M. John, K. Batten, G. Hughes, H. T. Rymer, J. Valerie, J. P. Wells, J. P. Hosford, C. Duggan, A. St. J. Hennessy, E. H. L. Le Clezio, O. S. Martin, O. P. Turner, are granted temporary commissions as Lieutenants.

DONATIONS.—The honorary treasurer of the Queen's Hospital, Frognal, Sidcup, Kent, has received through the King, a donation of £1000 from General and Mrs. Holdsworth, of Staveley Court, Eastbourne, towards the funds of the institution, and the Queen of the Belgians, through Queen Mary, has sent £100. The Queen of the Belgians has also sent £100 to the Queen Mary's Convalescent Auxiliary Hospitals, Roehampton.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia was held on July 25th, Dr. Norman Moore, the President, being in the chair. The following were admitted Members of the College:—

Geoffrey Bourne, L.R.C.P.; Francis Henry Mosse, L.R.C.P.; Ffrangcon Roberts, M.D. Camb., L.R.C.P.; William Willis Dalziel Thomson, M.D. Belfast; John Gratton Wilson, M.B. Lond., L.R.C.P.; Cecil Denyar Wood, M.B. Oxf.

—Licences to practise physic were granted to 73 candidates. The Diploma in Public Health was granted in conjunction with the Royal College of Surgeons to six candidates.—On the nomination of the President and Council, censors, examiners, and other College officers were elected as follows:—

Censors.—Dr. G. Newton Pitt, Dr. F. W. Mott, Sir Humphry D. Rolleston, K.C.B., Dr. Raymond H. P. Crawfurd.
Treasurer.—Sir Dyce Duckworth.
Emeritus Registrar.—Dr. Edward Liveing.
Registrar.—Dr. J. A. Ormerod.
Harveian Librarian.—Dr. T. H. Arnold Chaplin.
Members of the Library Committee.—Dr. Hector W. G. Mackenzie, Dr. A. F. Voelcker, Dr. H. Ritchie Spencer, Dr. Cyril Ogle.
Curators of the Museum.—Dr. J. Mitchell Bruce, Sir Seymour J. Sharkey, Dr. F. W. Andrewes, Dr. William Hunter, C.B.
Finance Committee.—Dr. Sidney P. Phillips, Dr. A. T. Davies, Dr. H. R. Spencer.
Examiners.—Chemistry: Mr. W. H. Hurtley. Physics: Mr. A. W. Porter, Mr. J. H. Brinkworth. Practical Pharmacy: Dr. R. A. Young, Dr. David Forsyth, Dr. W. M. Stevens, Dr. J. A. Gunn, Dr. E. Mellanby. Physiology: Dr. D. H. de Souza, Mr. J. S. Macdonald, F.R.S. Anatomy: Dr. E. Barclay-Smith. Medical Anatomy and Principles and Practice of Medicine: Dr. A. G. Barrs, Dr. F. J. Wethered, Dr. J. Calvert, Dr. William Hunter, Dr. H. G. Turney, Dr. J. Fawcett, Dr. J. S. Collier, Dr. Robert Hutchison, Dr. F. J. Poynton, Sir John F. H. Broadbent. Midwifery and Diseases peculiar to Women: Dr. G. F. Blacker, Dr. H. R. Andrews, Dr. T. G. Stevens, Dr. Hugh J. M. Playfair, Dr. W. F. Victor Bonney.
Public Health.—Part I.: Mr. J. H. Ryffel. Part II.: Dr. E. W. Hope.

Dr. L. G. Guthrie and Dr. P. Horton-Smith-Hartley were elected councillors in place of Dr. R. H. P. Crawfurd and the late Dr. Michell Clarke.

—Communications were received from the Secretary of the Royal College of Surgeons reporting proceedings of the Council of the College on May 9th, June 13th, and July 11th respectively; Mrs. Valentine Fleming, asking permission to have a copy made of the portrait of her grandfather, the late Sir Richard Quain (this was granted); the Minister of National Service, thanking the College for providing accommodation for the medical examination of doctors in the London district; and Sir George Kenyon, K.C.B., Director of the British Museum, returning thanks for a gift from the College to the Museum.—A copy of the revised edition of the "Nomenclature of Diseases," 1918, was received, in connexion with which it was resolved:—

1. That the thanks of the College be presented to Dr. Leonard Guthrie for his work as secretary of the Committee, and as editor of the Nomenclature, and that he be asked to accept an honorarium of 200 guineas.
2. That the Registrar do send to each of the extra-Collegiate Members of the Subcommittee engaged on the work the thanks of the College for their valuable aid.

—On the recommendation of the Council the Moxon medal was awarded to Dr. F. W. Mott, F.R.S.—A report was received from the adjudicators of the Weber-Parkes prize, and it was resolved that no award should be made this year.—Dr. T. D. Acland was reappointed a representative of the College on the Court of Governors of the University of Sheffield.—A report from the representative of the College on the General Medical Council upon the proceedings of the Council in the session held in May last was received and entered on the minutes.—The Registrar proposed temporary by-laws to the effect that Dr. S. W. Curl and Dr. H. B. Day, being resident abroad, should be admitted to the Fellowship *in absentiâ*, any by-law to the contrary notwithstanding.—Dr. Sidney Martin and Sir Arthur Newsholme were re-elected members of the Executive Committee of the Imperial Cancer Research Fund.—The following recommendations from the Committee of Management were received and adopted:—

That the Leeds Grammar School be added to the list of schools recognised for instruction in chemistry and physics.

That the following Universities and Medical Colleges be added to the list of institutions whose graduates in medicine are admissible to the Final Examination of the Examining Board in England, under the conditions of Para. IV., Sect. III., of the Regulations—viz.: University of Vermont, Burlington; University of Alabama, Mobile, Ala.; Women's Medical College of Pennsylvania; Union University, Albany, N.Y.; University of Louisville, Ky.; St. Louis University School of Medicine, St. Louis; Long Island College Hospital, Brooklyn, N.Y.; University of Pittsburgh; and Medical College of State of South Carolina.

That King's College for Women be added to the list of schools recognised by the Board for instruction in chemistry, physics, and biology.

That the following schools be added to the list of schools recognised by the Board for instruction in chemistry and physics—namely, Downside College, Stratton-on-the-Fosse; Royal Masonic School, Bushey; Shrewsbury School, Shrewsbury; and Merchant Taylors' School, Crosby, Lancs.

That Barry Intermediate Schools, which are already recognised for instruction in chemistry and physics, be also recognised for instruction in biology.

That Syracuse University, New York, be added to the list of institutions whose graduates in medicine are admissible to the Final Examination of the Examining Board in England under the conditions of Para. IV., Sec. III., of the Regulations.

—Books and other publications presented to the Library during the past quarter were received, and the thanks of the College given to the donors. After some formal business the President declared the Comitia closed.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians and of the Council of the Royal College of Surgeons on July 25th, diplomas of L.R.C.P., M.R.C.S., were respectively conferred upon the undermentioned candidates (including 10 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Examining Board, and have complied with the by-laws:—

Abraham Abelson, B.Sc. Lond., Univ. Coll. Hosp.; James Franklin Adams, M.B. Tor., Toronto Univ.; Kaiku Ardeshir Anklesaria, Bombay Univ. and London Hosp.; Bernard Francis William Armitage, M.A. Camb., Cambridge Univ. and St. Bart.'s; Chas. Howard Backus, St. Mary's; Annie Hardy Banks, Royal Free and St. Mary's; *Frederick Grant Banting, M.B. Tor., Toronto Univ.; Gilbert Blurton, Birmingham Univ.; Martin Vincent Boucaud, St. Bart.'s; Maurice Charles Breese, Westminster; John Dutton Byrd, Manchester Univ. and St. Bart.'s; Francis Cavers, D.Sc. Lond., Univ. Coll. Hosp.; Edwin Alfred Clegg, Middlesex; Alfred Wilkinson Cocking, Guy's; Kathleen Mary Cogan, Royal Free and St. Mary's; Thomas Colley, Manchester Univ.; Norman Carwardine Cooper, Bristol Univ.; Cyril Charles Herbert Cuff, M.B., B.S. Durh., Durham Univ.; Pares Chandra Datta, M.B., Ch.B. Edin., Edinburgh Univ. and Middlesex; Evan Sherrah Davies, Westminster; Sidney Richard Eccles Davies, Cambridge Univ. and St. Bart.'s; Thomas Morris Davies, St. Mary's; Frank Swinburne Drewe, Oxford Univ. and St. Thomas's; Charles Bertram Dyson, Cambridge Univ. and Univ. Coll. Hosp.; Albert Eidinow, London Hosp.; Saad El Din Ahmed El Daab, St. Bart.'s; Frederick Knowles Escritt, Guy's; Lucie Gainsford, Madras and Charing Cross; Shanazar Galstaun Galstaun, Cambridge Univ. and St. Bart.'s; Edwin Stowell Gawne, Liverpool Univ.; Chapple Gill-Carey, Guy's; Stuart Victor Goldhurst, Cambridge Univ. and London Hosp.; Lawrence Handy, St. Bart.'s; Frank Tandy Harrington, Guy's; Geoffrey Gordon Havers, Cambridge Univ. and St. Bart.'s; Walter Anley Hawes, Guy's; Sydney Nuttall Hayes, Middlesex; Walter Ernest Heath, Cambridge Univ. and St. Bart.'s; Walter Sebastian Herman, Cambridge Univ. and London Hosp.; Thomas Cornelius Higgins, St. Bart.'s; Cyril Patrick Hines, St. George's; Jack Joffe, B.Sc., Guy's; Alfred Kenneth Ince Jones, L.D.S.Eng., Middlesex; *Edward Ek Dun Lau, M.B., B.S. Durh., Durham Univ.; Alexander Smirle Lawson, M.B. Tor., Toronto Univ.; Neville Hall Little, M.B. Tor., Toronto Univ.; Allan Wyndham Lloyd-Davies, Birmingham Univ.; Geoffrey Burman Lowe, Cambridge and Birmingham Univs.; Edith Mary Ponsonby Morris, St. Mary's; Kenneth Mullen, Guy's; Robert Alan Olphert, Cambridge Univ. and St. George's; *Irene Grace Parsons, Royal Free; Rowland John Perkins, St. Bart.'s; Gordon Frank Peters, Guy's; Mary Millicent Prior, Royal Free and St. Mary's; Percival George Quinton, Univ. Coll. Hosp.; Constance Amy Randall, Royal Free; Clifford George Jackson Rayne, St. Bart.'s; Frances Elinor Rendel, Royal Free and St. Mary's; Norman Rumboll, Cambridge Univ. and St. Bart.'s; John Andrew Adamson Prinski Scott, London Hosp.; Adolphe Gladstone Millott Severn, Guy's; William Henry Simmons, Guy's; Bertram Leslie Slater, London Hosp.; Victor Alexander Trevor Spong, St. Bart.'s; George Seymour Swan, Liverpool Univ.; Arthur Denis Symons, Bristol Univ.; Matthew Sydney Thomson, Cambridge Univ. and King's College Hosp.; Agnes Elizabeth Towers, Cambridge and Birmingham Univ.; Elsie Maud Visick, Royal Free; Yik Shing Wan, University College Hosp.; John Whittingdale, Cambridge Univ. and St. Bart.'s; and Vyvian Deane Wyborn, Charing Cross.

* Diploma of M.R.C.S. conferred on July 11th, 1918.

Diplomas in Public Health were conferred upon the following six candidates:—

Stephen Leonard Baker, L.R.C.P., M.R.C.S., Haslar and London Hosp.; Thomas Frederick Brown, L.R.C.P., M.R.C.S., Guy's; Gnanayudam Mangalanathan Dominick, L.R.C.P., M.R.C.S., University College Hosp.; Hyman Isaac, M.B., B.S. Lond., Guy's; Edmund Douglas Richardson, L.R.C.P., M.R.C.S., University College; and Edmund Leigh White, M.D., Ch.B. Edin., Edinburgh Univ. and University College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on July 16th the following gentlemen, having passed the requisite examinations, were admitted Fellows:—

Claude Hamilton Blair Avarne, M.R.C.S. Eng., L.R.C.P. Lond.; Francis Brown Craig, M.B., Ch.M. Sydney, Captain, Australian A.M.C.; William Robert Higgins, M.R.C.S. Eng., L.R.C.P. Lond., M.B., B.C., M.D. Camb., Captain, R.A.M.C.(T.); Edward Wilfrid Kirk, M.B., Ch.B. Edin., Captain, R.A.M.C.; David Lees, M.B., Ch.B. Edin.; Leonard Newsom Morris, M.R.C.S. Eng., L.R.C.P. Lond., M.B., Ch.B. Bristol, Lieutenant, R.A.M.C.(T.); Frederick Lionel Spalding, M.R.C.S. Eng., L.R.C.P. Lond.; Kenneth Vincent Trubshaw, M.R.C.S. Eng., L.R.C.P. Lond., M.B., B.S. Lond.; and Alexander Stewart Wilson, M.B., Ch.B. Glasg., Captain, South African M.C.

QUEEN'S UNIVERSITY OF BELFAST.—At the summer graduation ceremony, held on July 10th, the following degrees and diploma were conferred:—

M.D.—George J. Jones.

M.B., B.Ch., B.A.O.—First-class honours: William J. Lytle and Charles A. Whitfield. Second-class honours: Gladys E. Chambers, Samuel E. Duff, and Henry F. Macauley. Pass: Herbert Abernethy, Samuel Acheson, David D. Anderson, Annie E. E. Beattie, Frederick C. L. Bradbury, Samuel F. Breakey, Frederick Campbell, Thomas I. Candy, Gerard J. Crawford, David Cromie, Stewart Fullerton, John Grimson, Robin Hall, Mary E. Irwin, Amy C. McCallum, Hugh H. McClelland, John McGarvey, Daniel McLister, Edward A. Maguire, John A. Martin, William Michael, Thomas Montgomery, Hugh Paul, Charlotte Pedlow, John E. Rea, David A. E. Scott, Thomas Wallace, Percival S. Walker, and Andrew Watson.

Diploma in Public Health.—Robert Marshall, David R. Taylor, Denis K. Watterson, and Samuel Wright.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The seventy-seventh annual meeting of this association was held at Edinburgh on July 23rd and 24th, under the presidency of Lieutenant-Colonel John Keay, R.A.M.C. After the transaction of the usual business the President delivered his inaugural address. This was followed by papers on "The Prevention and Treatment of Neurasthenia and Other Functional Nervous Breakdowns," by Dr. Claud F. Fothergill, and "The Infective Factors in Some Types of Neurasthenia," by Dr. W. Ford Robertson. On the second day the members and their friends were hospitably entertained by Lieutenant-Colonel Keay and Mrs. Keay to luncheon and an At Home at the Edinburgh War Hospital, Bangour. The wards of this excellently equipped hospital were visited and demonstrations were given by Lieutenant-Colonel C. W. Cathcart, R.A.M.C. (T.) and Major Rankine on the Construction and Fitting of Provisional Artificial Limbs; by Lieutenant-Colonel Sir Harold J. Stiles, R.A.M.C., on interesting cases from the Orthopædic Department; and by Captain Edwin Bramwell, R.A.M.C., on cases illustrating Functional Neuroses. Major D. G. Marshall, I.M.S., and Dr. L. K. Davies showed Microscopic Preparations illustrating Malaria and Dysentery. By the kindness of the chairman and managers and Dr. G. M. Robertson, an At Home was held at the Royal Edinburgh Mental Hospital, Morningside. Owing to the war the annual dinner was not held, but the well-known hospitality of the Edinburgh members contributed in no small measure to the success of a very enjoyable and instructive meeting.

MIDWIVES (IRELAND) ACT, 1918.—At the recent election held pursuant to the provisions of the Midwives (Ireland) Act, 1918, the following four registered medical practitioners were elected by the registered medical practitioners resident in Ireland to act on the Central Midwives Board for Ireland (Section 3 (1) (b)): Sir Andrew J. Horne (Dublin); Sir William J. Smyly (Dublin); Sir John William Byers (Belfast); and Professor Henry Corby (Cork). The other seven members will be appointed by the Local Government Board for Ireland in due course.

URBAN VITAL STATISTICS.

(Week ended July 27th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 13·1, against 21·1 and 18·0 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 11·8, or 3·4 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 4·2 in Ilford, 5·6 in Wallasey, and 5·9 in Gillingham, to 22·1 in Blackburn, 24·3 in Warrington, and 26·1 in Walsall. The principal epidemic diseases caused 241 deaths, which corresponded to an annual rate of 0·8 per 1000, and included 71 from whooping-cough, 62 from infantile diarrhœa, 61 from measles, 29 from diphtheria, 14 from scarlet fever, and 4 from enteric fever. The deaths from whooping-cough, measles, and diphtheria were the lowest numbers recorded in any week of the current year. The 787 cases of scarlet fever and 961 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 49 and 55 below the respective numbers remaining at the end of the previous week. The 915 deaths from all causes in London included 86 from influenza, against 218, 287, and 192 in the three preceding weeks. The causes of 31 deaths in the 96 towns were uncertified, and included 4 in Birmingham, and 3 each in London and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 14·2, against rates increasing from 11·5 to 17·4 per 1000 in the four preceding weeks. The 318 deaths in Glasgow corresponded to an annual rate of 14·9 per 1000, and included 7 from measles, 4 from infantile diarrhœa, 3 from whooping-cough, 2 from diphtheria, and 1 from enteric fever. The 71 deaths in Edinburgh were equal to a rate of 11·1 per 1000, and included 2 from measles and 1 from scarlet fever.

Irish Towns.—The 153 deaths in Dublin corresponded to an annual rate of 20·0, or 7·2 per 1000 below that recorded in the previous week, and included 5 from infantile diarrhœa, 2 from whooping-cough, and 1 each from measles and scarlet fever. The 131 deaths in Belfast were equal to a rate of 17·4 per 1000, and included 8 from infantile diarrhœa, 2 from whooping-cough, and 1 each from measles and diphtheria.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Criminal Law Amendment Bill.

THE House of Commons has appointed a Select Committee of six Members to join with a Committee of the House of Lords to consider the Criminal Law Amendment Bill and the Sexual Offences Bill. The six Members are Sir WILLIAM COLLINS, Sir WILLOUGHBY DICKINSON, Mr. G. LOCKER-LAMPSON, Mr. NEVILLE, Mr. JOHN O'CONNOR, and Mr. TYSON WILSON.

Workmen's Compensation (Silicosis) Act.

The Royal Assent has been given to the Workmen's Compensation (Silicosis) Act.

HOUSE OF COMMONS.

WEDNESDAY, JULY 24TH.

A Ministry of Health.

Mr. H. SAMUEL asked the Chancellor of the Exchequer whether the Government proposed to introduce before the adjournment a Bill for the establishment of a Ministry of Health.—Mr. BONAR LAW replied: The Committee of Home Affairs has made good progress with the consideration of the Bill, and hopes shortly to get its proposals into shape, but it is not yet possible to say whether the Bill can be introduced before the adjournment.

Mr. WATT: Is the right honourable gentleman aware that such a Bill will not be a non-contentious measure in this House?—Mr. BONAR LAW: If it is introduced I hope that it will be a non-contentious measure.

Captain SHEEHAN asked whether it was intended that Ireland should be brought within the scope of the measure setting up a Ministry of Health.—Mr. BONAR LAW answered: This is not at present proposed, but any suggestion which may be made by Irish Members on the subject will of course receive consideration.

Mr. NUGENT: Has any effort been made to ascertain what is the opinion in Ireland in reference to this question?—Mr. BONAR LAW: As far as I know no effort has been made. As a rule, Irish Members do not require any effort to be made for us to find out what they want.

Mr. NUGENT: Is the right honourable gentleman aware that the Insurance Commissioners have already had communications on this matter, and has any effort been made to elicit the opinion of the people at all?—Mr. BONAR LAW: I am not aware of that.

Influenza in Central Telegraph Office.

Mr. PIKE PEASE (Assistant Postmaster-General), in the course of an answer to Mr. GILBERT, said: The influenza epidemic has been a serious matter in the Central Telegraph Office, where we have had as many as 700 people off in one day.

THURSDAY, JULY 25TH.

Hospitals in France.

Colonel FABER asked the Under Secretary for War whether he would consider the advisability of having the hospitals at the fronts some distance away from fighting units, so that no mistake could possibly arise in enemy bombing operations; whether to assist this object light railways could be laid down by which to remove patients on to the main lines; and whether he would insist on the red cross being plainly painted on our marquees.—Mr. MACPHERSON answered: The measures suggested by my honourable and gallant friend have already been put in hand so far as labour is available. Hospital establishments are clearly marked.

Panel Practice in War-time.

Mr. MORRELL asked the representative of the National Insurance Commissioners whether his attention had been called to the hardship that was caused to panel doctors by the continuous and progressive depletion of their practice during their absence on war service; and whether he was prepared to take any steps in the matter.—Sir E. CORNWALL replied: I am not aware of any general prevalence of the difficulty suggested in the question. Certain steps have already been taken by the Commissioners in regard to it—by means of regulations of which I am sending the honourable Member a copy—in accordance with the suggestions made to them for the purpose by the medical profession.

MONDAY, JULY 29TH.

Dentists in the Army.

Mr. WHYTE asked the Under Secretary for War whether he had now taken the steps promised a month ago to increase the number of dentists serving professionally with the British Expeditionary Force in France.—Mr. MACPHERSON answered: We have increased the number of dentists in this country and are now awaiting the demands of France which we can meet.

Medical Men in Turkey.

Lord H. CAVENDISH-BENTINCK asked the Under Secretary for War what steps had been taken to ensure that the British doctors who were prisoners in Turkey were suitably distributed among the different prisoners' camps; and whether he would arrange that our rights for exchange of doctors under the Berne agreement should be waived, in so far as to allow of at least one British doctor remaining at each camp and at least 1 per 1000 prisoners at camps with more than 1000 prisoners.—Mr. MACPHERSON replied: This matter is under consideration, and I hope that it will be possible to make arrangements on the lines suggested by my noble friend.

TUESDAY, JULY 30TH.

Artificial Limbs and Surgical Appliances.

Mr. HOUSTON asked the Parliamentary Secretary to the Ministry of Pensions whether there was delay in supplying artificial limbs and surgical appliances to wounded and mutilated soldiers and sailors who had been discharged from service, thereby causing pain, suffering, and pecuniary loss which might be avoided; and, if there was no delay, could he explain the many complaints which were made by these gallant and suffering men.—Sir A. GRIFFITH BOSCAWEN replied: There has undoubtedly been delay in the past in supplying artificial limbs owing mainly to the lack of accommodation. During the last two months additional limb-fitting hospitals have been opened at various centres in the United Kingdom, and the services of additional limb makers have been secured. The result will be an immediate reduction in the number of men waiting to be fitted.

WEDNESDAY, JULY 31ST.

Training of Army Nurses.

Major CHAPPLE asked the Under Secretary for War whether the certificate of training presented in evidence of qualification by London hospital nurses applying for posts in the Army service stated that the nurse had had three years' training in the hospital or only two years' training.—Mr. MACPHERSON replied: As I have already informed my honourable friend, steps are always taken to ascertain that a nurse has completed the necessary period of training and service in the wards.

Sir C. HENRY: Is there any differentiation made in this rule as between the nurses who come from the London Hospital and those coming from elsewhere?—Mr. MACPHERSON: No, Sir.

Births, Marriages, and Deaths.

BIRTHS.

LIDDERDALE.—On July 26th, at Belmont Lodge, Cheltenham, the wife of Captain W. Guy Lidderdale, R.A.M.C., of a daughter, who survived her birth only a few hours.

MARRIAGES.

BURNHAM—PATERSON.—On July 23rd, at the Parish Church, Langholm, Cecil Burnham, M.B., Ch.B., F.R.C.S. Edin., Temporary Major, R.A.M.C., Italian Expeditionary Force, to Marion Paterson, third daughter of the late J. W. J. Paterson, Terrona, and Mrs. Paterson, Eskbank, Langholm.

COLLIE—ALDERTON.—On July 25th, at the Chapel Royal, Savoy, Lieutenant Arnold E. Collie, R.A.M.C., son of Sir John Collie, M.D., C.M.G., to Ethel Mary, elder daughter of the late F. F. Alderton and of Mrs. Alderton, of Harrow-on-the-Hill.

SHANNON—KERR.—On July 17th, at St. Andrew's Church, Wells-street, London, Captain F. Shannon, R.A.M.C., to Anne Muriel Shannon Kerr, youngest daughter of the late Rev. R. S. Kerr, Rector of Howth, Dublin.

SHATTOCK—MACKENZIE.—On July 27th, at St. Anselm's, Kingsway, Clement Edward Shattock, M.D., M.S., F.R.C.S., of Wimbledon, to Fede Margaret Mackenzie, M.B., B.S., of Genoa, Italy.

VERNON—ABEL.—On July 25th, at Westminster Chapel, Buckingham Gate, Lieutenant C. H. Vernon, R.A.F. Medical Service, to Edith, elder daughter of Rev. and Mrs. A. E. Abel, of The Manse, Godalming.

WHITE—LAMB.—On July 24th, at Holy Innocents' Church, Fallowfield, Manchester, Charles Powell White, M.A., M.D., F.R.C.S., to Lettice Mary, second daughter of Professor Horace Lamb, D.Sc., F.R.S., of the University of Manchester.

DEATHS.

BATTEN.—On July 27th, Frederick Eustace Batten, M.D., F.R.C.P., of Harley-street, of collapse following operation, aged 52 years.

BEATTIE.—On July 22nd, at Southampton (suddenly), Captain J. W. Beattie, M.D., R.A.M.C.

LESLIE-JONES.—On July 18th, at Fowey, Cornwall, Hudson Leslie-Jones, B.E., M.D., F.R.C.S.I., in his 78th year.

MOORHEAD.—On July 23rd, at Brightlands, Crabton Close, Boscombe, Bournemouth, Lieutenant-Colonel James Moorhead, I.M.S., aged 66 years.

ROBERTS.—On July 28th, at North-gate, Regent's Park, Frederick T. Roberts, M.D., F.R.C.P., B.Sc. Lond., Hon. D.Sc. Univ. of Wales, Fellow of University College, London, Emeritus Professor, Medicine and Clinical Medicine, University College, London, in his 79th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE METROPOLITAN WATER-SUPPLY DURING JANUARY, FEBRUARY, AND MARCH, 1918.

IN the report of the Water Examiner on the condition of the Metropolitan water-supply for the month of January it is shown that the mean rainfall during the month was 3·26 in., being 1·05 in. above the average mean rainfall for that month during the previous 35 years. Compared with the averages for the year 1917, all the raw river waters yielded results on a chemical examination worse than their respective averages, and bacteriological examination showed all three raw waters contained more bacteria than their respective averages for the year 1917. The filtered waters, though comparing unfavourably chemically with those obtained in the corresponding period in the previous year, gave not unsatisfactory results on bacteriological examination, no typical *B. coli* being contained in 100 c.cm. of the samples in the case of 64·8, 18·2, and 58·2 per cent. examined. In February the rainfall was 1·39 in., being 0·65 in. below the average mean rainfall for that month during the previous 35 years. All three raw waters yielded results compared with the previous year better than their respective averages as judged by the usual tests, New River water being an exception which showed no change. On the other hand, the filtered waters showed in some respects worse results than their respective averages. The colour test showed also worse results. Bacteriologically the three raw waters were found to contain fewer bacteria than their respective averages for the year 1917, and the filtered waters were satisfactory. In March the mean rainfall was again below the average mean. It was 1·08 in., being 1·10 in. below the figure for March during the previous 35 years. All three raw waters on chemical examination yielded results better than their respective averages in 1917, and they also contained fewer bacteria. The filtered waters yielded satisfactory results, no typical *B. coli* being found in 100 c.cm. of the water in 97·2, 84·2, and 92·6 per cent. of the samples examined. The general returns show that while with increased rainfall the raw waters give less satisfactory results both chemically and bacteriologically the efficiency of filtration is maintained.

DEATHS FROM INFLUENZA.

FOR the week ending July 20th the Registrar-General's returns show 192 deaths ascribed to influenza in the County of London, as against 67, 218, and 287 in the preceding three weeks, and an average of 5. In Scotland during the same week 19 deaths were credited to influenza, and in 79 deaths classified as due to other diseases influenza was a contributory cause. The figures for the previous week were 26 and 74, and for the week preceding 9 and 27 respectively.

COST OF WAR-TIME PRESCRIPTIONS.

ACCORDING to figures prepared for the London Insurance Committee the average cost of the 3¾ million prescriptions issued during the year 1917 was :—

	d.	
Ingredient cost	2·91	per prescription.
Dispensing fee cost	2·83	,, ,,
Total cost	5·74	,, ,,
Cost per insured person	14·51	
Number of prescriptions per person	2·53	

The average cost per prescription in 1915 was 7·87*d.*, and in 1916, 5·34*d.*

THE RED CROSS AT SEA.

THE concluding lecture of the series on First Aid at the College of Ambulance (3, Vere-street, London, W.) was given on July 18th by Mr. George F. Shee, M.A., secretary of the Royal National Lifeboat Institution, who described the work of the institution in saving life at sea. Miss Helen MacKenzie, one of the organisers of the lectures, presided. Founded in 1824, and now approaching its centenary, the Lifeboat Institution claims to have saved 56,700 lives during its existence, and nearly 5000 since the outbreak of the war. 1500 rescues have been made from war casualties on the sea; from the *Rohilla* alone 85 people, including doctors and nurses, were brought away in the lifeboats of the Institution. Supported entirely by voluntary contributions, the Royal National Lifeboat Institution carries on its work at a cost of £115,000 a year, as compared with the State service of the U.S.A. subsidised to the extent of £450,000 a year, the number of boats being practically the same in each case, about 260. The work of lifeboat men requires courage in no ordinary degree, and Mr. Shee contended that a committee composed of Victoria Cross holders would unhesitatingly admit that the standard of heroism had been raised by the men who brave the perils of the sea in order to save human life.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, August 5th.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Out-patients each day at 2.30 P.M.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY, August 5th.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

Colonel J. G. Adami, C.A.M.C., will deliver a lecture on the Canadian Army Medical Corps and Medical Progress at the meeting of the Medical Society of the C.A.M.C., Shorncliffe, on August 12th. Medical men not members of the society who would like to be present should communicate with the secretary, Major A. H. Pirie, No. XI. Canadian General Hospital, Shorncliffe. At the following meeting in September Sir William Osler will lecture on "The Future of the Medical Profession in Canada."

EDITORIAL NOTICES.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

We cannot undertake to return MSS. not used.

Offices: 423, STRAND, LONDON, W.C. 2.

Communications, Letters, &c., to the Editor have been received from—

A.—Capt. J. E. Adams, R.A.M.C.; Mr. P. W. Atkin, Manchester.

B.—Queen's Univ., Belfast; Dr. J. A. Browne, Newport, Essex; Dr. F. M. Blumer, Stafford; Miss Constance Beerbohm, Lond.; Major Piero Boveri, R.A.M.C.; Messrs. A. and C. Black, Lond.; Dr. T. H. C. Benians; Mr. W. Branton, Leighton Buzzard.

C.—Mr. J. Cabburn, Lond.; Dr. S. D. Clippingdale, Lond.; Capt. John Campbell, R.A.M.C.

D.—Staff-Surg. S. F. Dudley, R.N.

E.—Mr. Arthur Evans, Lond.; Ex-officers' Employment Bureau.

G.—Dr. A. Withers Green, Lond.; Dr. W. Gordon, Exeter; Sir Jas. Galloway, Lond.; Prof. R. A. Gregory, Lond.

H.—Dr. M. H. Hanna, Geneva; Maj. H. Hemsted, R.A.M.C.; Dr. J. Hudson, Newcastle-on-Tyne; Major A. F. Hurst, R.A.M.C.

I.—Mr. R. B. Ince, Jarvis Brook; Insurance Committee for the County of London.

L.—Dr. A. S. Leyton, Oxford; Dr. C. E. Lea, Manchester; Local Government Board, Dublin, Asst. Sec. of; Local Government Board, Lond., Medical Officer of.

M.—Dr. H. A. Macewen, Lond.; Mr. F. S. Miles, Hove; Mr. A. Mercer, Wimbledon; Mr. John Murray, Lond.; Lieut. R. H. Malone, I.M.S.; Col. C. S. Myers, R.A.M.C.

N.—Nat. Baby Week Council.

O.—Capt. E. O'Connor, R.A.M.C.; Dr. T. T. O'Farrell, Dublin.

P.—Dr. L. J. Picton, Holmes Chapel; Miss K. Pilkington, Lond.; Dr. F. W. Price, Lond.; Dr. F. W. Pilkington, Kencott; Staff-Surg. R. J. G. Parnell, R.N.

R.—Mr. H. S. Reynolds, Wisbech; Reg.-Gen., Edinburgh.

The Lumleian Lectures
ON
CŒLIAC DISEASE.

Delivered before the Royal College of Physicians of London on March 14th, 19th, and 21st, 1918,

BY G. F. STILL, M.A., M.D. CANTAB., F.R.C.P. LOND.,
PROFESSOR OF DISEASES OF CHILDREN, KING'S COLLEGE, LONDON; PHYSICIAN FOR DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE I.

MR. PRESIDENT AND FELLOWS,—One cannot but regard it as an honour to deliver before this our College the Lumleian lectures; but one undertakes the duty with some trepidation, being only too conscious that the privilege carries with it the responsibility of upholding the high tradition which has come down to us from the Lumleian lecturers of more than three centuries.

INTRODUCTORY.

The disorder which I have taken as my subject I shall consider under the title of "Cœliac Disease," the name under which it was originally described by a late distinguished Fellow of this College, Dr. Samuel Gee.

In this first lecture I shall deal chiefly with symptomatology, and I shall assume, only as a working hypothesis, and without any intention of prejudging the question, that in the combination of symptoms which has been called by this name we are dealing with a specific disease. In my second lecture, in which I shall consider the pathological aspect, I shall discuss this important question of specificity, and, finally, in my third lecture, I shall consider treatment.

There is little to be said of historical nature owing to the fact that until Dr. Gee's observations[1] were published in 1888 the condition had apparently not been recognised, or, at any rate, had not been described, as a clinical entity. Since that date remarkably little has been written about it, and that little seems to have attracted no general attention, largely, perhaps, because different observers have described the condition under different names.

The late Dr. Cheadle[2] in 1903 included it under the heading of "acholia"; in 1908 Dr. Herter,[3] in America, called it "intestinal infantilism"; and in 1913 Drs. Poynton, Armstrong, and Nabarro[4] published a valuable study of this affection as "A Group of Cases of Chronic Recurrent Diarrhœa in Childhood."

Its rarity also has no doubt had something to do with the scantiness of its literature.

During the past five years at the Children's Hospital, Great Ormond-street, amongst 14,800 admissions of children under 12 years of age there were only 17 cases of "cœliac disease." Figures, however, taken from a hospital do not perhaps altogether give a reliable idea of the frequency of its occurrence, for this is one of those affections which for some reason, difficult to ascertain, seems to be more rare amongst hospital patients than amongst those seen in private practice. I find that of cases under my own observation 17 were seen at hospital, whereas 24 came to me in the ordinary course of consulting practice.

This point may not be without its significance as to etiology, for I think we may safely infer from it that the condition is not one of those specially incidental to poverty or to lack of hygienic surroundings.

Further, inasmuch as the diarrhœa of infancy and early childhood is undoubtedly closely related to both these factors, the cœliac affection presumably is not a mere variation or outcome of the ordinary diarrhœa of infancy.

Dr. Gibbons,[5] in his article on cœliac disease, expresses this view, which I think most clinicians must have held who are familiar with the diarrhœal affections of infancy and early childhood.

He says: "It is distinctly not the disease known as chronic diarrhœa of children." It is, however, easier to make such an assertion than to prove it or even to define exactly what is meant by it. Diarrhœa is a symptom not a disease, and in so far as cœliac disease is both diarrhœal and chronic it clearly is a chronic diarrhœa of childhood; nevertheless, the character of the diarrhœa and the associated symptoms make up a clinical picture which many observers have regarded as something *sui generis*, and have therefore suspected of a specific cause; only when this can be demonstrated will it be possible to say positively that cœliac disease is entirely separable from other diarrhœal affections of infancy and early childhood. In the meantime, if in addition to the characteristic grouping of symptoms this disorder can be shown to have etiological factors which are not common to other diarrhœal diseases, we shall have gone some way towards defining its position.

INCIDENCE.

A remarkable fact which comes out of my own series of cases is the much greater frequency in girls than in boys; out of 41 cases 30 were girls, 11 were boys.

I have no explanation to offer for this, but if it be confirmed by larger figures it raises once again a problem which has always seemed to me exceedingly interesting—namely, the sex incidence of disease. Why congenital hypertrophy of the pylorus or idiopathic dilatation of the colon should occur far more often in boys than in girls, or even why hysteria should be more common in women than in men is mysterious enough, but it seems, if possible, more surprising that an infective condition—if, indeed, cœliac disease is to be regarded as such—or a functional digestive disorder, if that view be more correct, should affect the female so much more often than the male.

The age at onset is, in the majority of cases, the later part of infancy, between the age of 9 months and 2 years. The earliest in my series was 8 months, the latest 4½ years. Only 2 other cases began as late as 3–4 years of age.

Several, however, were first seen by me when they had already reached the age of 3–7 years and the disease had already been present for some years. Indeed, it is by no means easy to be sure of the date of onset in some cases as the disorder may begin quite insidiously. As far as I have been able to ascertain, in no case did the disease begin while the child was still on breast-feeding. In some cases the onset has been with an attack of diarrhœa, which does not seem to have been particularly severe in character, but diarrhœa is not a necessary antecedent, for, as Gee pointed out, costiveness is sometimes a forerunner of the disorder; in three cases there was only vomiting at first. In some the first symptom which seems to have caused anxiety was wasting.

CLINICAL PICTURE.

The clinical picture of "cœliac disease" when it has already lasted for two or three years is sufficiently striking.

The child is pale and emaciated, although, as Gee observed, the face sometimes remains full and apparently plump even at a late stage of the disease. The large abdomen contrasts with the wasted limbs, and the general appearance is that of tuberculous peritonitis, for which cœliac disease is apt to be mistaken. The most striking feature is the surprising inconsistency of the child's size with its age. What appears to be an infant little more than 12 months old startles one by unexpectedly talking, and so reveals the fact that it is at least a year or two older, perhaps 3 or 4 years older, than its appearance would suggest.

On inquiry it is found that the child's stools, though not more than one or two a day, have almost never been formed since the illness began, and that they are generally pale or the colour of oatmeal. At intervals of a few weeks the stools become more loose and frequent, perhaps three or four a day instead of one or two. These recurrent bouts of increased looseness are very characteristic of the disease.

The weight, moreover, though it fluctuates, has made no permanent advance for many months, or even for a year or two; and the net outcome of its variations may even have been a loss of 2 or 3 ounces in as many years.

So the disease drags on for months and years.

Wasted and feeble, the child passes an invalid existence with intervals of improvement followed by a relapse, until, as a result of rigorous dieting, the stools gradually became more normal, and the child eventually struggles back to health, able to take food more or less like other people, but handicapped in growth by the lost time during which the development has been arrested. Even such a favourable result, however, is not to be expected in all cases, for the relapses with increased looseness of the bowels are exhausting, and may end fatally.

SYMPTOMS.

From this preliminary sketch of a case of "cœliac disease," I pass to more detailed consideration of the symptoms.

Diarrhœa.—The early history of these cases is obviously of importance in determining the pathology of the disease.

In a considerable proportion, 8 out of 20 of those in which the onset was more or less defined, there was a history of an attack of diarrhœa with or without sickness at the onset, and since then the stools had never been normal except occasionally, perhaps, for a day or two.

Prima facie this sequence would suggest that the initial diarrhœa and the subsequent looseness of the bowels and recurrent exacerbations of looseness, were due to an infection which had never been entirely thrown off by the bowel, and it might even be conjectured that any diarrhœa of infective origin might lead to such a disorder.

On this account I want to lay stress particularly upon the fact already noted, and particularly observed by Dr. Gee, that diarrhœa is not a necessary antecedent. In 3 out of those 20 cases the mother declared that the bowels had "always been loose"; there was no particular attack of diarrhœa. In 4 out of the 20 the onset had been entirely insidious, with wasting, and in one at least of these there had been constipation at first, with wasting, until after weeks or months the bulky and pale character of the stools and their looseness became pronounced.

Infantile scurvy.—A curious fact which appears in my series of cases is the occurrence of "infantile scurvy" as the antecedent of "cœliac disease" in a proportion of the cases, too large, I think, to be entirely accidental; 4 out of my total series of 41 cases had "infantile scurvy" just before or during the onset of "cœliac disease."

Inasmuch as infantile scurvy is also a comparatively rare disorder, its association as an antecedent with cœliac disease in a proportion so high as nearly 1 in 10 is at least noteworthy. I would mention here, as a possibly correlated fact, the ease with which these children fall victims to scurvy as a result of the diet used for the treatment of the disease. It may be that infantile scurvy conduces in some way to diarrhœal affections; certainly experience teaches caution in its treatment on account of this particular tendency. Quite apart from the fact that the passing of blood from the bowel in scurvy shows that the mucosa is in some way affected, there are clinical phenomena which suggest very strongly that the deficiency of vitamines which produces scurvy produces also a lowered resistance to infection. It may be that in this way the food factors which lead to scurvy predispose also to cœliac disease.

Stools.—Quite early in cœliac disease the stools show characteristic qualities:—

They are bulky, pale, creamy, unformed, pultaceous, resembling more or less closely well-boiled porridge, except that they look more glistening and greasy than porridge does; the smell, too, is very offensive, fatty and sour, perhaps rancid best describes it; the reaction is markedly acid and the stool floats in water.

But while such is the typical stool I would point out that there is much variation from time to time; sometimes for a few days the stools are pale yellow, or even brown; sometimes they are white and shreddy; occasionally the child will pass a formed stool, differing little from the normal except in its pale drab or fawn colour.

A point, however, which I think has not been sufficiently recognised is the change in the character of the stool which tends to occur as the disease becomes of longer standing.

The white porridgy stools which were usual during the first year or two of the illness become less and less a constant feature until the evacuations quite as often consist of shreddy or soft fæcal material pale grey or greenish or even dark brown, mixed with mucus, which in rare instances may even show a trace of bright red blood. In one advanced case pus was found in the stool, during one of the bouts of looseness. Occult blood has been found occasionally even in the earlier stage of pale porridge-like stools.

In some cases the parents themselves have particularly noticed the change in the character of the stools after the disease has lasted some years. I lay some stress upon this point not only because the absence of the typical porridgy character of the stool might mislead diagnosis in an advanced case, but also on account of its probable bearing upon the significance to be attached to changes found in the bowel at post mortem. It suggests that lesions found at that stage may be of secondary origin; I mean that inflammatory and perhaps ulcerative changes in the lower part of the bowel may be secondary to unhealthy conditions in the upper part.

With the unhealthy condition of the stools there is associated distension of the abdomen, which forms one of the characteristic features of the disease. In cases that do badly this sometimes becomes so extreme as to cause considerable distress to the child before the fatal termination; in cases that do well it is one of the last symptoms to disappear.

The *absence of vomiting* in most cases, except as an uncommon incident, seems to indicate that the condition is rather an intestinal than a gastric disorder.

Pain there is usually none, and when it has been present has been only a slight transient discomfort such as might be produced by flatulence. To this statement exception must be made of the severe pain which has occurred a day or two before death; this was noted by Drs. Poynton, Armstrong, and Nabarro in their fully recorded fatal case, and autopsy showed no explanation of the pain. It occurred also in a girl under my observation, but no autopsy was made, so its cause was uncertain.

Cœliac disease is not accompanied by fever.

Urine.—The urine I have examined in many cases without finding anything abnormal.

Having regard to the extremely offensive smell of the stools, one might have expected to find indican present in considerable quantity, and sometimes this has been observed; it is not, however, a constant feature.

In one case a trace of albumin was present in the urine at repeated examinations; in another, a girl in whom the disease had been present for nearly six years, there was a considerable cloud of albumin and some hyaline and granular casts, evidently indicating a certain degree of actual renal irritation, though there were no other symptoms to point to it. There is nothing surprising in this when one remembers that slight albuminuria is no great rarity with intestinal disorders, particularly diarrhœal affections, in infancy and early childhood. It is perhaps only remarkable that with such persistent disorder, associated for years, as I shall show, with evidence of toxæmia, there should not more often be evidence of renal irritation.

Liver.—There is no enlargement of the liver. I have thought, indeed, that the reverse is rather a feature of the disease.

The edge of the liver is usually not to be felt below the costal margin. Considering the frequency with which the liver is easily palpable in children, especially in those under 5 years of age, one is the more struck by the failure to feel it at all in a large proportion of cases of cœliac disease. Whether the organ is actually diminished in size is difficult to ascertain by clinical examination. I have tried in some cases to settle this question by percussion, and I show here some figures which prove that at any rate the hepatic dullness is diminished.

Vertical Measurements of Liver Dullness in Right Nipple Line.

Cœliac.		Normal.		Cœliac.		Normal.	
Age.	Liver.	Age.	Liver.	Age.	Liver.	Age.	Liver.
—	—	9 wks.	4·25 cm	3½ yrs.	4·5 cm.	3½ yrs.	11·5 cm.
—	—	8 mths.	7·5 ,,	—	—	5 ,,	8·5 ,,
—	—	16 ,,	5·75 ,,	—	—	6 ,,	8·5 ,,
—	—	21 ,,	9·0 ,,	6½ yrs.	6·5 cm.	6½ ,,	9·25 ,,
3⅓ yrs.	4·5 cm.	3½ yrs.	10·0 ,,	7 ,,	4·75 ,,	7 ,,	9·5 ,,
3¼ ,,	4·25 ,,	3½ ,,	9·5 ,,	8 ,,	5·5 ,,	7 ,,	7·0 ,,

I shall refer to this again in discussing the pathology of the disease: here I should like to mention that it is one small point in the diagnosis from abdominal tuberculosis and syphilis, in which the liver is more often easily palpable.

The *spleen* also is usually not to be felt, a fact which may be of importance if the possibility of congenital syphilis is in question, and I shall later mention observations which would seem to render this question pertinent.

Blood changes.—The pallor, which is always a more or less marked feature of the disease, is found to be associated chiefly with a deficiency of hæmoglobin in the blood, but not of any profound degree.

In a severe case, a girl aged 3½ years, the count was as follows: Red blood corpuscles, 3,450,000; white cells, 12,500; hæmoglobin, 50 per cent.; colour index, 0·7. Differential count per cent: Polymorphs, 59·5; lymphocytes, 35; large mononuclear, 2; basophiles, 0·5; transitionals, 3·0; no abnormal cells.

Another, a girl aged 6½, showed red corpuscles 4,500,000, white corpuscles 15,625, hæmoglobin 58 per cent., colour index 0·6. Differential count per cent.: Polymorphs 70·5, lymphocytes 26, large mononuclear 0·5, eosinophiles 0·5, basophiles 0·5, transitionals 1·0, one normoblast in 200 cells.

In another, a girl aged 5¼, the red corpuscles were 5,300,000, white cells 8750, hæmoglobin 40 per cent., colour index 0·3. Differential count per cent.: Polymorphs 45, lymphocytes 49, large mononuclear 5, eosinophiles 1.

In all these cases there was marked pallor, so that one was surprised at the slightness of the blood changes. This absence of any profound disturbance in the blood is particularly noteworthy in relation to the occurrence of œdema, to which I shall refer later; presumably we must look elsewhere than to hydræmia for an explanation of this symptom.

The only constant blood change shown by these few observations is deficiency of hæmoglobin, a change which may be related to the failure of fat absorption, which, as I shall show, is one of the features of this disease; for it has been shown that a similar picture results from the experimental use of a diet very deficient in fats. A pig fed thus showed after many weeks only 65 per cent. of hæmoglobin, whereas the blood cells were only very slightly reduced in number. (Herter.[6])

The *arrest of development* is one of the most striking features of the disease, and this is not merely a cessation of gain in weight but also a cessation of growth, a point which distinguishes it from the atrophic conditions which result from various disorders of digestion in early life.

It is common enough for an infant to become thin or even emaciated with evident symptoms of indigestion and unhealthy stools and to suffer in this way for months, and yet at the same time to grow even rapidly in length, whereas, in the child with cœliac disease growth in length seems to be arrested from a very early stage, if not from the onset, of the illness. Moreover, it is clearly not dependent entirely, if at all, upon the general failure of nutrition, for months after increase in weight has been established there is still little or no gain in length; this seems to come later.

The following figures will give some idea of the deficiency in weight shown by these children.

A girl aged 23 months, when the weight should have been 27 lb., weighed 7 lb. 2 oz.

Another at the age of 3 years 5 months weighed 14 lb., the weight of a child of 5 months.

A girl aged 5½ years weighed 21 lb., the average weight of an infant of 12 months.

The arrest of growth in height can be appreciated from the following measurements.

The girl mentioned above, aged 3 years and 5 months, measured 33 inches in length, instead of the normal 36 inches.

Another at 5 years was 33 inches; the normal at this age is 41 inches.

Another at 6 years was 37½ inches (6 inches below the normal), the height of a child of 3½ years. Her sister, a healthy but unusually tall child of 2½ years, was said to be exactly the same height.

A girl, aged 17½, was 55⅜ inches, the height of a child of 12 years.

As the arrest of growth in stature has been attributed to deficient assimilation of calcium consequent upon the failure of fat absorption, it seemed worth while to investigate the condition of the bones by X ray examination to see whether any failure of calcification could be detected.

I had skiagrams taken of the limbs in three cases. In all these cases the bones were unduly small, corresponding to the small stature of the child, but none showed any abnormality in the formed bone, the trabecular structure was well marked and the outer layer appeared to be normal in thickness and density. They all showed, however, a marked departure from the normal for the age in respect of the centres of ossification in the epiphyses. These corresponded not to the real age of the child but to that of one much younger, roughly one might say to the apparent age of the patient.

There is in these skiagrams a notable absence of the usual appearance of rickets, a fact which seems to show that if deficient calcium absorption is the cause of the arrested growth in cœliac disease, then something further is necessary to the causation of rickets.

A noticeable feature, which no doubt is to be explained as part of the arrest of growth, is the smallness of the voice in most of these cases.

It tends to high pitch and very limited compass, characters due probably to the smallness of the larynx. This feature, however, is in curious contrast with the rather gruff voice which obtains in some other conditions where growth is delayed—for instance, mongolism and cretinism.

One might have expected that there would have been delay in dentition as one result of the general interference with nutrition.

This is so to some extent, but not to any such marked degree as one might have expected from the delay of development in other respects.

In one case, where the disease began at 9 months, there were only six incisors and three molars at 22 months, and in other cases, where

the disease had begun at about a year old, I have noted that only 12 or 13 teeth were present at the age of 2 years.

The delay is not due to any accompanying rickets. It is, indeed, a remarkable fact that rickets is rarely found in spite of the long-enduring disturbance of nutrition produced by cœliac disease.

Muscular feebleness.—Gee and most other writers have drawn attention to the muscular feebleness of these children.

One of my cases, mentally normal, perhaps indeed rather precocious, was not able to walk until she was 6½ years old. Another, in whom the disease began at 1 year, first stood alone at 3 years and 8 months.

Dr. Gee says that even when recovery tends to be complete, a peculiar weakness of the legs is left long after all other tokens of disease have passed away, a weakness which shows itself in that the child is unable to jump.

The *mental capacity* of these children does not seem to be affected.

They remain capable of as much development ultimately as other children, but in the meantime they show rather the mental development which is normal for a child of their size than that which is normal for a child of their age.

Apart from this the intelligence is, at least, not impaired by the disorder, nor are dull or imbecile children particularly liable to it; indeed, there is not one such among my series of cases.

Whilst, however, the intelligence is quite good in these children they often show a curious slowness in response, as if they weighed one's question carefully before replying. I have thought that this was most noticeable when, with much wasting there was marked pallor, and it seems reasonable to suppose that such a condition must exercise some effect upon the brain as upon other tissues.

As a result of the general weakness the child is usually very quiet and apathetic, taking but a languid interest in toys and picture books.

With improvement in the stools, however, the child soon begins to take more interest, though for a long time, even for some years in cases, it is quieter and less vigorous in its movements than a healthy child.

There is one subject in which almost all children with cœliac disease show a pathetic interest—namely, their food; often, indeed, it is their one subject of conversation, and this is hardly to be wondered at in view of the meagre dietary which forms a necessary part of the treatment, not for weeks but for years.

Complications.—In the course of the illness various complications are apt to arise. One of the most frequent—so frequent, indeed, as almost to be a symptom of the disease—is *œdema* more or less general, though seldom of more than moderate degree.

It is most notable usually in the hands and legs and feet, but the face also has a puffy appearance, especially about the lower eyelids. As part of this dropsy there is sometimes a definite ascites, and this may be more obvious than the slight general œdema. In one case under my observation it had led to a diagnosis of tubercular peritonitis of the ascitic form, for which laparotomy was to have been performed on the day following that on which I saw the child.

Tetany occurred in 3 of my series.

In one case it occurred after the disease had been present about six months, in another after it had been present two years, in another after it had been present about eight years.

In this last case, the girl of 17½ whom I have mentioned before, the tetany recurred for several years and at times it came on almost daily in the afternoons, and at one time the pain was so severe that it was necessary to give chloroform.

Purpura occurred in several cases.

In some it occurred as part of the terminal condition when emaciation had become extreme and such a development might be expected, but in others patches of purpura appeared when the child was rather improving than otherwise, and was well enough to be up and about.

In one girl, for instance, purpura appeared many times from the age of 2½ until the child died of the cœliac disease at the age of 9½ years.

In another patches of purpura were still occurring when the boy had improved so much that he was gaining weight rapidly and had already become fat; a clear proof that the purpura is quite independent of emaciation.

A complication due rather to the treatment than to the disease was *scurvy*, which occurred in 5 cases between the ages of 3 and 7 years. In 2 of these there had been scurvy also preceding the onset of the disease.

The first evidence of scurvy is usually pain in the limbs, and with the knowledge that the diet used for the treatment of cœliac disease is very deficient in antiscorbutic elements the cause of the pains can be recognised early and obviated by relaxing the strictness of the diet either by allowing potato or by increasing the allowance of fruit juice if any has already been given.

But I have seen other cases in which there was complaint of pains in the limbs which did not respond to antiscorbutic treatment and which remained obscure in their origin. One wonders how far these pains may be related to the low proportion of fat allowed in the diet. Certain fats, including milk fat, contain, as recent observations have shown, a vitamine which, though differing in its effects from the antiscorbutic vitamine, has important effects on growth and nutrition. The pains seem to be referred to the bones of the limbs. Is it possible that they are an early symptom—usually not carried further—of those changes which have been miscalled late rickets? I mention this because in one of my cases this complication actually developed.

The patient, a girl, had been kept for four years on a diet containing a minimal proportion of fat and was apparently recovering from the cœliac disease when, at the age of 8 years, her legs began to bend rapidly, so that much distortion occurred, crippling the child.

In one case only, the case in which the disease was still present at 17½ years, there was a *chronic glossitis*.

The tongue was completely bald, almost glazed, with deep fissured ulcers at its margin; it was so sore that at times the girl was unable to eat solids, and the soreness and ulceration had been present in greater or less degree for some years. The only affections of the tongue which I have noted in other cases were in two a tendency to ordinary aphthous ulcers, and in one annulus migrans.

SIMILARITY TO SPRUE.

I would lay some stress upon this occurrence of severe chronic glossitis, for it bears upon a point which I want to consider now, the resemblance of cœliac disease to sprue.

It seems to have been taken for granted by Dr. Gee that there was not merely resemblance but identity. In his original paper he says: "Sometimes from India Englishmen return sick with the cœliac affection," evidently referring to the condition known as "white diarrhœa" or sprue.

Dr. Cheadle, without committing himself to their identity, was evidently inclined to group them both in his category of "acholia." "The condition," he says, "of the stools in the two forms is absolutely identical, some of the symptoms, notably the appetite for food, are different."

There are obvious points of similarity:—

Both are characterised by looseness of the bowels, which persists usually for years; in both there are recurring exacerbations of the looseness; in both the stools are bulky, pale, whitish, usually acid, peculiarly offensive, and on analysis show excess of fat.

In sprue the small size of the liver has been specially noted by Dr. Charles Begg.[7] "The liver dullness," he says, "is always diminished in a pure case of sprue, often greatly so, and this is one of the diagnostic signs of the disease." I have already pointed out that this is noticed in cœliac disease also. In both there is marked abdominal distension with much general wasting and feebleness; both disorders are free from fever. The one symptom which seemed lacking to complete the resemblance is the sore tongue which is so characteristic of sprue. It was not until I came across the case just mentioned that I found that this feature also occurs in cœliac disease as well as in sprue.

The remarkable sex incidence of cœliac disease may be another point of resemblance.

Some observers state that sprue has no special sex incidence, but Mense,[8] in his handbook of tropical diseases, quotes two Dutch writers who independently state that females are much more prone to sprue than males, and Jefferys and Maxwell, in their "Diseases of China" (1910), say "the female sex is far more predisposed to this disease than the male sex."

Amongst my cases is one which is at least noteworthy in this connexion. The child was born in India, where at the age of 9 months she began to suffer with cœliac disease, which she still had when she first came under my care at the age of 5½ years. The child was a most typical case of cœliac disease; the mother was at the same time ill with sprue, also acquired in India, and was under treatment by some of the authorities for tropical disease.

Clearly the identity of these disorders cannot be affirmed until a specific cause common to both has been established, but in the meantime the clinical resemblance is, I would submit, sufficiently striking to justify raising the question.

PROGNOSIS.

The course of cœliac disease is always slow and tedious. I have never seen a case in which complete recovery could be said to have occurred until at least a year or two had elapsed since the onset. It is, however, impossible to assign any exact date of recovery, for it is only very gradually that the ability to digest ordinary food is restored and therewith the stools resume a normal character, and even then there remains for a long while the stunted growth.

As happens with most diseases which last for years, these cases tend to pass out of the care of one medical man to that of another, so that it is difficult to keep track of them, but such records as I have been able to obtain are sufficient to show how protracted this disease may be.

One girl, in whom the symptoms dated from about 9 months, weighed 21 lb. at 5¾ years, and was only improving at the age of 6¼, and died at about 9 years of age.

Another, in whom cœliac disease began at about 20 months old, was seen by me at intervals with relapses following temporary improvement until she died with an exacerbation of looseness and with distension of the abdomen at the age of 9½ years.

Another, a boy, who had been under treatment for cœliac disease from about 12 months of age, died when 8 years old.

Sometimes a fatal result comes earlier, a girl in whom the symptoms appeared at 21 months died of cœliac disease at 4 years.

Another girl in whom the disease began just under a year old died at the age of 21 months, but in this instance the termination was due apparently less to the disease than to an accidental complication, bronchopneumonia; and in another, a girl who had been under treatment for cœliac disease since the age of 14 months, a fatal ending at 2¼ years was due to a streptococcal pharyngitis which could only be regarded as an accidental occurrence.

These 6 cases out of the 41 under my own personal observation are the only ones that I know to have ended fatally, and if it is allowed that in 2 of these death was due to accidental complications rather than to the cœliac disease, it will be seen that it is at any rate a disorder that does not lead rapidly to a fatal ending. On the other hand, the proportion of cases in which complete recovery can be affirmed is not large.

In this same series only five could be said to have recovered in the sense that the stools were as regularly normal as those of a healthy child, and no special restrictions as to diet were any longer necessary, but all these five cases, though they had regained a good state of nutrition, had not nearly attained a normal height and looked years younger than their age.

The active phase of the disease had lasted, respectively, 2 years, 3½ years, 4 years, 4 years, and 6 years before this degree of recovery had been reached.

Each case was under my observation for a year at least and most of them for several years after the recovery, so that it would appear to be permanent.

There are other cases in which after long-continued treatment a sort of *modus vivendi* is reached, which, though it cannot be called recovery, might perhaps be described as permanent improvement.

I had almost described it in the late Sir James Goodhart's words as "Safe, but not sound," but I doubt if it can be regarded as altogether free from risk. The child's nutrition has steadily improved, it is able to take an ordinary diet with little or no special restriction. The stools, though normal in colour, are seldom formed and easily become loose; moreover, growth, though taking place, is unduly slow, and the child, though taking her part in ordinary child life, does so with more effort and is more easily fatigued than other children. Three of my series had recovered to this extent; one of them already referred to when last seen was 17½ years old.

Is there ever complete recovery in the sense of attaining eventually average height and acquiring normal puberty development?

With the exception of the one case which I was able to see at the age of 17½ years, in which neither of these conditions was fulfilled, I have not been able to watch any case sufficiently long to answer this question. I can only mention from hearsay two instances, one a boy and the other a girl, under treatment, I believe, by Dr. Gee and Dr. Cheadle for cœliac disease in early childhood, who in adult life were of at least average stature and seemed normal in every way. I have no knowledge, however, of the girl's menstrual history.

Two cases which I was able to feed on human milk have made so much better progress in growth than is usual in cœliac disease that they bid fair to reach at least an average height.

STUDY OF AN OUTBREAK OF BACILLARY DYSENTERY.

BY G. S. BUCHANAN, C.B., M.D. LOND.,
TEMPORARY HONORARY LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

AN outbreak of bacillary dysentery in an institution in the eastern counties in December and January last, described below, presented the following features which seem worthy of record: (*a*) sudden onset and brief duration; (*b*) evidence that the infection was water-borne; (*c*) the infecting agent was in all cases *B. Shiga*; (*d*) evidence of the persistence of Shiga bacillus when experimentally introduced into water and food; (*e*) noteworthy results of agglutination tests when applied both to dysentery convalescents and to those who had presumably been exposed to infection but had escaped illness.

Account of the Outbreak.

The institution in question was occupied by men engaged mainly in agricultural work in the neighbourhood.

At Christmas, 1917, there were about 360 men in this institution, all but three of whom had been there for two months, most of them since the building was taken into military use in August, 1917. The men had been selected as fitted for farm work; they were well nourished and in thoroughly good physical condition, and the sickness among them before Christmas, 1917, was negligible. The three later arrivals were healthy men, and no suspicion of previous dysentery arose in their case.

This institution stands in open country a mile or more from the nearest village. First built as a local workhouse, it was afterwards used as a home for inebriate women, and later for imbecile children. Its accommodation and arrangements were ample for the number of men for which it was used; it had fairly recently been supplied with a water-carriage system of drainage, and had its own water-supply from a deep well situated close to the main building, drawing water from the chalk at a level of about 100 feet from the surface. The institution was kept in a very cleanly condition, and sanitary discipline was well maintained.

As soon as the outbreak in question was reported, expert inquiry was arranged for, and was carried out by Captain B. Sweeten, R.A.M.C. (S.S.O. of the area), Captain J. D. Benjafield, R.A.M.C. (bacteriologist of the area), Captain S. Shepheard, R.A.M.C. (T.) (appointed to act as resident medical officer in view of his special experience of dysentery), and Captain A. C. Inman, R.A.M.C., who undertook a series of special investigations on agglutination tests by arrangement with the Medical Research Committee at the No. 1 Research Laboratory, St. Bartholomew's Hospital. Measures for prevention, treatment, and research were most thoroughly carried out by these expert officers, while the unsparing activity shown by Captain L. Cranmer-Byng in taking all the measures which were advised or were practicable to deal with the outbreak and trace its cause was of the greatest value.

Occurrence of cases.—Setting aside a few merely suspicious or slight cases, definite dysentery symptoms occurred in 38 cases at dates which may be grouped as follows:—

4 days,	Dec. 27th to Dec. 30th	... ...	12
4 ,,	,, 31st ,, Jan. 3rd	... ...	12
4 ,,	Jan. 4th ,, ,, 7th	... ...	7
Between ,,	8th and ,, 16th	... ...	7

Clinical characters and treatment.—The cases, particularly those which occurred in the first eight days, were of considerable severity, two dying among those first attacked.

Clinically they were typical of bacillary dysentery. At the outset the civil medical practitioner in charge thought that the men were suffering from some form of food-poisoning, and it was not until some days later, when the outbreak had been reported to the A.D.M.S. of the district, that the diagnosis of dysentery was made on clinical grounds and specimens were forwarded for bacteriological examination to Captain Benjafield at the district laboratory. On Jan. 10th Captain Benjafield telegraphed that Shiga bacillus had been isolated from the fæces of two cases, and later this bacillus was recovered from seven other cases. In all instances the bacillus was typical *B. Shiga*, no other dysentery or dysentery-like organism or entamœba cysts being present.

The cases were treated in a special section of the institution, with separate latrines and washing arrangements. Nursing orderlies were provided. Milk, stimulants, and other special medical requirements were requisitioned and supplied. As stated above, a medical officer with special experience of dysentery was put in charge of the cases; for a brief period before his arrival another medical officer had been sent to assist the local practitioner who is in medical charge of the institution. Antidysentery serum was used where required.

All the 36 non-fatal cases had completely recovered by March and no relapses occurred. The cases were kept in the separate section of the institution until satisfactory bacteriological reports had been received. These related to three specimens of fæces taken during January, February, and March. By April the examinations made in Captain Benjafield's laboratory showed that all the 36 cases had given three consecutive negative results, including those in which *B. Shiga* was originally found.

Causation of the Outbreak by Water-infection.

Two circumstances attracted special attention—the sudden onset and short duration of the outbreak (24 cases within 8 days and 31 out of the total of 38 within a fortnight), and its widespread distribution among the men.

The institution is a two-storey brick building enclosing two main courtyards. It comprised 18 dormitories, 16 of which were occupied. Cases occurred in no fewer than 12 dormitories. There are several different mess-rooms and cases occurred in each mess. The 12 cases which occurred in the first four days were as scattered as the subsequent ones. There were three sets of latrines in different parts of the building, but the cases were not restricted to the users of any one of these latrines.

These facts made it certain that there was some one cause operating in regard to the whole institution about the end of December, the infecting agent persisting at most some two or three weeks. No source of infection was to be traced in the district. Shiga dysentery is unknown in this part of the country, and inquiry at farms where the men had been employed gave no indication of any local prevalence of suspicious diarrhœa or illness. It had to be assumed that infection had either been accidentally introduced from outside and had caused one or more unrecognised cases which had subsequently infected their fellows, or that a similar general infection had been started through some one or more of the men having suffered from dysentery before their arrival in England and remaining Shiga bacillus carriers.

These alternative hypotheses of the initial introduction of infection will be discussed later on, but in either case it was necessary to find a common distributing agent, such as food or drink, by which, given the initial infective agent or person, the outbreak itself was produced. Mere case-to-case infection contracted from latrines, or infection locally operating in particular dormitories or messes, were ruled out. There were no flies about at this time of year.

The various articles of food and their preparation and temporary storage were gone into in detail. The cooks, who cooked for the whole institution, were five men who had been there from the beginning, were perfectly healthy throughout, denied ever having had dysentery, and in all cases gave negative agglutination reaction. There were no

other men who handled all the food supplied to the different messes. Moreover, there was a control population, 80 in number, living separately from the institution, but receiving food from the same bulk supplies, all of whom escaped attack.

The facts, on the other hand, were consistent with a general infection of short duration through a temporary specific contamination of the water-supply.

Investigation of water-supply.—The liability of the well to contamination of excretal origin, and the special risk to which this water was exposed just before the outbreak began, is shown by the following considerations:—

1. Leaks were found in drains laid close to mouth of well, some leaks between 6 feet and 13 feet from the well being in a drain which served one of the principal latrines. The soil about these leaks was much blackened, and the possibility of this sewage reaching the water could not be excluded, although it is right to state that the drains themselves traversed a cap of clay which overlies the chalk and that the inside of the well did not show a point of leakage in any part of its wall near the surface.

2. On Dec. 14th the main pump of the well broke down, and it was necessary to use a small auxiliary pump at the bottom of the well just about the water level. As a result the man in charge of the water-supply had frequently to go down the well to see to the engine. This man has also the duties of supervising the sewage disposal plant, and so there was some opportunity of his contaminating the water with sewage-contaminated soil on his boots. This possibility, to which Lieutenant-Colonel D. Harvey first drew attention, was confirmed on detailed inquiry. It was also possible that dry refuse brought to the fire of the pumping-engine might have been swept into the well.

3. The water from the well is probably in underground communication with a disused well in the neighbouring courtyard (a capstan well which could be worked by hand). This capstan well was taken into use as a supplementary supply on one day only (Dec. 16th), following the breakdown referred to. It was clear from subsequent examination, however, that its water was subject to gross pollution from the drain of the laundry adjoining it and also from other badly-laid drains in the same courtyard. Thus, on the days immediately preceding Dec. 27th, when the outbreak began, there had been much disturbances of the water in this ordinarily disused well, sufficient, in all probability, to influence the quality of the underground water being drawn upon by the main well.

4. Analytically the water gave evidence of sewage contamination. On Jan. 8th coliform bacilli were found present in 0·1 c.cm. and absent in 0·01 c.cm. in the water of the main well; a previous examination on August 6th, 1917, had given the same result. After the uncovering and reconstruction of all the leaky drains referred to, another sample was taken on April 26th, 1918, with result of finding coliform bacilli greatly reduced, being present in 10 c.cm. but absent from 5 c.cm. Similar contamination and similar improvement as a result of the drainage work were established in the case of the capstan well.

Thus, looking at the matter generally, it is clear that, given a person at the institution who was excreting *B. Shiga*, there were several ways in which the general water-supply could have become specifically contaminated at the time in question, although the exact manner cannot be conclusively proved.

Duration of the infectious ability of the water.—It should be added that the water-supply was chlorinated towards the end of January, when the epidemic was shown to be probably due to water. The introduction of chlorination did not coincide with the cessation of the epidemic, which had ceased before this. It was, however, to be expected that if the specific infection of the water had been acquired only on a few days at the end of December and had not been renewed, its infecting property would naturally disappear in a comparatively short time. In this connexion some experiments were made by Captain Benjafield by purposely contaminating some of the well water in question from Shiga bacillus cultures and observing the time during which they could be recovered. The bacilli were present, though in greatly reduced numbers, on the tenth day after the contamination, when the observation ceased.

Source of the Initial Infection.

Details of the very thorough and careful search made for an original carrier case, or for evidence of an original introduction of infection from outside, need not here be given, as the results were negative. Only four of the men gave any history of past illnesses pointing to dysentery. In each case the attack had occurred more than a year previously. In none of them was there any history of relapses or any indication from the agglutination test that they had suffered from dysentery.

Incidentally to these inquiries it became necessary to test whether *B. Shiga* could survive for a few weeks on food which had been handled by a dysentery case or carrier.

Some experiments were made on this point by Captain Inman. The freshly cut surfaces of two pieces of bacon and four pieces of various kinds of sausage were lightly streaked with a camel-hair brush wetted with a saline suspension of *B. Shiga*, so diluted as to appear just turbid to the naked eye when held against a dark background. After this artificial infection the foodstuffs were left at ordinary temperature for three weeks. At the end of that time the Shiga bacillus was readily recovered from one portion of bacon and two of the sausages.

Agglutination Results.

Towards the end of January it was arranged that specimens of blood from all the convalescent cases of dysentery then being isolated at the institution should be sent to No. 1 Research Laboratory for examination.

Throughout these investigations the bloods were tested with standard agglutinable cultures of *B. dysenteriæ* Shiga prepared at the Department of Pathology, University of Oxford, on behalf of the Medical Research Committee. The technique employed was that outlined in the directions issued with the standard cultures. In each test the end-point of agglutination (standard agglutination) was arrived at by the use of the reduction table published by Dreyer and Inman.[1] The reaction was regarded as positive if the serum contained 10 or more agglutinin units per c.cm. of serum.

The results of these tests, which are shown in Table 1, are striking. A positive agglutination reaction was obtained in every one of the 35 cases in which blood could be examined, and the high dilution in which the reaction was obtained in nearly all cases is noteworthy.

Serum Agglutination Reactions (Capt. A. C. INMAN, R.A.M.C., *Medical Research Committee*).

S.A. units = Standard agglutinin units per c.cm. of serum.

In addition, blood specimens were taken from a considerable series of men who had not suffered from dysentery (all the dormitories and messes being represented), with the somewhat striking result that as many as 21 out of 114 of such men (18 per cent.) showed an agglutinating power of more than 10 standard units per c.cm. of serum (Table 2). In this 18 per cent. the titre was lower than that of the actual patients, but nevertheless was of an order which is obviously of significance and requires explanation.

TABLE 2.—*Men who Escaped Dysentery.*

114 men examined. I. Reaction negative: 93 men, including cooks (5). II. Reaction positive: 21 men (18 per cent).

TABLE 3.—*Men from Similar Institutions where No Dysentery Occurred.*

104 men examined. I. Reaction negative: 103 men. II. Reaction positive: 1 man (0·9 per cent.) in dilution 1 in 37. Standard agglutinin units per c.cm. of serum, 15.

In view of the possibility that the reaction of these 21 men might in some way have been determined by a previous inoculation, inquiries were made on the point both in their case and in the case of a similar number of controls showing no reaction.

[1] THE LANCET, March 10th, 1917.

The facts in each group, however, were practically identical. No special history could be obtained pointing to any of them having been inoculated with an antidysentery vaccine. All had received what appeared to have been an antityphoid inoculation early in 1917, the 21 cases in no way differing from the controls in this respect.

By way of further test, arrangements were made to supply Captain Inman with corresponding blood specimens from healthy men under comparable conditions in other institutions where no dysentery had occurred. 104 such blood specimens were taken, with result that in one case only was there any evidence of a high agglutination—namely, a single case showing 15 standard agglutination units per c.cm. of serum.

These results suggest the explanation that the 18 per cent. of the healthy men at the institution had acquired the ability to agglutinate *B. Shiga* as a result of exposure to the same infection which had produced dysentery in the 38 men who suffered from the outbreak—presumably the infected water-supply. But in the case of this 18 per cent., either because the local multiplication of the bacilli after infection was insufficient, or because of the existence of some factor of insusceptibility of the men, no symptoms of illness were produced.

Similar observations might usefully be made in other outbreaks of dysentery, or of enteric fever, where a generally operating cause like water or milk infection is suspected.

THE "INSTINCT-DISTORTION," OR "WAR NEUROSIS."

BY DONALD E. CORE, M.D. MANCH., M.R.C.P. LOND.,
HONORARY ASSISTANT PHYSICIAN, MANCHESTER ROYAL INFIRMARY; PHYSICIAN, ANCOATS HOSPITAL; CAPTAIN, R.A.M.C. T.F.

IN a paper published some little time ago[1] it was pointed out that functional nervous disorders could be divided into two groups, according as to whether they were or were not determined by environment. Hysteria, and the neurosis about to be considered, belong to the former of these two groups, both being influenced by environment, while neurasthenia or the functional nerve disorder brought about by exposure of the nerve cells to prolonged poisoning by micro-organismal products, and certain of the reflex neuroses, belong to the latter.

The group of cases now to be considered resembles the hysterias in that environment plays a dominant part in their formation, but they differ from them in two respects: (1) in hysteria the rôle of environment is indirect, whereas in these cases it is direct; (2) hysterical phenomena are based on a physiological reaction, while the group under consideration is not so based; the phenomena are pathological and subserve no useful function in the shielding of the conscious mind from unpleasantness. For all practical purposes it is a product of modern warfare; it occurs in people correctly adapted for the requirements of civilised life when such people have been, for a length of time that varies with the individual, made to live in the utterly abnormal environment produced by the war. A functional breakdown of the kind to be described is liable to happen to everyone under these conditions, the variable element being the length of time that elapses before the symptoms become manifest.

The Primary Instincts.

Our normal behaviour under conditions of civilised life is to a great extent the result of the development, inhibition, and combinations of the primary instincts among each other. McDougall describes seven such instincts:

The instinct to run away	under the emotion of	fear,	
,, ,, fight	,,	,,	anger,
,, ,, of repulsion	,,	,,	disgust,
,, ,, curiosity	,,	,,	wonder,
,, ,, self-abasement	,,	,,	subjection,
,, ,, self-assertion	,,	,,	elation,
and the parental instinct	,,	,,	tenderness.

These instincts should not be looked upon as hard-and-fast and rigidly defined from each other. Nor can we imagine that in an ideally primitive organism such instincts exist in a state of elemental purity; it is almost certain that they have evolved from a functionally undifferentiated nervous system, and that their development has been determined by environment. Generally speaking, the environment in which animal and vegetable life has developed through the ages has been the same for all forms—an environment of ceaseless stress and strain, of unending activity and competition; therefore all animal life met with on this planet manifests the presence of some or all of these instincts, their combinations and associations. But they are essentially labile, and their relative strengths depend on the minor differences in the conditions of life brought to bear upon any genus or species. But in that these instincts have developed from some undifferentiated form of nerve activity, the reactions manifested when for any cause the normal play of emotion and conation is disturbed need not be distinct and specific for each instinct involved. As a matter of fact, there is, I think, a tendency for certain of these instincts to show their "resentment" under such circumstances in a characteristic manner; but this is no more than a tendency, and need not necessarily obtain.

Now, if we consider the above seven primary instincts, we see that in that their relative strengths are the result of our customary environment, and are, in such strengths, useful for our customary environment, then, given a sudden and sufficiently radical alteration in our surroundings, the developed instincts in their relative powers may be utterly inefficient for the fresh environment. Modern civilisation tends to the safety of the individual without any very great trouble on his part, and the emotions of fear, anger, and repulsion are not, in such a state, called very frequently into action—at any rate, with any great intensity of tone. Much of the nerve force associated with these emotions is transferred to other conative activities, with results that are useful to the individual as long as he is living under the conditions of civilised life to which he is accustomed.

The Emotions in Warfare.

But under the conditions of modern warfare the emotions of fear and disgust particularly are called into frequent and violent activity. And not only is there a sudden and intense evocation of unaccustomed emotions, but the end-results and conative aspects of such emotions, so far from being given free play, are expressly forbidden, both by the idealistic conceptions acquired during childhood and early life and by vigorous punishment from fellow-men. Thus in modern warfare men are daily put into positions of imminent danger; the danger to life under certain conditions of military duty may be so great as to render death a practical certainty. In such situations men, if they are normally constituted, experience fear, and, under ideal conditions of such a position, would run away. As it is, self-respect and military discipline prevent this normal end-result, and such men proceed to fight in direct disobedience to their instinct. The helpful influence of the emotion of savage anger against their adversaries is not felt with any intensity. The disgust at the unaccustomed sights and sounds of conflict is not allowed to manifest itself in the normal way by repulsion, so that under these conditions three of the most powerful instinctive activities are distorted.

How utterly abnormal from the biological standpoint such a situation is may be inferred if we take analogous cases in the lower animal world and imagine a rabbit confronted by a hungry fox. If we further imagine the rabbit to be an idealist he might be tempted, for abstract reasons, to fight the fox, and the result would be obvious, and from the point of view of natural selection wise. Such a situation between two such animals is inconceivable, but if in place of abstract reasons the rabbit was fighting in defence of its young, then, whatever the result, the incident would be natural and the animal would probably fight more efficiently.

If we consider the above seven primary instincts we see that they are divisible into two groups, members of each reinforcing each other and antagonising those of the other group. Into one of these groups fall the emotions of fear, disgust, and self-abasement, with their associated impulses; into the other anger, self-assertion, wonder, and tenderness felt for offspring. A sense of inferiority combined with disgust reinforces the feeling of fear and renders the impulse to fly more powerful, whereas fear may be diminished by anger, a sense of superiority, and especially by the activity of the tender emotion. Unfortunately the tendency of modern warfare is to give play to the emotions of the first group without developing those of the second, and also to produce emotional tone without allowing the associated impulses to come into action. The elaborate inculcation of a hatred for the enemy and of a conviction that he is fighting in defence of his hearth and home are undoubtedly useful in lessening the destructive emotions of the first group in the case of the fighting man.

[1] THE LANCET, 1918, i., 365.

In that the occurrence of any emotion should normally be followed by the actual occurrence of its associated impulse, suppression of the appropriate conative aspect is directly harmful to the proper functioning of the nervous system, and is liable to be followed by functional disorders of this system.

In the case of the production of hysterical symptoms as opposed to those of the functional disorder we are now considering it was stated that the etiological value of the exploding shell and of the collapsing trench lay in the fact that they reinduced an emotional tone which had been at one time in the life of the patient associated with some particular incident that he had seen, or heard, or experienced. In the type of functional disorder that we are dealing with now the exploding shell and the falling trench also are important etiological factors, but they bring about their effects in a different way; they act as the "last straw on the camel's back," and simply complete the degree of fear that is necessary to make the symptoms obtrusive. In the former case these factors act as the triggers of a specially adjusted mechanism; in the latter as the final blows in the disrupting of the normal mental mechanism.

Symptomatology.

The symptomatology of the "war neurosis" differs from that of the hysterias in that it conforms to one type. In hysterical conditions of the pure or protective form there is found a cutting away from the consciousness of the patient all impulses coming from a region of the body which has been concerned in the transmission of unpleasant impressions; in the suggestion hysterias the diversity of symptoms and symptom groups is only limited by the limitations of the particular patient's powers of association, but in the war neurosis the diversity of symptoms is reduced; they conform to the various motor manifestations of fright, and are divisible into two groups.

In the first of these the fright manifestations are those associated with flight: pallor of the face with a rapidly beating heart and staring eyes, sometimes to the extent of exophthalmos; dilatation of the pupils and muscular excitability, spasm or tremor. Such symptoms in their essence are physiologically useful in that they put the animal into a state of preparedness for the obtaining of a desired objective—immediate removal from a given neighbourhood—and this is the group that is most often met with in this form of functional nerve disorder, some or all of them. When all are present the impression on an observer of utter fright is irresistible, but in actual practice all of them are not present in the majority of cases, and then the rôle of the suppressed emotion may escape attention.

In the second group the fright manifestations are those associated with the "crouching" instinct met with in certain of the lower animals, a process which keeps such animals perfectly stationary in situations of intense and imminent danger so as to avoid attracting the attention of an enemy. Here, in addition to the tachycardia, sweating, and dilatation of the pupils, there are inability to walk, or even to move the legs at all for this purpose; occasional attacks in which the patient for a short time cannot voluntarily move any part of his body; and inability to make a noise, aphonia, whispering speech, or its modification stammering.

The Element of Fear.

These somatic signs are indicative of a "choked up" conative aspect at, and leading up to, the time of their occurrence. Now, although it is true that normally the conative aspect of an instinct follows after the emotional, nevertheless it is a fact that the performance of appropriate actions tends to the production of the associated emotion. Thus, bracing the trunk muscles, clenching the hands, and setting the teeth will induce a feeling of anger; and it is to be expected that the presence of the symptoms mentioned above would reproduce the emotion of fear. This is always the case, and it is the presence of this emotion that is the deciding factor in the diagnosis of the war neurosis. These patients always at one time or another experience fear.

In the early, untreated, and acute cases the fear may be obvious and openly expressed; in addition to looking terrified, the patient is terrified, and he is terrified waking and asleep. As he improves the fear leaves him in his waking hours and is confined to his dreams, and the importance of a history of terror-dreams can hardly be overrated.

Much has been written lately on the subject of dreams and dream interpretation, and much of what has been written seems to me to be of the nature of a very elaborate structure built on very slight foundations. We do not know enough of the psychology of thought to justify detailed interpretation of dream incidents, but the emotion that is evoked by these incidents not only illuminates the general trend of the dream, but also gives important information as to what particular emotion has been excited and, if not actually suppressed, not been allowed free play during the waking hours.

The progress of a patient suffering from the war neurosis is best estimated by the intensity of the terror-dreams. In the earliest phase, when fear is felt during the waking hours, there may be a difficulty in getting to sleep at all on this account. Later, when he does sleep his rest is fragmentary, and is broken by the distress caused by his dreams. The fear-content of the dreams is so intense that it wakes him with a jerk, often with a cry; he lies for a time unable to move and sweating freely. He then drops off to sleep again, and the same behaviour is repeated throughout the night.

This phase gives way to one in which the patient on waking in the morning remembers with considerable distress the dreams that he has had, terrifying in themselves, but not sufficiently intense to wake him up. Or if he does wake up in this stage there is no free sweating.

In the third stage towards recovery the dreams do not come every night; several nights of refreshing sleep are obtained, and only now and again does he experience the dreams; in this stage he is not awakened at all by them. It is instructive, however, to notice that in this stage, if he is touched while asleep, he wakes with a start and in distress. If in the course of treatment the patient relapses the dreams revert to the early types, but not, in the majority of cases, with sufficient intensity to wake him.

As these patients improve the element of fear disappears from their waking life and in the course of time from their dreams. But in the vast majority of cases the somatic symptoms—tremor, stammering, and so forth—remain, and in such cases the final phase of the disorder has been entered, the stage of habit. The habit stage is of importance, for not only is it the stage of greatest duration, but it tends to perpetuate the condition by bringing about relapses. If while under treatment anything occurs to upset a patient's confidence in the methods of treatment he is receiving, if the conviction that he is going to recover is weakened from any cause, then his mind becomes, so to speak, sensitive to his symptoms, and in that these are the result of fear they work backwards and reproduce the emotion, as mentioned above; only the emotional intensity is rarely as intense as in the earliest phases of the condition.

These two stages of war neurosis, the emotional and the habitual, are characteristic, and their differentiation is important from the point of view of complete recovery. A patient in the first stage is ill and requires hospital treatment, whereas one in the second stage is merely inconvenienced, and very often hospital treatment is the direct opponent to complete recovery.

Another Type of Case.

In Mesopotamia and in India during the first half of 1916 quite another type, from the point of view of symptoms, of functional nervous derangement was met with. This form was characterised by evident mental dullness as far as events happening round the patient were concerned. Such patients would answer questions correctly but briefly; they took no interest in any subject under discussion and never volunteered any remarks; they were perfectly content to lie quietly and passively; they neither read nor wrote. When given any information bearing upon their interests they either took no notice at all or dismissed the subject with some indifferent remark. Their mental state was one of inertia; there were no positive signs, and to anyone who did not know anything of the antecedents of a particular patient he would seem just rather a surly and uninterested person. Yet in the course of their convalescence they proved themselves rather the reverse.

Such patients were those who had been in Mesopotamia some time, and who had experienced the distressing monotony that a prolonged residence in that country impresses upon most people. In the early days of the campaign everything there was characterised by this deadness—country, climate, occupation, and food. I cannot help thinking that the condition of intellectual inertia produced is the result of this utter absence of interest—is, in fact, the result of an

abeyance of the emotion of wonder in the instinct of curiosity. Patients in this condition recovered quickly when sent away from the country, recovery in many cases being associated with a period of irritability.

The Sex Instinct.

In view of the mass of literature, constructive and destructive, that has been published during recent years on the part played by the sex instinct in the production of functional nervous derangements, it may be advisable to discuss briefly its potency or otherwise as such a factor in the light of the evidence gained from the multitude of functional disorders that have been recently observed.

In that sexual activity is an instinct with emotional, receptive, and conative aspects, it may reasonably be supposed to be a possible source of an instinct-distortion neurosis, and in my opinion it is such a source in a limited number of cases. Its *modus operandi* is strictly analogous to that of the flight and repulsion instinct; that is, it produces a neurosis when there is an intense emotional activity with obstructed conative activity. In other words, it is not excessive sexuality nor perverted sexuality that produces the neurosis; it is compulsory abstinence from sexual activity. Given that a man with strong sexual tendencies be forced to live in an environment where he is unable to gratify them, however healthy they may be, then such a man may in the course of time manifest an instinct-distortion neurosis. I do not think that there is any need to postulate the existence of "repressed complexes" or other subtleties; a man in this position may masturbate or fall into homosexual practices, or, what is still more important, he may fear the possibility of such a happening. The end result is the same: he worries himself ceaselessly over his condition and ultimately develops mental depression. Such men frequently tend to struggle against this depression and to overcompensate in the direction of high spirits, and their neurosis takes this form—cheerfulness and high spirits with periods of intense depression—and such patients require careful watching, for they not infrequently resort to suicide.

Of course, in the case of men and women of an hysterical type the primary incident may be of a sexual nature, but this is not in any way essential, nor is it, in my opinion, at all frequent, at any rate in this country. The sex neurosis works through the medium of worry, and it is difficult, I think, for some of us to realise how intense this worry may be. Such cases may be suitably called "isolation" neuroses, for it seems probable that in addition to enforced sexual abstinence the factor of loneliness plays a part.

The sex instinct is most emphatically not of primary importance in the production of the war neurosis.

Causation.

It will thus be seen that the war neurosis as described above differs entirely in its mode of origin from hysteria. The latter condition clinically is the result of an improper suppression of a tendency that is inherent in every one of us and which is determined by our position in the scale of evolution; it is manifested as a result of an emotional activity which is normal as far as the emotion is concerned. The former is the result of an improper strain on the emotions themselves, leading to a wrongful emotional tone and to distortion of the bodily mechanism which is associated with the conative aspect proper to the emotion concerned. To use an analogy, there is all the difference between the two conditions that there is between the emptying of a reservoir by raising the sluices in the dam and by smashing the sluices or the dam itself.

The actual method by means of which emotional activity becomes manifest as somatic phenomena is an interesting problem that does not concern us here; the work of Cannon and others indicates the sympathetic nervous system and certain of the ductless glands as important connecting links. It is important, I think, to exclude from the pathology of "shell shock" (which is a term generically applied to certain hysterical and instinct-distortion phenomena, and which is about as applicable to either as "cold" or "chill" would be to all varieties of inflammation of the lungs) any lesion which gives rise to organic clinical signs. Cases in which after death hæmorrhages and compression lesions are found are better called "shell disease," after the principle that distinguishes caisson disease. The different functional disorders included at present under the name of shell shock should be sharply separated from those in which organic lesions can be diagnosed during life.

In this way, then, a shell exploding so close to a man that the violent alterations in the air-pressure bring about cerebro-spinal hæmorrhages and other disruptive effects would produce "shell disease," whereas the explosion that completes the measure of emotional stress in the manner described above, and which brings into eminence a condition that has long been incubating, produces "shell shock," so-called. In the presence of signs of organic disease shell shock should not be diagnosed, but shell disease. Of course, there are bound to be cases in which the diagnosis between the two conditions is of extreme difficulty, but from the point of view of both prognosis and treatment it is well to go on the principle of diagnosing shell shock only when a thorough examination reveals no signs of organic disease, and shell disease when such signs are present.

Diagnosis.

The diagnosis of the instinct-distortion, or war neurosis, is, as a rule, easy. In the absence of signs of organic disease it may be made in the case of any patient who shows symptoms of nerve irritability and in whom, at one time or another, the element of fear is present. In the event of such symptoms existing in a patient who shows no signs of fear, either in his waking hours or in his dreams, one of two conditions may be present—the war neurosis in the late or habit stage, in which there will be a history of terror-dreams at the beginning of the illness; or a suggestion-hysteria, in which case no such history is obtainable. Naturally, leading questions should not be asked; the patient should merely be asked if he sleeps well, or if he slept well at the time of onset of the breakdown.

It sometimes happens, though not in my experience very commonly, that an instinct-distortion neurosis and a pure hysteria exist in the same patient.[2]

I recently saw a young soldier, a private, who was under treatment for herpes zoster. The condition affected the left side of the chest, in the area of the fourth dorsal segment. While under treatment he quite casually mentioned that he had been recently suffering from what he called "attacks," after he had been in bed for a little time and when he was going off to sleep. In these attacks, which only lasted for a minute or so, he lost his sight, and all power of making a noise; he was absolutely unable to move a limb; he came to himself sweating, and, as he described it, "sick with fright."

The emotional tone of the incident, the inability to move or to make a sound were quite characteristic of the instinct-distortion neurosis, the symptoms conforming to those of the second group mentioned above, but the temporary blindness was difficult to account for on the grounds of an instinct-distortion neurosis.

Looking through some past notes of the case, however, the following entry was found: "The patient states that what worried him most when in Flanders were the horrible sights, to which, unlike most of his companions, he could never get accustomed." The amaurosis, in fact, was the result of a pure or protective hysteria, and the condition of the patient was due to the existence of the two types of functional nerve disorder.

The actual determining cause of the attacks was the sensation of his heart beating as he became drowsy; the trouble did not arise until he began trying to lie on the left, or herpetic side. The condition of the nervous system was quite slight and readily passed away; he had not been invalided for it; but in the event of his not having had herpes zoster when he did, it would be a matter of interest as to which functional derangement, the hysterical or the instinct neurosis, would have become obtrusive first. Probably the hysterical, in which case he would have been invalided for blindness.

The above case is of interest in that it indicates the lines along which an approach to the diagnosis should be made. Any particular symptom should be investigated from the standpoint of its being or not being, as the case may be, useful to the individual as a means of escape from his enemies, or of its being a derivative of such a useful manifestation. Thus, inability to move or to make a noise is obviously useful to the hare when trying to avoid attracting attention, but blindness is not, for it would militate against the final rush when the animal realised that attention had been attracted; it would prevent this realisation to a great extent. Therefore the blindness could not form part of the instinct-distortion neurosis, and further examination into the attitude of mind of the individual to his surroundings in the fighting line will ultimately bring into prominence some association with sight—either, as in the case just mentioned, distressing sights, or, if these are not complained about, some childish association in which the eyes played a part.

[2] As a general rule, in an hysterical individual the hysteria symptoms manifest themselves before the emotion neuroses have had time to develop; this is, of course, intelligible on the theory that the hysterical person develops his condition to protect his consciousness from emotional distress. The instinct-distortion neurosis may be coloured by a suggestion hysteria, but in such a case the greater includes the less, and the case should be looked upon as an instinct-distortion neurosis.

Treatment.

The treatment of the instinct-distortion neurosis is, in its essence, simpler that that of the hysterias, and more satisfactory. This, of course, follows from the fact that in the latter conditions symptoms are treated, while the underlying condition remains; the patient is hysterical to the end of his life. In the former, however, the harmony of the nervous system can be, and as a rule is, fairly easily restored, the difficulty experienced in practice being the persistence of certain symptoms as habits, and even these are more readily removed than would at first sight appear probable. In the course of time, when all ideas of the war as an imminent factor have disappeared, the more troublesome of these symptoms will be done away with owing to their very obtrusiveness, while the less troublesome will only persist as long as they do not interfere with the patient as a useful individual in the surroundings in which he works.

Treatment falls necessarily into two groups according as to whether the patient is or is not ill. These two groups correspond fairly accurately to the phases mentioned above, the active or terror phase of the illness and the habit phase.

There are two fundamentally important principles in treatment that should always be kept in mind. The first is that the patient must be removed as quickly as possible from the environment which was responsible for the condition—he ought to be taken right away from any focus of fighting; and the second is that from the very beginning he ought to have it impressed upon him that he is going to get completely cured. The removal from the combatant atmosphere is so obvious and so usual that its importance as a method of treatment as well as the light it throws on the origin of the condition is in danger of being overlooked.

When such a patient has arrived at the "ultimate base" wherein the remainder of his treatment is to be effected, if he is still in the active stage he should be kept for the most part in bed and in a ward that is quiet. It is inadvisable that he should be alone; I think that a ward with two other patients in it forms the best environment. Here he should stay until he is able to sleep without being waked up frequently by his dreams. In the early stages, when he is unable to sleep at all, I have found the best results with trional, 10 gr., with or without aspirin, and diminished gradually as the tendency to sleep improves. During this period it is well to make him realise that he has power over his legs by making him take a few steps every day in the ward, but as long as he is definitely "ill" with his condition he ought to spend most of his time in bed. He should be seen frequently by the medical officer in charge and should be constantly reassured as to his complete curability and encouraged to look upon himself as improving from day to day.

As the sleep improves and the dreams lessen in intensity he should be made to leave the ward for a short time each day and mix with the other patients, and then the more detailed treatment may be instituted. It will be found that patients manifest one, some, or all of the following disabilities: speech defects, tremors, disorders of gait, mental depression, irritability of the sympathetic nervous system

As regards *speech defects*, the principle of treatment may be summed up in the words, "careful and painstaking re-education." At the Seymour Park Military Hospital in Manchester we have been fortunate enough to obtain the assistance of the officials of the Institute for the Deaf and Dumb in the treatment of cases of disordered speech, and the results have convinced me that these patients are the most readily curable of all. Definite classes are formed, and the men are shown the position of the lips in the articulation of the vowels and their compounds. They are taught breathing exercises, are made to read aloud, and are discouraged from speaking to fellow-patients while they stammer. The result in the majority of cases is little short of marvellous, but, as in all cases of the instinct-distortion neurosis, treatment must be painstaking and to a large extent individual, and a very considerable degree of patience is required.

Similarly, in the treatment of *disorders of gait*. In the event of there being complete inability to move the legs at all, the patient should be made to sit on the edge of the bed and "feel the floor with his feet." Often enough this produces clonic spasms of the legs and the patient at first can only practise for short periods at a time, but if he is made to practise regularly and is systematically encouraged these spasms lessen, and he then begins to apply pressure to the floor with the feet. He should then be supported and made to stand, and to take a step or two; in the course of a very short time with support he will be able to get over the ground easily. The support should then be lessened, and it is well to remember that it is very much more easy to err by keeping the support, orderly, crutches, or stick, too long than not long enough. As soon as the patient can move fairly well when supported by an orderly he should be given crutches, and when he realises that he can manage these he should be made to give them up and take to a stick. The same principle is repeated with the stick; he should discard it as soon as he is able to use it with comfort. During the orderly, crutch, and stick stages he should be made to take exercises of precision over a track marked out on the floor. Two lines are painted on the floor about three feet apart, and foot-marks are indicated between them; the patient is told to walk between the lines, putting his feet on the marks. The proper use of the thigh and leg muscles should be insisted upon. These exercises may be associated with the use of a treadle machine.

Tremors also should be treated with exercises of precision. The coarse, clonic spasms of the early stages of the condition readily subside as improvement in walking is attained—and the less the patient's attention is drawn to the hands and arms in this stage the better. In the stage of the fine tremors he should be made to use his hands and arms in the way that best appeals to his interest; he should be made to construct models with a set of child's bricks or, in the later stages, with some of the "Meccano" outfits. Or he may be encouraged to manipulate chessmen or to do crochet work. The extent of useful exercises for tremors in the later stages is very nearly endless, and it requires only a little imagination on the part of the medical officer, sister, or nurse to suit a patient's requirements and, in addition, to make the exercises interesting. At the same time, these exercises should be carefully watched; any tendency on the patient's part to look upon them as a means of getting through the day apart from any therapeutic value must be checked; also, as soon as he has become proficient at one set of such exercises he should be given another and more delicate set. And when all signs of mental disturbance have disappeared and he realises that he can do useful work with his hands, then the sooner he is discharged from the hospital atmosphere into some form of civil employment the better.

An interesting symptom-group that occurs in certain of the patients suffering from this form of neurosis is *mental depression*, and often enough this only becomes obvious in the later stages of the disorder. Such depression may be due to the troublesome nature of the symptoms for which, primarily, a patient is undergoing treatment; in such a case it subsides as the symptoms improve and requires no special treatment. In other cases it is present in the absence of any obtrusive somatic symptoms, and then treatment should proceed along two lines—"therapeutic conversations" and employment. Therapeutic conversations should always be added to whatever form of treatment any patient with the instinct-distortion neurosis is receiving, but when there is well-marked mental depression they become of paramount importance. In such conversations, as far as possible, the "doctor and patient" atmosphere should be avoided, and in most cases in my experience psycho-analytic methods are not needed. The patient should be treated in a friendly manner, and in the course of time definitely asked what is troubling him. If sufficient tact has been used I find that there is usually very little difficulty in getting him to say what is on his mind; often enough, unfortunately, the cause of the depression is perfectly reasonable, and as far as medical treatment is concerned is not removable. And of all the causes domestic worries are the most potent. In other cases the depression is the result of disabling symptoms that are irremovable. In one case I saw profound depression was caused by gross nystagmus, apparently the result of hæmorrhages round the fourth ventricle and aqueduct; the case was one of shell disease. Depression caused by obtrusive symptoms is best treated by giving the patient occupation in experimental workshops; work which is not specially interfered with by his condition is chosen for him, and he is encouraged to make himself proficient in it. The more he is made to realise that he is not utterly disabled the more the depression lessens, but in some cases we have to admit that the depression is justified.

The *tachycardia* and other signs of irritability of the sympathetic nervous system are best treated by graduated exercises. It is an unfortunate fact that patients suffering in this way are extremely difficult subjects to convince that there is no organic disease of the heart; in the mind of the average patient palpitation, præcordial pain, and giddiness are incontrovertible signs of "heart disease." Such patients are best treated in hospitals specialised for heart conditions, in which the whole atmosphere of the patient is directed towards his realisation that his symptoms are in no way dangerous, and that by training they will cease to hinder his activities in after life.

Nomenclature.

In conclusion, it may be permissible perhaps to discuss the nomenclature of this condition, the instinct-distortion neurosis. The usual name, shell shock, is unfortunate, because it covers cases that are hysterical as well as those that are not, but which are the results of a strained emotional activity. But shell shock covers neither of these conditions completely; the most characteristic cases of the instinct-distortion neurosis may give no history of shell shock. On the other hand, what soldier patient that has been in the front line for any time has not been in the sphere of bursting shells? The name "shell disease" is applicable, for it is the direct disruptive effect of the explosion that produces the lesions of that condition, but shell shock, as a name applied to functional nervous breakdown in soldiers, cannot be justified.

Exposure to the sights and sounds of the modern battle-field may bring on hysteria manifestations or symptoms of the instinct-distortion neurosis. This latter name is clumsy, and "war neurosis" is too general a name to be applied to this disorder.[3] The more specific name "terror-neurosis" is perhaps a little invidious at the present time, and I would suggest calling the condition described in the foregoing pages "dysthymia" (δυς, impeded; θυμός, emotion).

We could then sum up the state of affairs as regards the factor of the exploding shell thus: The neuroses usually met with as results of the present war are hysteria and dysthymia. Neither is exclusively the result of the war, but of the two, dysthymia is the nearer approach to a specific war neurosis. In neither *need* there be a history of a bursting shell or a collapsing trench; such a history *may* be present in both. The bursting shell and the collapsing trench have no specific value in the determination of these neuroses; they possess an adjuvant value only, and this value may be obvious or masked. Only in "shell disease," where there are demonstrable organic lesions, have these factors any specific value, and the resulting condition is not functional.

[3] I have recently seen a most characteristic example of this neurosis in a woman, resulting from physical fear of being confined. The neurosis became evident shortly after marriage and became acute during pregnancy.

ON DISAPPOINTMENTS OF VACCINE THERAPY.

BY H. G. ADAMSON, M.D., F.R.C.P. LOND.,
PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL.

THE value of prophylactic vaccination has long been firmly established, but in regard to the efficacy of vaccination as a curative agent there is to-day considerable difference of opinion, and for many who have given this treatment a prolonged trial the results do not satisfy their earlier hopes and expectations.

Experience of Dermatologists.

As has often been the case with new remedies, dermatology was one of the earliest fields for the trial of curative vaccines; and there are two affections of the skin, of microbic origin and difficult to cure, in the successful treatment of which vaccine therapy at one time seemed likely to be of great assistance. These two affections are *chronic staphylococcic infections* and *lupus vulgaris*.

Experience extending over a dozen years has shown that this early promise has not been fulfilled. It is probably true to say that most dermatologists will hesitate at the present time before embarking a patient afflicted with sycosis or other chronic staphylococcal infection of the skin upon a course of vaccine treatment; he will, perhaps, as a last resort employ vaccines, but he will hesitate, since it is not possible to predict with any certainty that the patient will eventually be benefited, and his anticipation of a cure will generally be in inverse proportion to his experience of the treatment. Personally, always with an intense desire to see good results from vaccine treatment in these obstinate cases of chronic staphylococcal infection, I have been so unfortunate as to have but rarely met with them either in very numerous cases treated by myself or in my own cases treated by expert bacteriologists.

Striking cures are, indeed, reported, and it must be admitted that good results are occasionally observed with vaccine treatment in the less chronic forms of staphylococcal infection of the skin, in recent furunculosis, and in pustular acne which is not of long standing; but such results are by no means constant, and in the majority of cases there will be but temporary improvement, if really any improvement that cannot be attributed to other treatment carried out at the same time or to accidental coincidence with the natural course of events. In some cases the eruption will become worse.

And, again, it is certainly correct to say that most dermatologists will not now recommend tuberculin treatment as a likely cure for lupus vulgaris, and that many will avoid it as being fraught with danger. In my own experiences, in every case of lupus treated by tuberculin the disease has subsequently become less controllable than before the treatment was used.

Experience in Other Fields of Medicine.

If we compare the experience of dermatologists with that of others in other fields, we find much the same opinions to prevail. From a perusal of the reports of the discussions on vaccine therapy which took place at meetings of the Royal Society of Medicine in 1910 and in 1914 we gather that although this treatment may now and then appear to give dramatically successful results, it more often fails, and sometimes does harm.

Sir Thomas Horder summed up the opinion of many when he said that "the failures of vaccine treatment are more frequent than its successes."

In respect of the value of vaccine treatment in enteric fever, in gonorrhœa, and in ulcerative endocarditis, there are differences of opinion, and many observers have expressed themselves as dissatisfied with the results in these affections.

In connexion with the treatment of septic wounds of war curative vaccine therapy has proved of comparatively little value, and Colonel Sir Almroth Wright seems to admit that it takes but a secondary place compared with preventive vaccination, for he remarks to-day in regard to the treatment of wounds that—

> "Prophylactic employment of vaccines is not only from the theoretical point of view the best of all methods of employing vaccines, but it is also the method which gives in practice the maximum advantage."

And again he writes—

> "Treatment by physiological methods ..... procedures such as the opening and draining of the wound ..... is beyond all comparison the most important, and I would admit that—all loud talk notwithstanding—antiseptic treatment is at the best an ancillary method of treatment. And of course," he adds, "the same applies also to treatment by vaccines."

These statements appear to indicate a distinct recession from the opinion, which he expressed in 1909, that—

> "The principle of building up the resisting power of the system against any microbe which may have entered the body will ultimately hold its own even against the principle of warding off infection from the susceptible patient."

To-day prophylactic vaccination "is the best of all methods of employing vaccines," and "treatment by vaccines" "at the best an ancillary method," "all loud talk notwithstanding."

Consideration of Comparative Failure of Curative Vaccination.

How are we to account for this comparative failure of curative vaccination as contrasted with the striking success of prophylactic vaccination? Is it not that in prophylactic vaccination we are dealing with a less intricate problem and a proceeding which is better supported by known facts than that which confronts us when we attempt to cure an already existing infection by means of vaccines?

It is easy to see that *preventive* vaccination has a sound foundation. The study of immunity reactions has established the general principle that when an animal becomes infected by a micro-organism it is rendered, after a period of incubation, specifically supersensitised to the toxins of that micro-organism—to use the expression of Von Pirquet, a condition

of allergy or altered reactivity is produced. As a result of this allergic condition the animal is protected against a second infection. An attempt to produce a second infection gives rise to a reaction more violent than the reaction to the first infection, which has a shorter incubation period and which ends in spontaneous cure. The efficacy of prophylactic vaccination is demonstrated in the results of preventive vaccination against small-pox and against enteric fever.

But when we come to the cure of an already present infection we have altogether different conditions. The protection which has been acquired against a second infection varies in degree and in the length of time it endures in different diseases. In certain infections the reaction is such that the infected organism completely overcomes the invasion and remains henceforth protected against the disease. This occurs in small-pox and in scarlet fever, among other complaints.

In a second class the patient, although protected against a second invasion from without, yet remains infected and is liable to new infections from within—that is, to auto-inoculations. This occurs in tuberculosis and in syphilis.

In a third class the protection is apparently of but short duration and seems often to be followed by a period of increased susceptibility, so that new infections may easily take place. This is seen in streptococcal and in staphylococcal infections and in influenza, for example.

What we require to know in regard to the second and third of these classes is whether in a subject whose immunity development has been insufficient completely to overcome the infection we can by appropriate doses of vaccines so enhance the production of immune bodies—i.e., so "build up" the resisting power of the system against a microbe which has entered the body—that the defeat of the invasion is assisted or completed; and whether we can do this without danger of discrganising the mechanism of immunity and possibly lowering instead of raising the powers of resistance.

Production of Protective Bodies.

The early promise of Wright's method of curative vaccination was that we could avoid the danger of over-stimulation and its risks of fresh infection, such as we became familiar with in the early days of treatment by Koch's old tuberculin, by regulation of the dosage, and that we were able to enhance the production of protective bodies without so disturbing the mechanism of immunity as to do harm.

This method was based upon the hypothesis—

"That the blood of those who become the subject of a bacterial invasion is deficient in protective substances," and "that by an injection of corresponding bacterial vaccines the content of the blood in protective substances can in practically all cases be increased."

These protective substances were "hypothetical substances in the serum which incite phagocytosis by action on bacteria"—i.e., opsonins. It was further maintained that the measure of the production of protective substances could be gauged by the observation of the opsonic index and the appropriate doses of vaccine measured accordingly.

This hypothesis is exceedingly simple, and if it expressed the whole problem of immunity vaccine treatment would be a straightforward proceeding. But in reality it is simple because it ignores a good many facts and current ideas in regard to immunity production.

It ignores the teaching that an infected organism develops specific immune bodies as a consequence of becoming infected, for according to Wright a patient suffering from an infection, such as lupus vulgaris, has a lower "opsonic index" than a normal uninfected person—that is to say, he has less protective substances in his blood. But according to the more generally accepted view a patient with lupus vulgaris is protected against fresh infection because he has acquired protective bodies which are absent in the normal person. Although the average "opsonic index" of lupus cases has been found to be 25 per cent. below normal, yet every case of lupus gives a "cuti-reaction" to tuberculin, and thus indicates a body content of protective substances above the normal.

Again, in cases of enteric fever agglutinins are present in the blood which are absent or deficient in the normal. Yet the hypothesis of Wright supposes the blood of the enteric patient to be deficient in protective substances.

But although the hypothesis of Wright seems totally to ignore the teaching that an infected person develops protective bodies as a result of infection, it yet supposes that these bodies can be developed as a result of vaccination, an attitude which seems contradictory.

It is doubtless perfectly true that the immunity reactions may be stimulated by vaccination, but we must not lose sight of the fact that a person who has been infected is in a state of allergy or altered reactivity or hypersensitiveness towards the toxins of micro-organisms by which he is infected, so that the reaction which may result from even a minute dose of vaccine may be enormous in proportion to that which would occur from the same dose in an uninfected person, and that such an excessive reaction may be followed by a period of exhaustion of immunity or "anergy." And this seems to be the danger of the proceeding of so-called curative vaccination, that we cannot estimate the result of a vaccine in an already infected subject. The minutest dose of vaccine may set up in an infected subject an explosive reaction whose force we are quite unable to predict or control.

The Opsonic Index.

According to Sir Almroth Wright's hypothesis the proper dose of a vaccine may be estimated by the opsonic index. But this hypothesis ignores the fact that in many infections the polynuclear leucocytes or phagocytes take little, if any, part in the defence against the invading micro-organism. In tuberculosis, for example, the cellular defence is a connective-tissue-cell defence and one in which the polynuclear leucocytes appear to take no part. And when we examine the results of depending upon the opsonic index as a measure of the production of protective bodies by vaccination we find that this has proved altogether unreliable. For in 1904 1/500–1/20 mg. of new tuberculin was regarded as an "extraordinarily small dose." In 1906 Sir Almroth Wright said:—

"I now begin with a quantum of tuberculin corresponding to not more than 1/1000 milligram of T.B. powder and never advance to doses larger than 1/600 mg."

In 1910 the doses recommended were 1/20,000 mg. to 1/4000 mg. These doses were from the beginning controlled by observation of the opsonic index, and the earlier cases were reported as doing well with doses which were a very great deal larger than the doses which were afterwards advised to be used.

If we turn now to staphylococcal infections in the defence against which the polynuclear leucocytes do take an important part, and in which the opsonic index might more reasonably have been supposed to be of assistance, we find the same difference between the earlier and the later dosage. In 1903 the opsonic index told us the proper dose was from 2500–5000 million staphylococci and that the index could be controlled and cases cured by these doses; but in 1908 the dose was reduced to 100–250 millions. So that we must begin to doubt the value of this control even in cases of staphylococcal infection, and to ask, "Have we any reliable means of knowing the proper dose of a vaccine?"

Further Criticism.

Viewed again from another aspect, the rationale of vaccine treatment for chronic staphylococcal infection seems to be at fault. In staphylococcal infections of the skin the protection against a new infection varies with the severity of the primary infection. In the case of a carbuncle the patient is protected against a new infection and the lesion generally remains single. In the case of a boil the protection is frequently of short duration, for it often happens that a second or more boils appear before the first has disappeared; and cases are common in which there are repeated crops of boils over months or years, or a continuous infection of fresh hair follicles, as in *sycosis menti*. In these cases, in spite of the repeated stimulation of fresh infections, although there are intervals of improvement, yet the immunity reactions do not produce a cure; and it is difficult to say why we should expect a vaccine to accomplish that which the repeated reinfections fail to do. In practice we find this to be the case, and, at any rate in my own experience, we but rarely, if ever, succeed in curing a case of chronic staphylococcal infection by vaccines, and we are in danger of ultimately making the case worse by over-stimulation.

It has already been said that in practice the treatment of lupus by vaccines is proved to be highly dangerous. In the treatment of staphylococcal infections the danger of doing harm is perhaps less serious, but vaccine treatment of chronic staphylococcal infections of the skin is so uncertain in its results that it seems to have fallen into disuse in dermatological practice almost equally with tuberculin treatment.

As Sir Almroth Wright has put it—

"The body has the machinery for immunisation, and you can play tunes upon it if you know the laws. If you do not happen to know the laws when playing upon it, it may be quite injurious."

The uncertainty of the results, for most part the disappointing results, of vaccine treatment should perhaps make us pause and ask: Are we at present in a position to play tunes upon the machinery of immunisation by means of vaccines after the machinery has already been set in motion as the result of microbic infection?

It may be that vaccine treatment sometimes gives dramatically successful results, and we are perhaps justified in giving this treatment a trial in certain cases of infection where other treatments have failed. But the still prevalent tendency to employ vaccines indiscriminately in all sorts of complaints should be deprecated, because we are not really in a position to know when we may do good and when we may do harm by this treatment, since we have no means of estimating its effects in a person whose reactivity has been altered, perhaps profoundly altered, as the result of previous microbic infection.

The almost equally prevalent use of vaccines in diseases of non-microbic origin is perhaps of less consequence, but it is apt to delay the employment of a treatment more suited to the case and more efficient.

Reviews and Notices of Books.

The Life of Sophia Jex-Blake. By MARGARET TODD, M.D. (Graham Travers). London: Macmillan and Co., Ltd. 1918. Pp. 574. Price 18*s*.

Sophia Jex-Blake was born to be a pioneer. Whether she was born to be a doctor is, of course, another question. Her adoption of medicine as the profession in which she could carry on her struggle for the rights of women and for her own freedom seems to have been something of an accident; but she was born to struggle and to struggle through. From childhood to old age she overflowed with energy, an energy that sometimes spent itself in storms, or what she called "cataracts," and which undoubtedly caused unhappiness as well as happiness. Perhaps the unhappiness was chiefly for herself; if her intense and vehement affections did not always make her understand the people she loved, still less did they make her intelligible to them. She suffered accordingly, as those who give everything except calm, and accomplish everything except self-control, are bound to do. The tragedy began in childhood, when she was sent from one school to another, and a series of excellent, religious, affectionate, but (one fears) stupid, schoolmistresses found her unmanageable, while her effect on her delicate mother's nerves was such that for long periods it was not considered possible for her to be kept at home. The tragedy went on in youth, when she put her whole heart into a friendship with Octavia Hill, a person of such opposite temperament that the misery which followed was perhaps inevitable. It probably went on to some extent all her life, though the wider field in which she moved, the greater choice of companions, and the freedom she had won made its effects less visible. But the energy did not end in storms. The mother who had so often been laid on a bed of sickness by Sophia's childish naughtiness, became her dearest life-long friend. The loss of Octavia's friendship, though, we are told, it "cut Sophia's life in two," did not break her down. For many years she suffered intensely, but "till the close of her life the friendship on her side remained unbroken," and from it she drew fresh energy and idealism. She was always, we learn, "one of the most affectionate people that ever lived," and though it seems likely that she was also always difficult to get on with, she did a great deal to make the effort worth while.

Her career was as stormy and as fruitful as her personal relations. It began when at 18 she forced her somewhat disconcerted father to let her go to the newly-opened Queen's College, London, and to accept a post as mathematical tutor, for which he was horrified to find that she was to receive a salary. Teaching was, indeed, her chosen profession, but in America (which she visited seven years later) she fell in with Dr. Lucy Sewall, then resident physician to the New England Hospital for Women and Children, and was inspired with the wish to study medicine. She watched Dr. Sewall at work and learned a good deal from her, and when the death of her father forced her to return to England, she determined to seek for a medical education in a British university.

The story of the great struggle which resulted in the opening of the Edinburgh School of Medicine to women is told in detail in Dr. Margaret Todd's fascinating pages. Sophia Jex-Blake was the protagonist. Indeed, she began the struggle alone, but when the Medical Faculty and the Senate had sanctioned her admission to lectures the University Court rejected her claim on the grounds that special arrangements could not be made for "one lady." As soon as this was made public other women announced their intention of standing by her side, and the famous battle of the *Septem contra Edinam* began. It lasted from 1869 to 1873 and aroused such storms of passion as is difficult to imagine now. THE LANCET did not at first support the women, but in 1871 it "took fire," says Dr. Todd, quoting the following editorial passage: "Common candour must compel any unprejudiced person to admit that the fight has been pursued by the orthodox party *per fas et nefas* and that the ill-advised conduct of grave and learned seniors in the profession has offered only too plausible excuses to the heated blood of younger partisans to indulge in coarse excess." From this time on THE LANCET continued to urge the claims of honour and fairness on the party which claimed orthodoxy for its part, but which preferred every other method, from libel actions to organised riots and assaults. This brutality was met by the indomitable spirit of the girl students, and by the unstinted devotion of the male supporters of enlightenment, ranging from the majority of the Medical Faculty itself, and from such distinguished names as those of Professor Masson, Professor Lorimer, and Professor Calderwood, to the Irish students, who formed a defensive brigade to escort the girls to lectures, and no doubt greatly enjoyed the consequent opportunities for a free fight. In the midst of it all, Miss Jex-Blake disconcerted everybody by failing in her first professional examination. It was, of course, because she had been giving her whole energies to struggle instead of to study, and had thought a great deal more about her cause and those she was leading than about her personal success; it was very characteristic. She did ultimately become a successful doctor, but it is doubtful whether science was ever the first thing to her. The woman's movement and the help she could give to individuals seem to have come first in her thoughts till the end of her life. She was first and foremost a fine human being.

All her humanity and all her struggles are well set forth in Dr. Margaret Todd's admirable biography, which gives us a vivid picture of a varied and strongly-coloured life. It is to be recommended to all who are interested in the history of medical women, and to all who care for psychological drama and the struggle of character with environment. It is not only full of information, but is as absorbing as a good novel.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

THE following subscriptions and donations to the Fund have been received during the week ending August 6th:—

	£	*s*.	*d*.
Sergt. W. H. Cloud, R.A.M.C.	1	10	0
Capt. A. U. Millar, R.A.M.C.	2	10	0
Capt. Beatson Hird, R.A.M.C. (T.)	2	2	0
Dr. C. W. Branson	3	0	0
Capt. A. E. Chisholm, R.A.M.C.	0	10	0
Dr. J. W. Martin	1	1	0
Dr. F. W. Goodbody (monthly)	1	0	0
Dr. F. Wacher	2	2	0
Dr. C.	5	5	0
Roy. Coll. Surg. England	52	10	0
Mr. E. Spencer Evans (monthly)	0	10	0
Surg. Rowland Hill, R.N.	1	1	0
Mr. J. B. Wimble*	25	0	0
Dr. A. C. E. Harris	1	1	0
Mr. A. Ward*	2	2	0
Dr. Brown Kelly	5	5	0
J. G. C. Mancuniensis	3	3	0
Dr. J. Brindley-James	1	1	0
Capt. G. W. Curtis, R.A.M.C.	2	2	0
Major W. Longbottom†	1	1	0

* Per Dr. Des Vœux.

† Per Capt. G. W. Curtis.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE LANCET.

LONDON: SATURDAY, AUGUST 10, 1918.

The Medical Conditions of Industrial Manufacture.

A REPORT which has just been issued by Mr. H. M. ROBINSON, the Chief Inspector of Factories, on the work of his Department during 1917, bears evidence of the present paper scarcity. But while it lacks in bulk, and while no effort can be made to present the masses of valuable data and information to which we have been accustomed in these annual reports, nevertheless it still retains all its human interest. The documents are of the highest value in reminding us of the extent to which British industries are being carried on to-day as apart from that branch of industry which is devoted to the production of munitions of war; and this is specially valuable when there is a tendency to forget that any other industry is at present being pursued. This country is at war, and is devoting its first energies to carrying that war to a successful conclusion, but it is the very essence of our strength that simultaneously we should be able to preserve a continuity in our social and commercial life. We have endeavoured in another article this week to inculcate the same lesson, as it is brought to our notice by the impending exhibition of modern British scientific products. Mr. ROBINSON'S report marks the close of Sir ARTHUR WHITELEGGE'S long term of office as Chief Inspector of Factories. It is now more than 21 years since he was appointed, and not as a medical man but as an administrator of known capacity, in order to reorganise the Factory Department. During his period of office that Department has been entirely transformed; not merely has it increased out of all recognition in size, but its work has become more and more skilled and technical. The standard of inspection has been raised, technical experts have been added to the staff; medical inspectors, electrical inspectors, technical engineers and chemists have been appointed; and, what was regarded at the time as a startling innovation, lady inspectors of factories have been created. All these things have been done during Sir ARTHUR WHITELEGGE'S term of office, and those who have been privileged to work under him must always recall him as a great Chief Inspector.

The present report varies from peace time reports in that it presents only four subjects dealt with in detail, each written by a specialist. The record given by Mr. G. BELLHOUSE of the present position in relation to hours of work and emergency orders is one of great interest, establishing as it does the way in which hours of labour have varied during the stress of war production. He shows how the efforts made in the early days of the war have been ascertained by industry itself to be not merely injurious to the workers, but inimical to output, so that recognition, without undue legal pressure, is being given to the necessity for not merely shortening hours, but for working hours which are humanly convenient. The tendency to give up working before breakfast is marked, and it is accompanied by better time-keeping and less sickness. There can be little doubt that industry will settle down to shorter and more reasonable hours without being driven thereto by legal enactments. Miss A. M. ANDERSON'S article on the extent and effect of the substitution of women and girls in industry is of immediate importance, not merely as indicating what has been done in diluting male labour and so showing what work women can do, but as indicating what, when necessity drives, can be done to make industrial processes lighter and easier. Those who know Miss ANDERSON'S fight for the working woman in the past will find her now almost advocating the employment of women on branches of work which a few years ago she would have looked upon as entirely outside their capacity and, indeed, as work which they ought not to be allowed to attempt. To-day women in shipyards are sweeping, cleaning and doing general labour, painting, french polishing, sand-papering in joiners' shops, core-making, assisting riveters, plumbers, and electricians. They are wiring on the boats, scraping tanks and sides of ships, welding, repairing, and doing actual crane-work, and, Miss ANDERSON adds, "if one looks at the women one usually finds brighter, healthier faces in those engaged in the more exposed processes than in the parts of the works which approach more nearly to ordinary factory conditions." Mr. W. SIDNEY SMITH'S article on Doping in Aircraft Works is the story of a wonderful victory for ventilation. A few years ago it would have been thought an impossibility to change the air of an ordinary workplace 30 times an hour without causing discomfort to the workers from draughts, but Mr. SMITH and his colleagues have shown how this can be done, not merely without causing draughts, but while maintaining the necessary warmth (about 70° F.) required for the process. He points out the difficulties which he had to overcome from so-called ventilating engineers, who were so wedded to the principles of plenum ventilation that they attempted to introduce pressure fans into dope-rooms. What has been done for the ventilation in aircraft works must mark a great step forward for the more adequate ventilation of workshops as a whole.

The article upon Trinitrotoluene Poisoning, by Dr. T. M. LEGGE, which concludes the series, is an entrancing medical chapter dealing with a serious outbreak of poisoning associated with a high rate of mortality. Under the stress of war work the problem was tackled by a combination of research work and medical supervision in the factories directed from headquarters, combined with strenuous support from engineers in improving the processes and diminishing the contact with the poison. As a result, even though the numbers employed continue to increase, the poisoning has diminished until it has practically reached vanishing point. The introduction of whole-time medical

officers in the factories concerned has demonstrated the value of such medical advice on factory premises, and a great extension of this service is in contemplation in the future. In fact, Mr. ROBINSON, in his sketch of the activities of his Department, points out that in the recent large developments of industry sight is apt to be lost of the fact that the whole is a natural outcome of the activities of the Factory Department. The movement known under the term "welfare" was largely set on foot by those members of the Department who formed part of the Health of Munition Workers' Committee; and the Home Office was able to obtain legal powers for enforcing welfare accommodation which are being fruitfully used not merely for the munitions industry, but in other trades as well.

The Weapons of Science.

THE record of British scientific discovery along many lines is admitted to be without parallel—along so many, indeed, that our total contribution to developing civilisation is as yet larger than that of any nation, though the pace, which we set originally, has often been too fast for us. Equally admitted is it that the significance of the results of patient research in this country has not, in various important directions, been foreseen. In scientific initiative we have usually held the first place, but in the practical applications of our findings to the common affairs of life we have shown little aptitude, being content to allow these findings to remain as mere academic exploits whose issues could be faithfully worked out by others. What a policy! And the policy cannot be justified by any noble altruism. We have refrained from the meal which we prepared not through generosity, but because we have been too lazy, as a people, or too ill-educated in scientific affairs. It has been left for a cataclysmic war to bring this reproach home to us, and none too soon we are benefiting by our terrible lessons. It is gratifying to know that an earnest movement is now on foot to ensure that the fruits of national genius may be employed in favour of our national interests. This movement takes shape in the exhibition to be held at King's College, London, from August 12th to Sept. 7th under the ægis of the British Science Guild, when the products and appliances of scientific and industrial importance, which before the war were almost exclusively obtained from enemy countries, though the pioneer work had been accomplished by ourselves, will be displayed for public appreciation.

That our scientific workers possess something more than academic initiative, and can materialise their academic labours for the direct benefit of the community, will find remarkable illustration in the exhibits collected, but our gratification on learning this will be chastened by the remembrance of the vast opportunities which we have let slip owing to our national inability to regard scientific discovery as a weapon in practical life and not as an occurrence in a laboratory, interesting only to those immediately employed in research. The results so far achieved prove that adroit adaptation of the results of scientific research to industrial enterprise can be as boldly characteristic of the British scientist, as is his instinctive ability to wrest from nature her secrets. But until now he has awaited a stimulus, and never before was there a more striking illustration of the traditional maxim that necessity is the mother of invention. Necessity has now constrained soaring genius to answer questions of utility, with the result that our people at large can comprehend their vast debt to research, while the seekers after truth are put in good heart by a public appreciation which hitherto has never been theirs. We believe that we shall write in future not of the public neglect of science, as, regretfully, we have written in the past. On the contrary, we look forward to telling more often the story of vigorous progress by scientific means to practical ends, and to describing the opening up of vast fields of active industry, destined to secure a prominent place for this country in commercial prosperity, while contributing at the same time to world progress. Recent developments have shown that, given political and financial support, the future of scientifically directed industries is certain. How else can we interpret the successful manufactures which will be on demonstration at the forthcoming exhibition? There will be seen dyes, special glass, optical appliances, surgical, bacteriological, and pathological apparatus, certain metals—not necessarily rare but all very important—and drugs which have hitherto been entirely supplied to this country from Germany or from those associated with the German cause. To take a striking example, we have been content hitherto to rely upon Germany for our supplies of potash, when all the time we had abundant native material at our door, rich in the valuable element and only waiting for an economic process of extraction. It is now announced that from felspar, among other minerals, there can be extracted potash more than enough for our needs. In times of peace no tenets of economy or self-reliance sufficed to bring that fact home to us; but the shortage of war has braced our scientific men, and promptly there has been evolved a process for its economic extraction.

Many of the pressing economic and military problems in front of us mean, in short, the carrying into practice of principles which have been established in our laboratories. It is no exaggeration to say that next to our commanders on land and sea, the men of the moment are the chemist, the physiologist, and the engineer, in their various separate and blended capacities. Men of such qualifications should be sought out untiringly and recruited under generous conditions. The same demand comes from our great colonies—as, for example, Canada—which, as is pointed out by our Canada correspondent in another column in this issue, is enormously rich in undeveloped resources. The chemical engineer is badly wanted who can estimate whether the indications given by the test-tube can be materialised in the capacious tank or still of the works. The man familiar with the operations of the laboratory bench, as well as with general chemical principles, will recognise what an opera-

tion on massive scale demands; such a man is of prime value to this country to-day, and it is well that our politicians should have begun to perceive this truth. For much work lies ahead that ought to be done now, while the raw native materials at the disposal of the enemy give him many advantages, presenting to him a simpler problem in regard to the extraction and preparation of ultimate products. Commercial men familiar with questions of this kind, it is to be devoutly hoped, will give science that hearing which the present position claims and which hitherto has been refused. Such are the reasons why the forthcoming exhibition is of the greatest national importance, and we are glad to learn that a gratifying demonstration of what British science is able to do in regard to industrial developments is promised. Our statesmen have consistently disregarded the warnings of science in the past; they must do so no longer.

Annotations.

"Ne quid nimis."

BACTERIOLOGY OF THE "SPANISH INFLUENZA."[1]

THE pandemic of influenza has not spared any single part of Germany. The clinical course does not seem to differ from that run by the disease in this country. Relapses and fatal pneumonias are particularly noted. The clinical picture is declared to be identical with that of the last pandemic of 1889. A very striking observation has been brought forward and generally confirmed at a special meeting of the Munich Medical Union on July 9th—namely, that persons under 30 years of age mainly fall victims to the disease; this was explained by a survival immunity in the elder generation. The meeting considered all the aspects of the epidemic on the basis of the hospital and University material of Munich. Pfeiffer's bacillus has been found but exceptionally; streptococci, and occasionally pneumococci, were recovered from the sputum, organs, and also blood of the patients. Similar findings were recorded in 1889, and thus the present results were in "keeping with precedent." Pfeiffer's bacillus had not been found until 1892, although it should have been impossible to overlook it in 1889, thus it may be that it will yet turn up in due course. The editors of the *Deutsche medizinische Wochenschrift* have addressed a circular inquiry to all the leading bacteriologists in Germany requesting enlightenment as to the results of their laboratory investigations. Pfeiffer himself had reserved his final opinion as to the relationship of the pandemic with those of 1889 and 1891–92. He had not examined a sufficient number of cases at Breslau, but found his bacillus in some while failing to recover it from others, and was still investigating the causes of this discrepancy. Gruber answered from Munich very simply: "Influenza bacilli not found hitherto—investigations proceeding." Ulrich Friedemann, who is in charge of the infections wards of the Virchow Hospital of Berlin, expressed his belief that the symptomatology and complications of the epidemic correspond exactly with those described in 1889–90. He had not found the Pfeiffer's bacillus, streptococci and pneumococci being the most common agents of the complicating pneumonias. The influenza bacillus may be evading capture on account of faulty method of inquiry, yet on the other hand the possibility must not be overlooked that there may be epidemic diseases clinically resembling influenza of which the Pfeiffer's bacillus is not the agent. Uhlenhuth has so far reported from Strassburg the same contradictory results as those of Pfeiffer. Kolle reported under the date of July 18th from Frankfort his failure to detect Pfeiffer's bacilli in any of the few cases which he had thoroughly examined. In practically all cases there were found, however, large numbers of a Gram-positive coccus—often in a pure culture or in symbiosis with pneumococci. The diplococcus tended to develop involution forms and to grow in very long chains in the condensation water. He regards them as agents of a secondary infection in the "Spanish disease" which to his mind may not be identical with the pandemic influenza of 1889–1893. The finding of this pleomorph Gram-positive diplococcus is very interesting in view of the observations of Rosenow and his pupils in the United States.

A YEAR'S WORK AT A MENTAL SECTION.

Dr. R. Eager, Major, R.A.M.C., the officer in charge of the mental division of the Lord Derby War Hospital at Warrington and formerly senior assistant medical officer of the Devon County Asylum, has submitted to us a valuable analysis, appearing in full in the current number of the *Journal of Mental Science*, of the admissions and discharges in the division from June 17th, 1916, to June 16th, 1917, amounting to some 2429 of the former and 1466 of the latter. The main facts of the analysis may be summarised thus:—

The average number of admissions per month was 202 and discharges 122. It may be stated that these figures refer both to men who have served with one or other of the Expeditionary Forces and to cases occurring with the home troops, although the latter are now dealt with in other ways. The general method adopted was to admit the patient for the purpose of examination, observation, and diagnosis, and if his case was considered mental and he did not make definite improvement he was certified and sent to the county asylum to which he was chargeable. If, on the other hand, he showed signs of improvement he was retained in hospital till he was able to be discharged to the care of his friends. To take the admissions from among the home troops first. These amounted in the year selected to 258. Of these, 168 were eventually discharged to their civil occupation, 66 were certified and sent to asylums, 6 died, and 8 were sent back to home duty with the army. The main clinical groupings in the 258 were: mental deficiency, 53; delusional insanity, 43; melancholia, 37; neurasthenia, 26; dementia præcox, 24; G.P.I., 16; mania, 13; confusional insanity, 11; secondary dementia, 10; and alcoholic insanity, 9. The corresponding figures for the cases from the Expeditionary Force in France may also be quoted. These amounted in the same year to 1652, of which 536 were eventually discharged to some civil occupation, while 75 were sent to asylums, 11 died, and no less than 175 were sent to home duty with the army. Among the 1652 were 309 cases of melancholia, 242 of delusional insanity, 233 of mental deficiency, 179 of confusional insanity, 135 of mania, 127 of dementia præcox, 99 of neurasthenia, 78 of G.P.I., 63 of shell shock, 33 of mental stupor, and 19 of alcoholic insanity.

We wish to emphasise only one point out of much that is instructive—viz., that of 258 home mental cases 176 recovered and went back to work, while of 1652 expeditionary cases 711 recovered and also returned to work. These figures supply one more confirmation, if such were needed, of the contention that the opening of reception hospitals, as distinct from asylums, for the early treatment of the psychoses and psychoneuroses will materially advance matters in this field of medicine. THE LANCET has many times dealt with this subject, and has urged strenuously that the

unfortunate civilian patient should not be handicapped as compared with the military patient. The success of the military mental hospitals is proof conclusive of the immediate necessity of tackling the problem seriously for the civilian. As things stand at present, it is scarcely an exaggeration to say that if a medical officer connected with an asylum is consulted by some one who fears he has incipient mental trouble the only thing to be done is to tell him to "go away and get much worse," when a general practitioner will be able to certify that he is fit for admission to an asylum. Surely, one of the ironies of the situation is that certification is mainly in the hands of men who are not familiar with the subtleties of pathological mental states. The goal to be aimed at is that all cases should pass through a reception hospital prior to certification, and that the latter, if necessary, should be carried out in the special hospital by properly qualified men. The advantage of being able to treat mental cases in early non-certifiable stages is too obvious for the point to be laboured. It is satisfactory to record that a select committee of the Medico-Psychological Association is sitting to deal with such proposed reforms of the Lunacy Laws as will incorporate all the valuable experiences gained by the successful methods of treating military mental cases, the elaboration of which is one of the outcomes of the war that have brought good in their train.

HEMIPLEGIA DUE TO TUBERCULOUS MENINGITIS.

TUBERCULOUS meningitis in adults differs in many ways from the disease in children. Frequently it shows a tendency to be circumscribed to a point in the cortex and the symptoms suggest a focal lesion. At a meeting of the Académie de Médecine of Paris M. T. Legry reported a case in which the symptoms were so typically hemiplegic that a different disease was suggested.

A woman, aged 31 years, was admitted into the Charité Hospital on Sept. 6th, 1915. She had felt fatigued for two months and for a week had noticed at irregular intervals tingling beginning at the extremities of the left foot and hand and spreading over the whole of the left half of the body. She coughed a little, but examination of the chest was negative, and there had never been hæmoptysis. On the left side the knee-jerk was exaggerated, Babinski's sign was present, and sensibility and muscular power were diminished. In walking the left leg was dragged. Lying down the patient could not raise the left leg more than 20 cm. above the bed. Movements of the left arm were also limited. The temperature was 98·6° F. Because of the age of the patient, the clearly organic character of the hemiplegia, and the absence of other cause which might be invoked, specific hemiplegia, probably the result of arteritis, was diagnosed. Iodide injections were given and blood was taken for a Wassermann test. On the following days the symptoms persisted; there was no vomiting, stiffness of the neck, or sign of Kernig. On Sept. 16th the temperature rose to 102·2° and paresis appeared in the right lower limb. Lumbar puncture yielded fluid under very high pressure which presented abundant lymphocytosis and contained tubercle bacilli. Death occurred on Sept. 24th.

The necropsy showed a few isolated tubercles at the apices of the lungs. At the superior border of the right cerebral hemisphere was a thick granular tuberculous patch of the size of a 2-franc piece. In the longitudinal fissure it encroached on the paracentral lobule and on the external surface of the hemisphere on the ascending frontal and parietal convolutions. It was very adherent to the subjacent nervous tissue. In the rest of the pia mater were found some whitish-grey spots representing early tubercles. In this case all the symptoms, as well as the age and the absence of pulmonary signs, pointed to specific disease. Only the results of lumbar puncture enabled the diagnosis to be rectified.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Vocational Re-education of War Invalids.

INTERESTING experiments in the vocational re-education of war cripples have been carried out at Bordeaux and recently reported to the Academy of Medicine. Dr. Gourdon's observations extend over 5014 cases with loss of limb or grave and incurable injuries, of whom 73 per cent. have been able to resume their trade (with or without prosthesis) without special training; 27 per cent. required some new education or a modification of their old work. 30 per cent. only of the patients examined were disabled in the upper extremity. In each case a careful examination of physical and psychical aptitude was made, for the war cripple varies greatly in both these respects, and it is essential to place him under the surveillance of instructors and foremen who can adapt the technical methods of a craft to the degree of intelligence, energy, and skill, as well as to the age of the cripple. 62 per cent. of the patients at the Bordeaux centre were agricultural labourers, and of all cripples the worker on the land most readily resumes his former work. He is fond of it, he knows his work thoroughly, and it is work which does not demand precise movement. Thus 85 per cent. of the smallholders or farmers, and 48 per cent. of the gardeners, were able with suitable appliances to resume work at once. Cases with loss of hand or forearm have shown practically normal output of labour; with loss of arm 75–85 per cent. of the normal; with disarticulation of the shoulder 40–50 per cent. Among lower limb cripples only those with amputation through the thigh showed any considerable handicap; in this case an output of 50 per cent. of the normal. Nearly all the cripples are apt at manual work, whether sitting or standing, the diminution of output not exceeding 10 per cent. Professor Bergonié is, from his own experience, strongly in favour of re-education by agricultural work, considering it greatly superior to, and more rapid in results than, all the methods of artificial physiotherapy practised in urban hospitals, the field-work being continued all day and every day under the supervision and direction of doctors. In the Bordeaux area during one year cripples undergoing the agricultural cure have furnished 107,000 days' work on the fields.

A Preventive and Curative Serum for Gas Gangrene.

Médecin-inspecteur Vincent, professor at the Military School of Medicine of Val-de-Grâce, has announced to the Academy of Science the discovery of a serum, prepared in collaboration with M. Stödel, with which he has successfully treated gas gangrene. The action of the serum is both preventive and curative. Guinea-pigs injected with the serum after previous inoculation showed a mortality of only 4 per cent., against a rate of 80 per cent. in the non-injected. On the strength of these results M. Vincent determined to try the curative effect upon man. Thirteen patients suffering from gas gangrene, all in a serious, four in a desperate, condition, were thus treated by him, with the result that 11 recovered. These results augur well for the new method, details of which will be furnished later, as observations are being continued.

Shock and Muscular Autolysis.

In order to decide the question of the toxicity of muscular autolysis occurring at the seat of the wound, which has been regarded by some as the principal cause of the grave symptoms of traumatic shock, M. Pierre Delbet and M. Karajonopoulos have made a series of observations which seem to establish the part played by auto-intoxication. After operating upon dogs and guinea-pigs damaged tissue from the region of the wound was taken immediately after death, finely triturated with normal saline, and incubated at 37° C. The filtered extract was then injected into the peritoneum after careful sterilisation. In dogs it was found impossible to obtain a sterile extract for this purpose. With guinea-pigs and rats, especially with the latter, which live on a flesh diet resembling that of the soldiers, the authors obtained highly autolytic extracts producing in animals all the symptoms of shock a few moments after injection—acceleration of respiration, absolute inertia, and abolition of reflexes, then gradual cessation of respiration and death in coma. They conclude

that the toxic action of muscular autolysis in shock is a very definite factor to reckon with, and that in cases of clinical shock it is essential to proceed as soon as possible to resection of the damaged tissues, or even to amputation of the limb, and that to delay intervention until the patient has recovered from shock is fatal.

August 1st.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Scientific and Industrial Council of Canada.

Professor A. B. Macallum, now chairman of the Scientific and Industrial Research Council of Canada, to which he was appointed some months ago, has presented his first report. It is his view that research work along the lines indicated by the formation of the Council should be conducted at the Universities of McGill and Toronto. He points out that when the war closes Canada will be bearing an enormous burden—an annual budget of $300,000,000, or possibly $350,000,000, and in addition heavy taxation of all kinds. There will be keen competition in international trade; and those nations will best succeed whose industries are organised on a scientific basis. As every part of the Empire is devoting great attention to the modern aspects of industry, Canada cannot afford to lag behind. The Council proposes that there be a central institute established forthwith, with guilds in various parts of the Dominion. In the central institute it is suggested that there should be a considerable number of laboratory units, or series of rooms, provided with free light, heat, and where necessary motive power, to be available for use by the various guilds. Industries, universities, and governments concerned are urged to take active steps immediately; and as the Dominion of Canada is enormously rich in undeveloped resources, the first requirement is thoroughly trained scientific experts.

The Prescribing of Liquor in Ontario.

One physician in Toronto recently issued 1274 prescriptions for liquor in 11 days. He was summoned to the police-court on four specific charges and was fined on all four, making a total of $1200. The matter was gone into thoroughly by the Medical Council of Ontario, which was in annual session the week when the cases came to trial, and it was found that many members of the medical profession in Toronto were giving more prescriptions than the practice of medicine warranted and than the law considered necessary. The Ontario Medical Council will petition the Legislature to reduce prescriptions from one quart to eight ounces; and the Ontario License Commission, under whom the law—the Ontario Temperance Act—is administered, will hereafter require vendors under licence to report all prescriptions issued by each physician for liquor on the tenth of each month, so that a record may be kept of the total of each physician for the month.

McGill University and the Admission of Women to the Faculty of Medicine.

Under the following resolution the Corporation of McGill University, Montreal, will admit women to the study of medicine:—

"That the Faculty recommend to Corporation that women be admitted to the study of medicine provided they had taken a degree in Arts from a recognised university; or that they take the double course of B.A. and M.D., or B.Sc. and M.D., at McGill University; or that they have completed the first and second year in the Faculty of Arts at McGill University, and thus give evidence that they are sufficiently mature and otherwise qualified to take up the study of professional branches. The Faculty further recommends that, inasmuch as in certain subjects separate laboratory accommodation and equipment are highly desirable, a strong appeal be made for some addition to the available funds of the Medical Faculty."

Toronto, July 2nd.

PROFESSOR JOHNSON SYMINGTON'S RETIREMENT.—At a recent meeting of the Senate of the Queen's University, Belfast, reference was made to the services of Professor Johnson Symington, F.R.S., who had been compelled by ill-health to retire from the Chair of Anatomy, which he had occupied for 25 years. Dr. R. W. Leslie attributed the high reputation of the Belfast School of Medicine in no small degree to the thorough training in anatomy received there.

TUBERCULOSIS.

French Provision for Military Cases.

THE gift on France's Day of £75,000 by the Joint War Committee of the British Red Cross towards a hospital and a farm colony for the use of French soldiers suffering from tuberculosis, reminds us that it was the American Red Cross which made it possible to complete in March of this year the large military sanatorium at Bligny, where, under the care of Dr. L. Guinard, cases of all stages are accommodated in separate rooms. For this isolated method of treatment, hitherto only available in France for a few well-to-do patients, Dr. Guinard has coined the word "alveolisation." Each patient has his own south balcony with chaise-longue.

A Factory Sanatorium.

A special investigation committee of the Medical Research Committee issued in 1915 a report on the incidence of phthisis in relation to the boot and shoe trade, and this report contained a recommendation for the establishment of a factory sanatorium wherein employment could be found for tuberculous boot and shoe operatives under modified sanatorium conditions.

This report was communicated by the Local Government Board to the Leicestershire and Northamptonshire county councils and the Leicester and Northampton borough councils, asking them to furnish the Board with their observations in regard to the practicability of the scheme and the possibility of combined action by the authorities concerned. A joint conference has just been held at Northampton at which Dr. F. J. H. Coutts (for the L.G.B.) and Dr. T. M. Legge and Dr. E. L. Collis (for the Home Office) met representatives of the four councils.

After full discussion a committee was appointed representing the four authorities, and also the Boot and Shoe Manufacturers' Associations and the National Union of Boot and Shoe Operatives, to consider practical details. This committee has now reported—

(i.) That the scheme for a factory sanatorium is impracticable owing to the complex operations of modern boot and shoe making; (ii.) that it is undesirable for a man who has contracted phthisis in the trade to go back to the same occupation: and (iii.) that it might be possible for certain processes connected with the boot and shoe industry to be carried on in workshops attached to sanatoriums under strict medical supervision.

These views have now been endorsed by the Conference, which passed a unanimous resolution to the effect that, whilst a factory sanatorium is not practicable, nevertheless the Government should give financial support to workshops connected with existing sanatoriums.

Provision of Institutional Treatment in London and Lancashire.

In reply to a recent question in the House of Commons, Sir A. Griffith-Boscawen admitted, on behalf of the Ministry of Pensions, that there is still delay in obtaining institutional treatment for discharged men in London suffering from tuberculosis. In order to reduce this delay the period of sanatorium treatment had been shortened and discharged men were being given priority of entry over civilians. He added that he was now conferring with the London Insurance Commission and with the Local Government Board with the object of securing more adequate treatment for discharged men. In Lancashire, as revealed by the answer to a question addressed to the Local Government Board, although accommodation is deficient for civilian patients, there is at present no waiting list of military tuberculous patients.

Segregation of Advanced Cases.

The Metropolitan Standing Joint Committee decided last week to make representations to the Local Government Board and to the Metropolitan Asylums Board, urging measures for placing an institution at the disposal of local authorities for the accommodation and isolation of advanced cases of tuberculosis.

Arrangement for X Ray Examination.

Lancashire county council reports that correspondence has passed between the County Tuberculosis Committee and the Local Government Board with reference to the X ray examination of patients suffering from tuberculosis at the private rooms of the honorary radiologists attached to the Manchester Royal Infirmary and the Salford Royal

Infirmary. This course has now been approved by the Local Government Board in consequence of the difficulty of carrying out the examinations in these infirmaries at the present time, provided the fee paid does not exceed £1 11*s.* 6*d.* for a single examination, or £1 1*s.* for each patient if more than one attends for examination at any given time. The committee recommends that a sum not exceeding £100 be granted to cover the cost of such examinations during the financial year ending March 31st, 1919.

A West Sussex Sanatorium Scheme.

At the meeting of the West Sussex county council on July 26th an expenditure not exceeding £2500 was sanctioned for the provision of temporary accommodation for the treatment of tuberculosis. A definite scheme to make provision for sanatoria and hospitals for treating tuberculosis was before the council at the outbreak of the war, when it was decided not to proceed during the duration. West Sussex cases have been sent to Ockley Sanatorium, where out of 33 patients no fewer than 15 were from West Sussex. But that sanatorium being no longer available, temporary provision has to be made, and premises are being sought with grounds where huts can be erected and which may hereafter become a permanent place of treatment. It was stated at the meeting of the council that the demands for treatment were constantly increasing, and in addition to the civil patients the demand on behalf of discharged fighting men was greatly increasing.

Report on Miners' Phthisis in South Africa.

In his first annual report for the 12 months ending July 31st, 1917, to the Secretary for Mines and Industries, Pretoria (U.G. 6—'18. Cape Times Limited. Price 4*s.* 9*d.*), Dr. W. Watkins-Pitchford, chairman of the Miners' Phthisis Medical Bureau, gives the results of the first periodical examination of the working miners who presented themselves at the bureau. The figures furnish for the first time a comprehensive survey of the men affected with tuberculosis, silicosis, or both diseases simultaneously. Of the 14,625 miners examined 38 were found to be suffering from pulmonary tuberculosis uncomplicated by the presence of silicosis, a rate of 259 per 100,000. 738 men were the subjects of silicosis uncomplicated by the presence of tuberculosis, a rate of 5046 per 100,000. Of these silicotic men 58, or 7·8 per cent., had reached the secondary stage of their disease. Owing to the slight degree to which early silicosis interferes with health and working capacity the subjects of the disease in its primary stage tend to accumulate in the mines. A condition of tuberculosis-with-silicosis was discovered in 95 men, giving a prevalence-rate of 649 per 100,000. On the basis of these results it appears that, of all those who were silicotic, 11·4 per cent. were also affected with tuberculosis. Dr. Watkins-Pitchford adds that this observation should not be taken as implying that approximately this high percentage of all silicotics develop tuberculosis for the following reasons: (1) That a miner may first become tuberculous and then silicotic; and (2) tuberculosis may appear in an active form long after the man has abandoned his work on account of silicosis. Had the Bureau been empowered to obtain the compulsory removal of purely silicotic miners, the prevalence of silicosis would have exhibited a decline similar to that shown for tuberculosis. Dr. Watkins-Pitchford's remarks on factitious silicosis may be quoted:—

> Despite time-honoured rumours to the contrary, it is probable that the radiographic and other physical signs of silicosis cannot be counterfeited; an unsuccessful attempt was brought to light last year. An applicant for compensation had obtained a supply of a fine black powder, by the inhaling of which, as he had been assured, the signs of "Miners' Phthisis" would be temporarily produced. The man had inhaled this material on three nights preceding his examination, but no indications of silicosis or of any other disease could be detected. The powder consisted on analysis of carbonised vegetable matter finely ground with ferruginous clay and sand. A few experiments with this material showed that, in order to produce any abnormal X ray signs, it would need to be inhaled in so large a quantity that asphyxia would result.

The Swiss Campaign.

The handbook of 600 pages issued by the Swiss Central Commission for Combating Tuberculosis (Berne: A. Francke. Price 6 frs.) has a melancholy interest, as it was originally planned as a gift-book for the Twelfth International Tuberculosis Conference which should have been held in Berne in September, 1914. The book is useful in giving a concise picture of the measures taken in a relatively small and compact country, and is to some extent a memorial to Dr. H. Schmid, the head of the Swiss Health Bureau, who died in 1916, and who was largely responsible for the organisation of these measures. A good account of the work done by women is given by Dr. Martha Sommer, of Berne, and Mlle. E. Serment. Prophylaxis is dealt with by Dr. A. Cramer, of Geneva. A bibliography is appended of work on tuberculosis carried out or published in Switzerland.

REPORT FOR 1917 OF THE COUNTY M.O.H. AND SCHOOL M.O. OF LONDON.[1]

Dr. W. H. Hamer's report to the London County Council has been published. To everyone interested in the welfare of the metropolis we commend this masterly production as deserving of attentive study.

PART I.—PUBLIC HEALTH.

Meteorology.—The relation of rainfall to disease has for long been a subject of scientific interest, and the unexampled wetness in South-East England since the outbreak of war is doubtless partly accountable for the relatively low death-rate of London during the past three years. Is it, Dr. Hamer asks, a mere coincidence that the most violent explosions ever known to mankind have been accompanied by an excess of rain more pronounced in districts contiguous to the seat of war than in any other part of the United Kingdom? This question still awaits solution. The climatic conditions of 1917 were, on the whole, propitious, and the health of the metropolis compares favourably with that of 1916, itself a year of low mortality. The long period of cold weather in the early part of the year took its toll of the aged; but, on the other hand, the wet weather in July and August, with the consequent absence of high temperatures, was favourable to infant life, the mortality from diarrhœa being low. In the autumn also, except during the closing weeks of the year, atmospheric conditions were again favourable, the loss of life from respiratory affections and influenza being below the quarterly average. The death-rate among civilians in 1917 was 15·7 per 1000, or 1·1 above that of the preceding year. The higher death-toll of last year is accounted for mainly by the excessive prevalence of measles among children in the winter months. *Infantile mortality* was equal to 104 per 1000 births, against 89 in 1916. The rate was considerably above the average in the first quarter and again at the close of the year, the suggested cause in both cases being adverse climatic conditions.

Infectious Diseases.

Notwithstanding the exceptional circumstances of war, it is noteworthy that the prevalence of the notifiable infectious diseases was for the most part low, the chief exceptions being *diphtheria* and *cerebro-spinal fever*, both of which nevertheless showed a slight decline upon the incidence of the preceding year. The number of *scarlatinal attacks* notified in each of the last two years has been far below any previous record since 1890, the first year of compulsory notification. *Typhoid fever* among the general population remained at the low level of the preceding year, itself low in comparison with 1915. At the end of the year a group of cases among consumers of oysters was recorded. Small outbreaks of typhoid fever occurred in asylum populations drawing patients from London, and certain more extensive asylum outbreaks were reported in other parts of the country. The prevalence of intestinal affections and the raised aggregate death-rate among the insane generally seem to indicate that in this section of the population the effect of war conditions was pronounced.

Influenza: its varieties and complications.—Dr. Franklin Parsons in his report on the influenza epidemic of 1889–90 recognised three forms of influenza: (*a*) nervous, (*b*) catarrhal, (*c*) gastric. "These three forms," he wrote, "have all been observed in cases occurring together under the same roof, and are evidently mere varieties of the same disease." Ever since the establishment of civil registration the three conditions known as influenza, bronchitis, and pneumonia have shown increase from time to time, as though in response to the stimulus of an epidemic influence. In other words, the great influenza epidemic of 1847–48 and the following

[1] P. S. King and Sons, Westminster, S.W. 1. Price 1*s.*

pandemic of 1890, with the subsequent epidemic waves of recent years, have each and all been accompanied by noteworthy increases in the deaths returned as from bronchitis and pneumonia. It is remarkable that for some years past there has been apparent in London an approximation, or merging into one another, of the prevalence of illness attributed in the early months to *cerebro-spinal fever*, and later, in the summer months, to *poliomyelitis*. From an epidemiological standpoint the question hence arises as to the need of associating the prevalence of influenza not only with respiratory and gastro-intestinal illness, but also with illness in which disturbances affecting the central nervous system predominate. It has, in fact, become obvious that the present narrowed connotation of the term influenza requires enlargement. Towards the close of 1917 there was a new development which has special interest in connexion with recent observations respecting the relation of influenza to these conditions respectively. In 1916 there had been considerable outbreaks of poliomyelitis in London and in New York. Moreover, in that year, as well as in 1917, cerebro-spinal fever has prevailed here synchronously with influenza. But towards the close of 1917 a distinct change of type was manifested. Cases of illness with cerebral, as well as others with pulmonary or with gastro-intestinal, symptoms were prevalent, and it soon became manifest that a special epidemic influence was at work. At first suspicion fell upon food, "botulism" and "solanism" being invoked as the source of the trouble. But as no evidence of this was forthcoming it was agreed that most of the cerebral cases were to be regarded as polioencephalitis dependent on epidemic influence, a view which is not held universally. In Paris M. Netter has described similar cases, pointing out that like prevalences followed the influenza pandemic of 1889–90. In London the condition was described as "epidemic stupor," lethargy being a prominent symptom. During the spring of the current year polioencephalitis was present in epidemic form in South Africa and in Germany, influenza raging in Spain, and a "new disease" in Sweden.

Epidemic constitution of 1917–18.—Eminently instructive are Dr. Hamer's remarks[2] on the epidemiological relations of the various illnesses described, and it remains to be seen how the views of the epidemiologist and bacteriologist are to be reconciled. We give this paragraph of the report in his own words:—

"Just as encephalitis, febrile cerebritis, influenza, and sweats prevailed in Europe 400 years ago, and have periodically occurred since that time, so, history repeating itself, they have again recently spread widely in the old and new worlds. Thus it would appear that the events of the last few months once more strikingly illustrate the 'posting character,' the unexpected manifestations and the protean behaviour of 'influenza'; and incidentally the close connexion between polio-encephalitis, poliomyelitis, cerebro-spinal meningitis and influenza now seems to be established. ..... It may be that recent events will place a limit upon the too exacting claims of the causal organisms, and lead to some exercise of the recognised principle known as the Law of Parsimony in considering additions to the list of new diseases. The want of such recognition during the last four years has made the work of administration difficult, and during the last few months there has been quite an outbreak of ephemeral new diseases which, on inquiry, have turned out to be old foes with faces new only to those not versed in the history of epidemics."

Dysenteric disease.—A localised epidemic of severe illness associated with dysenteric symptoms was reported in Chelsea last autumn, occurring for the most part in a poor neighbourhood by the river. The disease ran a course of five or six days, and in fatal cases post-mortem examination revealed extensive ulceration and swelling of the mesenteric glands. Children and young adults were chiefly affected. Of the 28 cases reported 10 occurred in one family. No light was thrown on the origin of infection by inquiry as to food and water-supply or sanitary arrangements. But a soldier who had recently suffered from dysentery was found staying in the house of one of the families attacked, and in him the whole outbreak is believed to have originated. About the same time a similar outbreak occurred in Islington, where seven persons were attacked in two adjoining houses. A discharged soldier was found living with the family first infected. Within a fortnight of this soldier's arrival two adults contracted an acute diarrhœa of dysenteric character, and about a week later two children of the same household developed a similar condition, which proved fatal to them both. All the appearances of dysentery were revealed post mortem in each case. In the adjoining house three more cases of a like nature occurred about the same time.

[2] See also THE LANCET, 1906, i., 568; ii., 1374.

In view of the extensive epidemics of dysentery recently reported in the Central Empires and in Eastern Europe, it is important that vigilance should be exercised to guard against similar occurrences in this country through the medium of military cases. The account of a limited outbreak of bacillary dysentery occurring at an institution in the eastern counties early this year, and described by Dr. Buchanan in our columns, may be studied with advantage.

Tuberculosis.

For nearly 50 years past London phthisis mortality has, with slight exceptions, fallen from year to year; the first indication of pause in the decline was in 1914. Among the *civil population* alone there were 6908 deaths from pulmonary tuberculosis in 1917, against 6491 and 6875 in the two preceding years respectively. As the annual deaths among the *entire population* in the years 1911–14 had averaged only 6286, there has apparently been an increase in phthisis mortality in the course of the war. The hardships of wartime immediately increased the mortality of males of military age, but there has been also an increase in the female mortality during the war period. The arrest of emigration on the outbreak of hostilities may be credited with a certain influence on the death-rate as well as the retention in this country of patients who would otherwise have gone abroad and whose deaths are included in the London registers. Lack of food and disturbance of the normal dietary are factors powerfully increasing susceptibility to tuberculous infection, and in the year under notice many essential articles of dietary were either scarce or expensive. To this circumstance some share of the increased mortality was due.

The tuberculosis scheme adopted in 1914 was continued and extended in 1917. The number of cases receiving treatment in that year included 670 adults and 933 children. Treatment in 37 dispensaries is provided under the borough councils' schemes.

(To be continued.)

FOURTH ANNUAL REPORT OF THE GENERAL BOARD OF CONTROL FOR SCOTLAND.[1]

THE report has for economic reasons been compressed as far as is consistent with the requirements of the Statutes, but, in fact, nothing of importance has been omitted, and it might almost seem desirable to confine it within its present adequate proportions for all future time. The Board reports that the work of the Mental Deficiency Act has had to be drastically curtailed. No expenditure upon new buildings has been undertaken, while in view of the fact that there is not likely to be any increase in the amount of the Parliamentary grant the local authorities have refrained from placing defectives under care, as they are entitled to do by the provisions of Section 26 of the Act. It has been found possible to place a restricted number of defectives under guardianship, but unfortunately many are not fitted for this form of provision for their care. Three institutions have been transferred with their staffs to the War Office for military hospitals, and as a large number of male attendants have been called to the colours it has become necessary to obtain from the military authorities a supply of Army orderlies to take their place. The total number of orderlies thus supplied amounted to 75. The Board expresses its appreciation of the action of the War Office in this matter, but we are disappointed that the report does not furnish any explanation of this rather curious exchange.

On Jan. 1st of this year there were, exclusive of those maintained at home by their natural guardians, 18,326 insane persons. This is a decrease of 559 upon the numbers of last year, three-quarters of the decrease being of men. The Board is of opinion that "the circumstances under which this decrease has occurred are of so unusual and complicated a nature that comment could not usefully be made at the present time." Among significant factors are mentioned the withdrawing of more and more men from civil life; the favourable conditions produced by the disappearance of unemployment and by higher wages; and the increase of the old age pension, which has retarded the

[1] Edinburgh: H.M. Stationery Office. 1918. Price 3*d*. net.

admission into asylums of persons suffering from senile insanity of mild types. The total number of persons admitted to establishments during 1917 was 3137, which is 414 less than the average for the quinquenniad 1910–1914. It is satisfactory to note that whereas the average admission of voluntary patients for the 10 years 1908–1917 was 136, during 1917 it was 186. The increase is not great, but, we trust, indicates a gradually increasing confidence among the general public in the excellence of the care provided in modern institutions for the treatment of mental disorders. Of private patients 199 were discharged recovered during 1917, and of pauper patients 964. The number of private patients who died in establishments during the year was 285, which is 101 more than the average of the five years 1910–1914. The number of pauper patients who died was 1612, which is 348 above the average of the five years 1910–1914. It would be interesting to learn how far this increase of death-rate may be ascribed to the removal of old patients from long-accustomed surroundings necessitated by the transfer of some of the asylums to the military authorities.

It is reported that 400 acres have been added to the arable lands attached to the asylums. The production of edible vegetables has been further increased by utilising flower-gardens and recreation grounds. At the Glasgow Royal Asylum, ground formerly devoted to flowers has produced twelve tons of potatoes and other vegetables. The cultivation of chrysanthemums in the greenhouses has been discontinued and the space devoted to tomatoes, of which 1000 lb. were grown. Nevertheless, the procuring of adequate supplies has recently been attended with such difficulty that the Board has been compelled on various occasions to make representations to the Ministry of Food. The Board points out that from a quarter to a half of the inmates of modern asylums must be regarded as hospital cases, and that for the proper treatment of such cases a liberal and nourishing dietary is essential. The Board records its gratitude to the Ministry of Food that parts of asylums have been included within the definition of medical institutions or hospitals.

THE LANCET, VOL. I., 1918: THE INDEX.

OWING to the continued shortage in the paper-supply, the Index and Title-page to the volume of THE LANCET which was completed with the issue of June 29th have been printed separately, and copies have been supplied gratis to those subscribers who have, up to August 7th, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. Such applications should be sent in at once.

Correspondence.

"Audi alteram partem."

THE FUTURE OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—In a recent issue of your valuable paper Dr. Lauriston Shaw a little overstates the views held by "the extreme left party." It would not compel every medical man upon registration to enter the service of the State, but would give them a free choice between State service and private practice. It would, however, insist that everyone who did enter the service should devote the whole of his time to it. Again, it would not countenance the State forcing upon each member of the community such medical ministrations as it (the State) deemed necessary for the maintenance of his physical health. On the contrary, it would insist on all matters even remotely connected with the diagnosis and treatment of disease and with its prevention being left entirely in the hands of the medical profession. It is satisfactory to note that the "central party" has advanced a long way towards the "left" in its desire for some form of organised State medical service. The "extreme left," too, has, I think, come near to the central party in its recognition that in any future scheme bureaucratic control of, and interference with, medical matters must be carefully guarded against.

As pointed out by Professor Benjamin Moore and myself in your columns, the outstanding differences of opinion resolve themselves into whether the service should be whole-time or part-time, whether remuneration should be by salary or some form of capitation grant, and whether the benefits of the service should be free and open to all or confined to the poorer classes of the community. Put in another way, the "central party" would exclude a large section of the community from the benefits of the public service and would have part-time medical officers so as to enable them to compete for those excluded as private patients, and in order still further to safeguard the supposed advantages of competition it would continue and expand the present panel system amongst those eligible for the benefits of the service. The "extreme left party," on the other hand, would like to abolish competition for private gain, feeling that it has many disadvantages, and that the science of medicine at all events does not need such an artificial stimulus to progress. It would, therefore, like to see a whole-time salaried service; and, further, as the sole object of any organised medical service is to ensure a healthy nation, it would like to see its benefits extended to the whole population as the best means of securing it. It would like to see the coming service made so complete and efficient in its organisation that everyone would be only too willing to take advantage of it, and the whole profession proud to belong to it. Private practice and competition would then die a natural death.

Sir Bertrand Dawson, curiously enough, whilst seeing at any rate some of the evils of competition for patients, considers that the abolition of private practice would be gravely detrimental to both doctors and patients. Under competition, he points out, reward goes to the physically strong men with plausible tongues: too little to men with brains and a conscience. The abolition of competition for private patients evidently would not be an unmitigated evil.

Dr. Lauriston Shaw, in speaking of general practitioners and specialists, says, "competition and coöperation cannot go hand in hand." Surely this truism is of universal application, and consequently competition between specialist and specialist, and between general practitioner and general practitioner, is as fatal to effective coöperation as is competition between specialist and general practitioner. In short, competition for personal gain must kill the utility of any organised medical service. Sir Bertrand Dawson compares the provision for health with the provision for education, and yet, though for the latter purpose there is a service of whole-time salaried teachers, he will not hear of whole-time salaried medical officers for the former. In schools salaried teachers undertake the subject in which they are most proficient, and they all work together for the pupils' good. It would be just as reasonable to allow each teacher in a school to compete for pupils and fees as it would be to allow doctors

to compete for patients and fees under the roofs of the magnificent buildings which Sir Bertrand Dawson pictures as health centres in every locality. Just as teachers coöperate to secure well-educated children, so must doctors coöperate in the future to secure healthy individuals, remembering that "competition and coöperation cannot go hand-in-hand," and that any effort to promote a partnership between the State and medicine based on a compromise between competition and coöperation is bound to fail.

In conclusion, may I heartily welcome Dr. Lauriston Shaw's suggestion of a national medical council acting as a professional parliament on the lines of the Whitley Report. Such a council would, I believe, be an efficient means of safeguarding the interests both of the public and the medical profession, and would remove many of the objections to a public medical service. Its success, however, would greatly depend on the profession having a clean-cut idea of its functions and duties towards the community as a whole as represented by the State on the one hand, and on the other hand towards individuals as patients.

I am, Sir, yours faithfully,

London, W., July 22nd, 1918. CHARLES A. PARKER.

MUCOID FORMS OF PARATYPHOID BACILLI.

To the Editor of THE LANCET.

SIR,—Captain W. Fletcher's paper in your issue for July 27th calls to my mind some observations I have made when working with Congo-red as a background stain which might be of use to him or to others working on similar lines. He describes a fine stippling of the background in making films of the mucoid colonies. A definite stippling results from mixing an emulsion of mucilage of tragacanth with Congo-red and spreading a film in the usual way. The size of the granules seems to vary in proportion to the strength of the mucilage emulsion; the granules are very coarse where a thick emulsion is used.

As regards the demonstration of mucoid bacterial capsules with Congo-red, working with an organism which had the characteristics of *B. mucosus capsulatus* I used the following method with a fair degree of success. A small amount of the gelatinous growth is placed at one end of a glass slide; this is then spread along with the end of another slide, using considerable pressure and a side-to-side movement. The slide is dried in the air and lightly, and not too thickly, overspread with Congo-red solution, dried, and treated with acid alcohol in the usual way. In certain parts of the film, usually at the margins and extreme end, the microscope will show the bacilli lying each in an oval dark blue area. At the margins of the film these are often seen lying like large shadows thrown in the direction in which the film was dragged and conforming exactly in contour to the bacillus from which they were clearly derived. Apparently the capsule is a definite envelope, and this being ruptured or in some way injured the dye is able to enter, and the intact bacillus is clearly outlined inside the capsule, which latter is much more deeply stained than the surrounding background.

Such appearances were not obtained with non-mucoid growths of bacilli, but I have found them in films made from mucoid colonies of *B. coli*, such as one frequently sees on MacConkey plates.

I am, Sir, yours faithfully,

T. H. C. BENIANS.

Addington Park War Hospital, Croydon, July 30th, 1918.

MUCOID FORMS OF BACTERIA: LOUIS JENNER'S WORK.

To the Editor of THE LANCET.

SIR,—In relation to the paper by Dr. W. Fletcher on Capsulate Mucoid Forms of Paratyphoid and Dysentery Bacilli I should like to call attention to some old observations of the late Dr. Louis Jenner, the originator of Jenner's stain. When director of the clinical laboratory at St. Thomas's Hospital he was in possession of capsulated and non-capsulated strains of *B. coli* which he had isolated. The characters of these strains were constant under constant conditions but could be modified, and a capsulated strain converted into a non-capsulated and vice versa. So far as my memory serves, this change was effected by passage through animals. Jenner made the important observation that the capsulated strain was much more virulent than the non-capsulated. Whether these observations were ever published or not I am ignorant. Owing to Jenner's dislike to the publication of incomplete work and his untimely death much that was of value has been lost.

I am, Sir, yours faithfully,

St. George's Hospital, July 30th, 1918. CHAS. SLATER.

ACUTE LYMPHOCYTHÆMIA.

To the Editor of THE LANCET.

SIR,—I was interested to read of Captain J. C. Tull's case of Acute Lymphoid Leukæmia in THE LANCET of June 8th, also your annotation of June 29th on a similar case of a French soldier. Perhaps, therefore, this note of the same condition in a sailor may be of interest:—

An A.B., aged 20, was admitted to R.N. Hospital, Chatham, on Sept. 20th, 1916, as a case of tubercle. Up to six weeks previously he had been in perfect health, when the symptoms he was suffering from started gradually. These were general weakness, dyspnœa on slightest exertion, and attacks of epistaxis and hæmatemesis. On examination lymphatic glands all over body were found to be discretely enlarged and of elastic consistency, their average size being about that of a filbert. Spleen was palpable 2 inches below costal margin. There was no rash.

Blood count: Erythrocytes, 1,008,000; leucocytes, 14,200; hæmoglobin, 20 per cent.; colour index, 1; polymorphonuclear cells, 16·7 per cent.; small lymphocytes, 74·0 per cent.; other mononuclear cells, 9·3 per cent. A few normoblasts were seen, but very little alteration in size, shape, and staining characteristics of red cells was evident.

The patient died six days after admission. Post-mortem examination: Subserous hæmorrhages, fatty heart, large spleen, enlarged hæmorrhagic thoracic and abdominal lymph nodes. Slight increase in marrow of a greyish colour in sternum and tibia. Microscopically, heart, liver, and kidney showed fatty changes and leucocytic infiltration.

I was surprised to see it stated that a low leucocyte count was rare in this condition. Panton, Tidy, and Pearson state that in six out of eight cases of acute lymphatic leukamia the leucocyte count was within normal limits.[1] The above case is rather curious as it was one of three cases of leukæmia to be admitted within two months, whereas in the previous 10 years I had not seen a case in the Navy.

I am, Sir, yours faithfully,

S. F. DUDLEY,

One of H.M. Hospital Ships, July 18th, 1918. Staff Surgeon, R.N.

SKIN-GRAFTING.

To the Editor of THE LANCET.

SIR,—An article appears in THE LANCET of July 7th, 1917, on skin-grafting by Captain S. R. Douglas, Captain L. Colebrook, and Mr. A. Fleming. During 12 years' surgical practice in India I have used skin-grafts for a variety of cases, particularly burns, elephantoid tumours, chronic ulcers, &c., and I have always employed Thiersch's method, slightly modified. The results have been good in the great majority of cases, and I am not at all convinced that the operation advocated by the authors is a better one, and the special apparatus, &c., complicate an otherwise simple procedure. Skin-grafts have seldom become dislodged and most of the scars have been good. The raw surface from which the grafts have been taken heals very rapidly and I have *never* known it to go septic if dressed with gauze soaked in picric acid lotion. It may be that the authors have employed Thiersch's grafts cut too thin, for it is important that part of the dermis should be taken with the skin-grafts.

It has always been my experience that the weakest parts of the scar after skin-grafting are the skinned-over gaps between individual grafts, and in the authors' method these are multiplied. Moreover, the operation is more tedious and may not be completed at one time, and healing of the wound is therefore delayed.

Suppuration is a serious factor to consider in skin-grafting, but the destruction of grafts by tryptic ferments can generally be prevented by making small holes in the large grafts opposite the small pockets or depressions in the granulating area, and by applying suitable dressings on the lines described by the authors. In India green oiled-silk with small perforations is used as a covering, and over this

[1] Quarterly Journal of Medicine, July, 1914.

gauze is applied and kept moist by a saline lotion such as Locke's solution. The marvel has always been to me how persistently grafts adhere and grow in septic wounds when they are kept at rest and provided with moisture and drainage. I may mention here that in my experience pigmented skin-grafts of Indians are more resistant than grafts taken from the less pigmented skin of Europeans.

In such an operation as removal of elephantoid overgrowth of the scrotum the whole penis has to be skin-grafted at the end of the operation, and it would be most difficult to do this successfully by multiple small grafts. By employing Thiersch's method one large and thick graft is taken and fixed to the penis by fine sutures at corona, at base of penis and at line of junction of two edges of graft. When proper dressings are applied such a graft can be readily kept in position.

It requires a certain amount of practice to use Thiersch's razor efficiently, but with experience grafts of about $4 \times 1\frac{1}{2}$ inches can be made of almost any thickness. It is very important that the assistant should know how to keep skin of thigh taut while the graft is being taken.

Many of the devices described in the article under reference are most ingenious, but it is a question if they are necessary. Local anæsthesia by nerve-blocking and infiltration is an important advance on the method of general anæsthesia. The operation described by the authors may give good results in some cases, but it is important that the many advantages of large thick grafts should not be overlooked. In India they are constantly in use, and it was in the clinic of Lieutenant-Colonel C. R. Stevens, I.M.S., that I first saw large grafts applied in the way I have described in the operation for elephantiasis scroti.

I am, Sir, yours faithfully,

F. POWELL CONNOR,
Mesopotamia Expeditionary Force. Lieutenant-Colonel, I.M.S.

TEAM-WORK.

To the Editor of THE LANCET.

SIR,—I notice the following in your note upon the Cavendish Lecture before the West London Medico-Chirurgical Society: "We shall all endorse Sir B. Dawson's plea for the development of team-work in medical practice." If these words are intended to put the stamp of approval upon the present convulsive efforts to revolutionise the medical system of the country, I doubt whether you speak for the majority of the medical profession. By some the point may appear of minor importance. "Team-work" implies a few drivers, and the rest—cattle. What matter whether the poor dumb creatures realise or approve of their destination? Some very influential, able, and organised "leaders" are extremely busy in pushing forward grandiose schemes. The vast body of the profession is inarticulate, largely because leisure is wanting to take a practical interest in medical politics. Thus a golden opportunity presents itself for meddlesome and ambitious domination, to which two other factors contribute.

The first is the unprecedented political situation. The crisis of the war has forced upon us a makeshift constitution. We have a Government without the fullest constitutional authority, yet wielding dictatorial powers. We seem, indeed, to remember an understanding that these powers were to be used solely for war purposes, all controversial matters being banned "for the duration." But these dim memories are now dreamlike; and as we hear of vast schemes of reconstruction in every direction we wonder whether we are at last blessed with a Government of universal reformers. The second factor is the absence on service of a very large proportion of our doctors. Thus we have a unique, if ignoble, occasion for the strident grinding of the axes with which our teeth are being set on edge. Another aspect of the present reforming activity should be indicated. The zealots who are promoting these subversive changes and who are so determined to uproot the standards of individual liberty and individual effort are in very many cases men of established seniority, who will suffer least if their scheme miscarry, leaving a heritage of disaster to a younger generation.

I submit, therefore, that no steps are justifiable to revolutionise the medical profession until three conditions shall have been fulfilled: (1) Until we have a Government which can claim to be representative. Our present rulers, whether good, bad, or indifferent, represent nobody. (2) Until our colleagues have returned from the front. A nice reward it will be for their sacrifices if they come home to find everything turned upside down without having been consulted! (3) Until all members have had an opportunity of voting upon the proposals. What right have a few masterful individuals to coerce a great profession without taking account of the thousands and tens of thousands of its members who may prefer to be left to work out their own salvation?

I am, Sir, yours faithfully,

London, July 17th, 1918. E. O'CONNOR.

*** Teams do not drive; they pull, and all the medical profession must "endorse a plea" for pulling together. Such a misunderstanding of a well-known phrase spoils all the force of the subsequent rhetoric.—ED. L.

THE SERVICES.

ARMY MEDICAL SERVICE.

Col. J. Meek to be retained on Active List.

To be temporary Colonels whilst specially employed: Capt. (Brevet Major) C. H. S. Frankau, R.A.M.C., T.F.; temp. Major C. H. Miller.

ROYAL ARMY MEDICAL CORPS.

To be temporary Lieutenant-Colonels: S. L. Jones (whilst serving at the Notts Co. War Hospital), temp. Major (Hon. Lieut.-Col.) W. I. de C. Wheeler, and temp. Majors A. M. Paterson and H. W. M. Tims (whilst specially employed).

Major A. D. O'Carroll relinquishes the acting rank of Lieutenant-Colonel on reposting.

To be acting Lieutenant-Colonels whilst in command of a Medical Unit: Majors C. T. Edmunds and H. G. Sherron, and Capts. (acting Major) E. Percival and A. C. Hammond-Searle.

The undermentioned relinquish the acting rank of Major on reposting: Capt. (Brevet Major) R. W. D. Leslie, Capt. A. S. Cane, Lieut. (temp. Capt.) R. Stowers.

To be acting Majors: Temp. Capt. C. W. G. Bryan, Capts. T. H. Balfour and J. J. D. Roche, Capt. (Brevet Major) D. M. Corbett. Temp. Capts. E. G. C. Price, A. Randle, S. B. B. Campbell, H. S. Davidson, H. Emerson, P. N. Vellacott, S. F. McDonald, H. H. White, R. W. S. Christmas, D. Gillespie, W. F. Neil, Temp. Capt. J. D. Gunn, Capts. H. D. Lane, M. J. Williamson, N. V. Lothian, R. E. Barnsley, A. S. Cane, W. F. Christie; Temp. Capt. E. Burstal; Lieut. (temp. Capt.) A. Mansell; Temp. Capts. (while specially employed) H. E. Rawlence, R. O. H. Jones, C. R. Wills, J. G. Heath (whilst commanding troops on a Hospital Ship).

T. P. Greenwood to be temporary Captain whilst serving at Notts. County War Hospital.

Lieutenants (temporary Captains) to be Captains: R. P. Cormack, D. W. Beamish.

J. C. McGregor, from St. Andrews University Contingent O.T.C., to be Lieutenant.

J. W. Gill and J. T. W. Stewart (temporary Captains) relinquish their commissions on account of ill-health contracted on active service, and are granted the honorary rank of Captain.

Canadian Army Medical Corps.

Temp. Major C. Hunter to be acting Lieutenant-Colonel while specially employed.

Temporary Captains to be acting Majors while specially employed: A. Blair, H. O. Boyd.

SPECIAL RESERVE OF OFFICERS.

Capt. N. H. Linzee relinquishes his commission on account of ill-health contracted on active service, and is granted the honorary rank of Captain.

J. K. T. Mills, from St. Andrews University Contingent O.T.C., to be Lieutenant.

B. G. Derry to be Lieutenant.

TERRITORIAL FORCE.

Major R. T. Turner to be acting Lieutenant-Colonel whilst specially employed.

Major (acting Lieut.-Col.) G. A. Troup relinquishes his acting rank on ceasing to command a Field Ambulance.

Captains to be acting Majors whilst specially employed: W. B. Keith, A. Oliver.

Capt. J. A. C. Macewan is restored to the establishment.

Capt. (acting Major) W. A. Brechin relinquishes his acting rank on ceasing to be specially employed.

Capt. F. W. Squair, from T.F.R., to be Captain.

Capt. D. P. M. Farquharson to be Major.

Lieut. (Temp. Capt.) J. V. Kinloch and Lieut. K. S. Beken to be Captains.

P. R. Fincher and R. G. MacGregor to be Lieutenants.

TERRITORIAL FORCE RESERVE.

Capt. E. G. Annis, from R.A.M.C., to be Captain.

ROYAL AIR FORCE: *Medical Branch.*

J. A. Giles is granted a temporary commission as Captain.

J. D. George and G. W. J. Bousfield are granted temporary commissions as Lieutenants.

THE governing body of Birkbeck College have appointed George Senter, D.Sc. Lond., to the office of Principal, recently vacated by Dr. George Armitage-Smith. Dr. Senter, who is well known for his research and writings in chemistry, formerly held the readership in chemistry at St. Mary's Hospital Medical School.

The War.

THE CASUALTY LIST.

THE following medical officers appear among the casualties announced since our last issue :—

Killed.

Capt. J. C. T. Teggart, R.A.M.C., attached R.F.A., was educated at Glasgow University, and qualified in 1912. After holding an appointment at the Western Infirmary, Glasgow, he practised at Delny, Ross-shire.
Capt. R. Jacobs, R.A.M.C.

Died.

Major H. Betham Robinson, R.A.M.C., surgeon to St. Thomas's Hospital, the East London Hospital, and King George Hospital. An obituary notice appears on p. 189.
Capt. A. B. Foott, R.A.M.C., was educated at Queen's College, Cork, and qualified in 1914, a few days prior to the outbreak of war. After holding an appointment at the Cork Eye, Ear, and Throat Hospital he joined up.

Died of Wounds.

Major J. D. Proud, M.C. and bar, R.A.M.C., was educated at Charterhouse and at Durham University, and qualified in June, 1915, forthwith joining up. The award of the M.C. and of the bar were recorded in THE LANCET respectively of June 23rd (p. 969), and of Oct. 6th (p. 549), 1917.

Wounded.

Capt. J. C. P. Bayley, R.A.M.C., attached Manchester Regt.
Lieut.-Col. W. C. Croly, D.S.O., R.A.M.C.
Capt. R. L. Williams, D.S.O., M.C., R.A.M.C., attached S. Staff. Regt.
Major G. B. Holroyde, R.A.M.C.
Capt. W. St. C. Maclure, R.A.M.C., attached R.E.
Capt. P. Ardagh, New Zealand M.C., attached Infantry.

Missing.

Lieut. J. R. McGregor, R.A.M.C.

Previously reported Missing, now reported Prisoners in German Hands.

Capt. T. Blackwood, R.A.M.C., attached R.F.A.
Lieut. F. W. M. Lamb, R.A.M.C.
Lieut. F. B. O'Dowd, R.A.M.C., attached West Yorks Regt.
Capt. R. W. Pearson, M.C., R.A.M.C., attd. Durham L.I.
Capt. A. B. Simpson, R.A.M.C.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported :—

Lieut. D. Moir, M.C., Cameron Highlanders, attached K.A.R., died of wounds, younger son of Lieut.-Col. J. M. Moir, R.A.M.C., of Inverness.
Major J. D. Proud, M.C. and bar, R.A.M.C., died of wounds, only son of Dr. F. Proud, medical officer of health for Maryport, Cumberland.
Lieut. C. E. W. Brewer, R.N., killed at sea, youngest son of the late Dr. R. E. W. Brewer, of Newport, Mon.

THE HONOURS LIST.

The following awards to medical officers are in continuation of those published in THE LANCET of August 3rd :—

The Military Cross.

Temp. Capt. EDWARD ARTHUR ALDRIDGE.—For conspicuous gallantry and devotion to duty at the dressing station, remaining until the enemy were upon him, and having cleared his aid-post, working his way back, collecting the wounded and attending to them under heavy shell fire. His courage and self-sacrifice set a splendid example, and were worthy of the highest praise.

Temp. Capt. WILLIAM BRODIE GURNEY ANGUS.—For conspicuous gallantry and devotion to duty during recent operations. He was the means of saving the lives of many officers and men, especially on one occasion when the brigade suffered severe casualties from shell fire. He was untiring in carrying out his duties and removing the wounded to a place of safety.

Capt. JOHN WEBSTER ARCHIBALD.—For conspicuous gallantry and devotion to duty during recent operations. The battery position of the brigade was subjected to an intense bombardment in connexion with the enemy attack, and although shell fire round his own headquarters was severe, he visited all the battery positions by himself, instead of having the casualties brought to him. His complete disregard for personal safety in order to save the wounded being brought through the enemy barrage undoubtedly resulted in the saving of life and of many casualties. His courage and cheerfulness under a heavy and continuous strain was of the greatest value, and a fine example to all.

Capt. (acting Major) CHARLES PHILIP BRENTNALL.—For conspicuous gallantry and devotion to duty during two days at an advanced collecting post under conditions of great danger. Although heavily shelled he succeeded in keeping his post clear and getting away all the wounded. The collection and evacuation of wounded was rendered particularly difficult owing to the fact that the troops were executing a withdrawal.

Capt. CHARLES HERBERT BUDD.—For conspicuous gallantry and devotion to duty in attending to wounded under fire. Under heavy shelling he went forward and dressed wounded, and dressed one man under full observation of the enemy.

Temp. Capt. GEORGE MILNE CAMERON.—For conspicuous gallantry and devotion to duty when in charge of bearers. He worked incessantly for 12 hours collecting and evacuating the wounded under heavy shell and machine-gun fire. Many cases were successfully got away, which, but for his determination and absolute disregard of danger, would have fallen into the hands of the enemy.

Capt. DAVID CAMPBELL.—For conspicuous gallantry and devotion to duty, when on two occasions he was the only M.O. left with the brigade. He organised regimental aid-posts and established lines of evacuation, and during a long exposure to shell and machine-gun fire set an inspiring example to all.

Temp. Capt. DUGALD STEWART CAMPBELL.—For conspicuous gallantry and devotion to duty. He worked without rest, and when it was necessary to retire successfully brought away all the wounded, in spite of the district being subjected to a heavy gas bombardment. He was undoubtedly the cause of saving the lives of many wounded.

Temp. Capt. THOMAS HAY CAMPBELL.—For conspicuous gallantry and devotion to duty. When under heavy shell and machine-gun fire he organised a forward aid-post and evacuated over 500 wounded. No wounded man was allowed to pass without personal attention, in spite of the difficulties of doing so in an exposed position.

Capt. LOUIS ABEL CELESTIN.—For conspicuous gallantry and devotion to duty. He remained with a party which was covering the retirement, and attended to the wounded under heavy rifle and machine-gun fire. Later he dressed a medical officer's wounds, and carried him single-handed for a distance of over half a mile through heavy fire when the officer he was carrying died of wounds.

Temp. Capt. RICHARD COLLIER COATSWORTH.—For conspicuous gallantry and devotion to duty during an enemy attack. He early led his regimental stretcher-bearers through very heavy shell fire to remove all wounded that could be found. He organised the removal of wounded, and by his perpetual cheerfulness and coolness set a fine example to his men, and effected the successful evacuation of many wounded.

Temp. Capt. ALAN GIBB COOK.—For conspicuous gallantry and devotion to duty while clearing wounded under heavy machine-gun and shell fire during an enemy attack. When the officer in charge of the bearers became a casualty he carried on the evacuation of the wounded, though badly gassed himself. He frequently led squads to the front line in search of wounded and showed great disregard of danger.

Temp. Capt. WILLIAM FRANCIS CORNWALL.—For conspicuous gallantry and devotion to duty. When the enemy carried out a heavy bombardment with large calibre shells and gas he established on his own initiative a dressing station and continued to deal with cases of various units for five hours, during which time the shelling was intense. To evacuate the wounded he organised stretcher parties of prisoners, no other means being at the time available.

Temp. Capt. JAMES ROBERT CRAIG.—For conspicuous gallantry and devotion to duty. He kept in touch with the retiring troops, evacuating the wounded without relief for eight days and nights. While the advanced dressing station was under heavy fire and all the other officers had been either killed or wounded he continued to carry on his work.

Temp. Lieut. GWILYM CHARLES MONTAGUE DAVIES.—For conspicuous gallantry and devotion to duty. When a neighbouring village was being heavily shelled, he went there to see if he could help. Finding that the field ambulance had withdrawn, he re-opened the dressing station and remained there for hours, managing to evacuate a large number of wounded.

Temp. Capt. LLYWELYN AP IVAN DAVIES.—For conspicuous gallantry and devotion to duty when, all the R.A.M.C. in an area having been taken by the enemy, he was sent up to establish a system of evacuation. In spite of heavy shelling he kept his cars and bearers working for 24 hours, only retiring when the infantry passed him, and by so doing prevented many of the wounded from falling into the hands of the enemy.

Temp. Capt. EDWARD FORBES.—For conspicuous gallantry and devotion to duty. While the battalion was preparing to march off 3 officers and 13 men were wounded; this officer attended to them all under heavy fire. Later he was wounded while attending to his duties.

Temp. Capt. (acting Major) CHARLES COLDER FORSYTH.—For conspicuous gallantry and devotion to duty. Hearing that help was urgently required at a certain point, he organised stretcher-bearers to clear away the wounded, of which there were over 200. He remained in the area, which was heavily shelled, during the whole afternoon and until all the wounded had been evacuated. His spendid courage and initiative in organising this evacuation undoubtedly saved the lives of many of the wounded, who would otherwise have perished.

Capt. CHARLES WAINWRIGHT FORT.—For conspicuous gallantry and devotion to duty during several days when acting as bearer officer. The conditions under which the wounded had to be collected and evacuated were particularly difficult, owing to the fact that the troops were executing a withdrawal. By his total disregard of danger and initiative in bringing forward his bearers, often under heavy shell fire, he succeeded in clearing large numbers of the wounded.

Capt. FREDERICK GAMM, Spec. Res.—For conspicuous gallantry and devotion to duty for several days when in charge of an advanced dressing station, and until it was almost surrounded by the enemy. During this time, although under a continuous and heavy bombardment, he continued to dress casualties and organise stretcher squads, which he took out to search for wounded. By his courageous action many wounded were collected and evacuated, and his splendid example was a fine stimulus to all.

Temp. Capt. DAVID GILLESPIE.—For conspicuous gallantry and devotion to duty. During recent operations he did most useful work in tending wounded and arranging for their removal under fire. The work was often done under heavy machine-gun fire at medium range. His coolness and fine example greatly contributed to successful evacuation being carried out.

Temp. Capt. MORLEY EDWARD GORMAN.—For conspicuous gallantry and devotion to duty in carrying on his work when the dressing station was destroyed by shell fire and in visiting his posts and superintending the evacuation of the wounded under heavy shell fire. Throughout the operations he displayed the utmost coolness and contempt of danger; his cheery optimism and energetic personal example inspired confidence in all.

Temp. Capt. (acting Major) HOWARD BOYD GRAHAM, D.S.O.—For conspicuous gallantry and devotion to duty while in charge of over 300 bearers, always under heavy shell fire and often under machine-gun fire at close range. It was due to his judgment that the wounded were evacuated with a minimum possible loss in personnel. On one occasion, being cut off by the enemy, he led his party to safety by a wide detour. When his dressing station was heavily shelled, with the infliction of heavy casualties, he organised the rescue work, rallied the shaken bearers, selected the line of evacuation, and, with the aid of another officer, evacuated 54 casualties to a place of safety. His conduct through this fiery ordeal was magnificent.

Temp. Capt. EDWARD WILLIAM DACRE HARDY.—For conspicuous gallantry and devotion to duty. His dressing station was situated at cross roads, the only place available, and during a whole day was obviously a target for exceptionally intense bombardment. He displayed the greatest courage and supreme contempt of danger, remaining at his post and dressing wounded the entire day while everybody else was dug in.

Temp. Capt. GEORGE FRANCIS PALMER HEATHCOTE.—For conspicuous gallantry and devotion to duty throughout many days of active operations. He was absolutely tireless in his work of rescuing and caring for the wounded, and freely exposed himself to heavy rifle and machine-gun fire in carrying out his duties. By his splendid courage and energy throughout the whole operations he was instrumental in getting away most of the wounded.

Temp. Lieut. ROBERT JOHN HELSBY.—For conspicuous gallantry and devotion to duty when, the battery area being heavily shelled, he dressed the wounded with complete disregard of personal safety, and in spite of being blown up in a house and badly shaken.

Temp. Capt. FRANCIS HENDERSON.—For conspicuous gallantry and devotion to duty. Throughout ten days' fighting this officer set a splendid example. On one day for 12 consecutive hours he was engaged in leading squads of bearers to and from the regimental aid-posts. He frequently dressed men in the open when their condition needed it. He brought a wounded officer back in a car, several times stopping it under heavy fire to make the officer more comfortable.

Capt. (acting Major) HOWARD HENRY.—For conspicuous gallantry and devotion to duty during several days when acting as bearer officer. The conditions under which the wounded had to be collected and evacuated were particularly difficult, owing to the fact that the troops were executing a withdrawal. By his total disregard of personal danger and coolness, he set a brilliant example to the bearers under his command, and undoubtedly was the means of saving many lives.

Capt. ROBERT ALEXANDER HEPPLE, Spec. Res.—For conspicuous gallantry and devotion to duty. The advanced dressing station was hit by three shells simultaneously, when the building was demolished and several men killed or wounded. He at once set to work to recover the wounded from under the débris, and did not leave till all had been cleared, in spite of the continued intense shelling of the vicinity.

Temp. Capt. STEWART HODGSON.—For conspicuous gallantry and devotion to duty during recent operations. For a whole day, often under direct rifle and machine-gun fire, he attended the wounded and directed their evacuation. Although wounded he continued his duties with exceptional coolness and skill, until the advancing enemy compelled withdrawal.

Temp. Capt. HUGH LLEWELLYN GLYN HUGHES, D.S.O.—For conspicuous gallantry and devotion to duty. He worked day and night in the open, in spite of the heaviest shell and machine-gun fire, tending the wounded and helping them back to safety, with a spirit of cheerfulness and self-sacrifice rarely seen. After being wounded he still continued to perform his duties, until the wound necessitated his evacuation.

Temp. Capt. THOMAS WILLIAM JACKSON.—For conspicuous gallantry and devotion to duty during an enemy attack. He was with two other medical officers in a dressing station when the troops in front fell back. The dressing station was full of wounded, and this officer continued, with the two others, to tend the wounded, despite the close proximity of the enemy, till, thanks to a counter-attack by our troops, every case was cleared. This was a fine act of courage and devotion to duty.

Temp. Capt. GEORGE WILLIAM BLOMFIELD JAMES.—For conspicuous gallantry and devotion to duty throughout a retirement in remaining behind with the rearguard, dressing and evacuating wounded under very heavy fire, until his medical stores were exhausted and he was in danger of being cut off. It was due to his tireless energy that so few wounded fell into the hands of the enemy. His resource and cheerfulness throughout were a real encouragement to all.

Capt. ARTHUR MORRELL JOHNSON.—For conspicuous gallantry and devotion to duty in tending and evacuating the wounded in the front line and under continual fire. When the order to withdraw was issued he remained till the last, and it was entirely due to his courage and energy that all the wounded were cleared.

Temp. Capt. FRANCIS ESMOND KEANE.—For conspicuous gallantry and devotion to duty. Throughout the operations he displayed the greatest courage and grit, working unceasingly without sleep, establishing aid-posts, and evacuating wounded under heavy shell and machine-gun fire. His services to the battalion were most invaluable.

Temp. Capt. RICHARD KENEFICK.—For conspicuous gallantry and devotion to duty. While the regiment was consolidating its position, he attended to the wounded quite in the open and under very heavy fire, and arranged for their evacuation. He undoubtedly saved many lives which would otherwise have been lost. He was wounded in the foot, but did not relax his energy, and continued to attend to all the wounded in the vicinity.

Capt. JOSEPH ILLINGWORTH LAWSON, Spec. Res.—For conspicuous gallantry and devotion to duty in bringing in wounded under heavy shell fire, with no one between him and the enemy, thereby saving them from being made prisoners.

Temp. Capt. GEORGE AUSTEN LILLY.—For conspicuous gallantry and devotion to duty. In order to attend the wounded he frequently crossed an exposed piece of ground 300 yards in length. Later, when the horses had to be moved owing to heavy shelling, he rescued a badly wounded man, carrying him to safety.

Capt. HENRY GUY LUDOLF.—For conspicuous gallantry and devotion to duty. For six days he worked under continuous fire, and during the last two days was the only doctor on the spot attending to the wounded of five different battalions. He was himself suffering from a severe attack of neuritis, but stuck to his work till assistance came. During these six days his personal heroism and abnegation of self were beyond all praise, and owing to his gallant conduct the lives of many were saved.

Capt. JOHN ALEXANDER MACKENZIE, Spec. Res.—For conspicuous gallantry and devotion to duty at an advanced dressing station, under heavy shell fire, during an enemy attack. He persisted in his work, and successfully evacuated all the wounded before withdrawing his personnel. At another advanced dressing station later he stuck to his duty for 72 hours without rest.

Capt. KENNETH AHTHUR McLEAN, Australian A.M.C.—For conspicuous gallantry and devotion to duty during a heavy enemy attack. Under heavy fire he personally conducted bearer squads, organised the forward work of evacuation, and exerted himself to the utmost in saving wounded. His fine example served to keep the men under him working at high pressure, and ensured the complete evacuation of the positions.

Temp. Capt. ALAN COWAN MANN.—For conspicuous gallantry and devotion to duty. Throughout eight days' operations this officer did fine work in tending and clearing the wounded. On one occasion, when the line fell back, he remained with the wounded and succeeded in clearing all that could be found before he withdrew. The splendid work done by the stretcher-bearers was due to this officer's organisation and leading.

Temp. Capt. HARRY GODFREY MASSY-MILES.—For conspicuous gallantry and devotion during several days of severe fighting, when he kept in close touch with the battalion, working unceasingly, without rest, during the whole period, dressing the wounded, including the French. He showed great initiative in establishing forward R.A.P.'s, reconnoitring their sites beforehand under heavy hostile shell fire, thus greatly assisting the rapid evacuation of casualties. His courage and cheerfulness throughout a period of great strain were beyond praise.

Temp. Capt. WILLIAM GRAEME DENROCHE McCALL.—For conspicuous gallantry and devotion to duty when at a forward collecting post. During an afternoon large numbers of wounded had to be dealt with, and the approaches to the station were subjected to intense shell and machine-gun fire. He maintained the position for many hours, dressing and evacuating all wounded, though later he was in imminent danger of being surrounded. When the post was quite untenable he successfully withdrew all personnel and stores. His gallantry under conditions of extreme danger saved many lives.

Temp. Capt. ROGER McGRATH.—For conspicuous gallantry and devotion to duty when in charge of the bearers of his field ambulance. During the enemy's advance, and while exposed to heavy shell and machine-gun fire, he organised his bearers and evacuated many wounded, who otherwise would have been captured. He set a fine example of energy and courage.

Temp. Capt. ALEXANDER CHURCH BRODIE McMURTRIE.—For conspicuous gallantry and devotion to duty. On several occasions he brought in wounded himself under shell fire, and by his disregard of danger set a fine example to those under him. Owing to his arrangements and untiring efforts many lives were saved.

Capt. HAMILTON STEPHEN MOORE, Spec. Res.—For conspicuous gallantry and devotion to duty in constantly leading stretcher parties through intense shell and machine-gun fire, in order to evacuate the wounded. On one occasion the whole party except himself became casualties. He dressed his men in the open, and invariably stayed till all had been got away. His cool and determined gallantry was a great inspiration to all the men working under him, and his efforts saved many wounded from being captured.

Capt. FREDERICK CECIL NICHOLS.—For conspicuous gallantry and devotion to duty. When the front line was forced back he maintained his dressing station in the newly-formed front line until he had attended to every case, in spite of a heavy bombardment. Throughout the four days' fighting he displayed untiring energy and great personal courage.

Temp. Capt. ALGER ROY ORAM.—For conspicuous gallantry and devotion to duty. In recent operations this officer, under very heavy shell fire, continued to attend to the wounded and evacuate cases under the most adverse circumstances. On several occasions, by his fine example and personal courage, he saved many wounded who otherwise would have fallen into the enemy's hands.

Temp. Capt. JOHN LINDESAY PEARCH.—For conspicuous gallantry and devotion to duty while in charge of a bearer post. He repeatedly led squads of bearers to parts of the line where wounded were collected, and it was due to his fine example that so many wounded were saved during a period when communication with the front was extremely difficult. He showed courage under shell fire and was indefatigable in his duties.

Capt. ALLAN CAMPBELL PEARSON.—For conspicuous gallantry and devotion to duty when acting as second in command of a casualty clearing station. On several occasions and on different days he superintended the evacuation of wounded under heavy shell fire, and also, with the greatest courage and ability, supervised the salving of equipment during bombing and machine-gun fire from hostile aircraft.

Temp. Lieut. ROLAND WILFRED PEARSON.—For conspicuous gallantry and devotion to duty in the performance of his duties during lengthy operations. On one occasion two direct hits were obtained on his post, and a patient, who was being dressed, was killed. On another day he followed the battalion in a counter-attack, and rendered the most magnificent services to the wounded, under heavy machine-gun fire. By his courage, fine example, and great devotion he has at all times inspired his stretcher-bearers, and it was mainly due to him that so many of the wounded were got away by the bearers.

Temp. Capt. JAMES POTTER.—For conspicuous gallantry and devotion during lengthy operations, when he continuously attended the wounded under heavy shell, machine-gun, and rifle fire, maintaining his regimental aid-post until the enemy had nearly reached it. His splendid example of courage and devotion to duty were beyond praise.

Capt. (acting Major) WILLIAM JAMES PURVES.—For conspicuous gallantry and devotion to duty at a main dressing station, when by his courage, untiring energy, and grasp of the situation over 1000 wounded were passed through the station without a hitch, and when, owing to continuous shelling, he had to retire all cases were got safely away. This was especially difficult, as the troops were executing a withdrawal.

Capt. JOHN WOOTTON RAMMELL.—For conspicuous gallantry and devotion to duty in dressing the wounded and carrying out his duties under heavy rifle and machine-gun fire. Owing to his ceaseless endeavour and skill all the wounded were evacuated. All ranks speak with admiration of his courage and good work.

Temp. Capt. JOHN KING RENNIE.—For conspicuous gallantry and devotion to duty when, an advanced dressing station having retired, he organised another in a village, which he only left when the enemy entered it, working all the time under a heavy fire. Subsequently he again organised the evacuation of the wounded under difficult conditions, and saved many from falling into the hands of the enemy.

Capt. HENRY WHITTERON ROBINSON.—For conspicuous gallantry and devotion to duty. In spite of continuous shell fire, during which his aid-post sustained two direct hits, this officer worked without ceasing, giving unremitting attention to the wounded and organising bearer squads.

Capt. PETER JOHN RYAN.—For conspicuous gallantry and devotion to duty during lengthy operations in charge of bearers and advanced dressing stations. He organised the whole forward work, and it was due to his individual efforts and energy that so large a number of casualties were prevented from falling into hostile hands. He worked continuously throughout the whole retreat, and his success was such that no wounded man fell into the enemy's hands after once having been put under the care of the field ambulance bearers. His work was carried out under extremely difficult conditions, and often under heavy shell fire. His devotion to duty was quite beyond praise.

Temp. Capt. CUTHBERT SCALES.—For conspicuous gallantry and devotion to duty when in charge of stretcher-bearers. He collected and evacuated many wounded under heavy fire, and remained at his post until forced by the advance of the enemy to withdraw his collecting post further back. There he continued collecting and evacuating as long as possible, showing a fine example to his men.

Capt. HUBERT SHIELD.—For conspicuous gallantry and devotion to duty at advanced dressing stations. Under heavy fire, he managed to save all wounded from falling into the enemy's hands, and remained doing his duty till his stations were cleared. In one dressing station, which he alone ran for 16 hours, he dressed and evacuated over 300 men.

Capt. WILLIAM SMITH, South African M.C.—For conspicuous gallantry and devotion to duty during active operations. He displayed great courage in carrying on his duties after being blown up by a shell, which wounded him and killed two of his orderlies, and he remained at duty until his battalion was relieved.

Capt. THOMAS COPELAND STOREY, Spec. Res.—For conspicuous allantr y and devotion to duty. After the withdrawal from a wood, it was discovered that some of the wounded had been left behind. He went forward and spent an hour and a half in front of the line, searching the wood, and brought them all back, in spite of considerable hostile fire. Otherwise they would undoubtedly have fallen into the hands of the enemy.

Temp. Capt. RAYMOND BREWITT TAYLOR.—For conspicuous gallantry and devotion to duty. He searched for a missing stretcher-bearer for two hours under heavy shell fire, at last finding him in a shell-hole and assisting to carry him back. Throughout nine days' fighting he was constantly going forward, under fire, searching for and bringing in wounded.

Capt. WILLIAM WALKER, Spec. Res.—For conspicuous gallantry and devotion to duty. He proceeded to a village under heavy fire and succeeded in attending and evacuating several wounded. He only desisted when the enemy entered the village. Later, he succeeded in releasing a party of stretcher-bearers who had been cut off. Throughout the operations he has shown the utmost energy and courage.

Capt. CHARLES ERIC WATSON, Australian A.M.C.—For conspicuous gallantry and devotion to duty. Under very heavy artillery fire he continued to dress the wounded for two hours and a half. Though many of the bearers were killed and wounded, he stayed with the stretcher cases, and it was owing to his fine courage and energy that many of the wounded were saved.

Capt. HARRY ERNEST BANTRY WHITE, Spec. Res.—For conspicuous gallantry and devotion to duty during recent operations. He was medical officer attached to the battalion, and for eight days he worked continuously without rest and often without food, generally under heavy fire, attending to the wounded. His efforts were tireless, and his courage and devotion to duty were the means of saving many lives.

Temp. Capt. DAVID ROBERTS WILLIAMS.—For conspicuous gallantry and devotion to duty while in charge of bearers in evacuating wounded. On one occasion, going back and searching for wounded when, in spite of darkness, barbed wire, and torn-up ground, he brought away two men from an abandoned aid-post, carrying one on his back. On another occasion it was largely due to his determination and grit that a camp which was being heavily shelled was evacuated of all wounded, when he remained till the last and saw that all was clear.

Temp. Capt. CHARLES EDGAR WILSON.*—For conspicuous gallantry and devotion to duty when, during a rearguard action, he worked untiringly in the interests of the wounded, who all were safely evacuated in spite of having to pass over a long stretch of open ground exposed to fire. Through all this trying time he was cool and cheerful, showing a complete disregard of personal danger.

Capt. HENRY WILSON.—For conspicuous gallantry and devotion to duty. For five days, under all kinds of enemy fire, he showed an utter contempt of danger and disregard of self. His energy and splendid behaviour undoubtedly saved many lives, and through his powers of organisation no wounded were left behind when the battalion was relieved from the line.

* Since deceased. See Obituary, THE LANCET, May 4th, p. 653.

The following awards to, and promotions of, medical officers are in connexion with operations in East Africa :—

C.M.G.—Col. G. W. Tate, D.S.O., A.M.S.; Lt.-Col. R. G. Turner, D.S.O., I.M.S.

To be Brevet Lieutenant-Colonel.—Maj. (temp. Lt.-Col.) W. Benson, D.S.O., R.A.M.C.

Distinguished Service Order.—Lt.-Col. A. C. Adderley, R.A.M.C.; Temp. Maj. (acting Lt.-Col.) T. M. R. Leonard, Spec. List, West African Medical Service; Capt. (acting Maj.) A. McW. Green, South African, M.C.

Military Cross.—Capt. F. M. Barnes, R.A.M.C., Spec. Res.; Capt. H. D. Brown, R.A.M.C., Spec. Res.; Lt. N. S. Bruce, R.A.M.C., Spec. Res.; Temp. Lt. G. Burnet, R.A.M.C.; Capt. H. A. Crouch, R.A.M.C., Spec. Res.; Temp. Capt. M. C. Gardner, R.A.M.C.; Temp. Capt. E. Gibson, Spec. List, West African Med. Serv.; Capt. J. B. Lapsley, I.M.S.; Capt. G. S. Lawrence, R.A.M.C., Spec. Res.; Temp. Capt. T. H. Massey, East African Med. Serv.; Temp. Capt. H. R. Morehead, Spec. List, West African Med. Serv.; Temp. Capt. T. R. Sandeman, Spec. List, West African Med. Serv.; Capt. R. R. Scott, R.A.M.C., Spec. Res.; Capt. A. F. Wallace, Northern Rhodesia Med. Serv.

GALLANTRY AT SEA.—Surgeon E. A. Fiddian, R.N., has been awarded the bronze medal for gallantry in saving life at sea for assisting in the rescue of a shipwrecked British crew last January in the White Sea.

THE RED CROSS WAR HOSPITALS.—The annual report on the accounts of Auxiliary Hospitals in the British Isles for the year 1917 is a document which should prove of considerable value to all concerned in the control and support of those institutions, for the comparison of the working and expenditure between individual hospitals must lead to economy of administration. The report calls attention to the improvement in organisation, gives in detail the accounts, the number of patients treated indoors and outdoors, the cost of maintenance, and so forth. The number of hospitals dealt with is 1073, as compared with 960 in the report for 1916 and 753 in that for 1915. The average cost of maintenance per in-patient per day in 1917 was slightly in excess of 3*s.* 7*d.*, the average total cost of each in-patient for treatment being £7 3*s.* 5*d.* The total expenditure of the hospitals during the year was £3,466,892, as compared with £2,142,182 in 1916 and £1,023,937 in 1915. The total cost of maintenance was £3,144,362, the figures for 1916 being £1,937,221 and for 1915 £891,342. The total cost of administration for 1917 was £19,930. The report can be obtained from Room 46, 83, Pall Mall, London, S.W. 1, price 3*s.*

URBAN VITAL STATISTICS.

(Week ended August 3rd, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 12·1, against 13·1 and 13·1 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 11·4, or 0·4 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 3·0 in Cambridge, 5·1 in Swindon, and 5·8 in Wimbledon, to 20·2 in Exeter, 20·6 in Sunderland, and 31·5 in Aberdare. The principal epidemic diseases caused 255 deaths, which corresponded to an annual rate of 0·8 per 1000, and included 74 from infantile diarrhœa, 66 from measles, 63 from whooping-cough, 39 from diphtheria, 11 from scarlet fever, and 4 from enteric fever. The deaths from whooping-cough were the lowest recorded in any week of the current year; the deaths from measles and diphtheria showed a slight increase over the numbers recorded in the previous week. The 766 cases of scarlet fever and 927 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital were 21 and 34 below the respective numbers remaining at the end of the previous week. The 878 deaths from all causes in London included 38 from influenza, against 287, 192, and 86 in the three preceding weeks. The causes of 31 deaths in the 96 towns were uncertified, and included 5 in Liverpool.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 13·1, against 17·4 and 14·2 per 1000 in the two preceding weeks. The 280 deaths in Glasgow corresponded to an annual rate of 13·1 per 1000, and included 13 from infantile diarrhœa, 6 from whooping-cough, 5 from diphtheria, 3 from measles, and 1 each from enteric fever and scarlet fever. The 79 deaths in Edinburgh were equal to a rate of 12·4 per 1000, and included 1 each from whooping-cough and from infantile diarrhœa.

Irish Towns.—The 122 deaths in Dublin corresponded to an annual rate of 15·9, or 4·1 below that recorded in the previous week, and included 2 from infantile diarrhœa, and 1 each from enteric fever and measles. The 113 deaths in Belfast were equal to an annual rate of 15·0 per 1000, and included 7 from infantile diarrhœa and 2 from whooping-cough.

DONATIONS AND BEQUESTS.—The late Mrs. Elizabeth Tupper has left among other bequests £3000 each to the Cancer Hospital, the Hospital for Consumption and Diseases of the Chest, Brompton, St. Mary's Hospital, and Middlesex Hospital; £2000 each to University College Hospital, Gower street, the Royal Hospital for Incurables, Putney, Royal Naval Benevolent Society, Guy's Hospital, the Samaritan Free Hospital for Women and Children, Seamen's Hospital Society, the National Hospital for the Paralysed and Epileptic, and the London Hospital; £1000 each to the Society for the Prevention of Cruelty to Children, the Infant Orphan Asylum, Wanstead, the Royal London Ophthalmic Hospital, and the Earlswood Asylum for Idiots; and £500 to the Society for the Prevention of Cruelty to Animals.—By the will of the late Mr. Gunner Henry Patteson Strong the testator bequeathed £1000 to Guy's Hospital to endow a bed and £300 to the Dunster Cottage Hospital, Somerset.

Obituary.

FREDERICK THOMAS ROBERTS, M.D., F.R.C.P. LOND., D.SC. UNIVERSITY OF WALES,

CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND THE BROMPTON HOSPITAL FOR DISEASES OF THE CHEST.

WE announced last week the death of Dr. Frederick Roberts in his seventy-ninth year, who for a long period was one of the best known physicians in London, alike for his scientific opinions and as a teacher and an author. A Welshman by birth, he commenced his medical career by entering the Medical College at Liverpool, whence he proceeded to University College, London, joining the medical school. In the examination for the medical degree he was gold medallist in anatomy and physiology in 1860, became M.R.C.S. Eng. in 1861, B.Sc. Lond. in 1862, and graduated in medicine the following year.

After holding for a brief space of time the appointment of assistant physician to the Liverpool Northern Hospital, he returned, as was inevitable with his excellent student record, to University College, London, and in 1870, in which year he took the M.R.C.P. and the M.D. Lond., was appointed demonstrator of anatomy. The appointment marked the beginning of a great change in the system of medical instruction in the school. The system of teaching by "demonstrations" had begun to make its way elsewhere, but had not been adopted at University College. There were no demonstrations. There were, indeed, two demonstrators of anatomy who looked into the dissecting-room for a couple of hours every day. But that was all. The students had their lectures and their books, and they really did dissect; but for the most part they had to work out their own salvation with their own brains and discussions amongst themselves. The plan was a good one at bottom, but superior direction was lacking. Roberts came from Liverpool a fresh young man and full of energy, having lectured on almost every subject in the medical curriculum, his mind stored with an infinite variety of facts which were easily accessible and carefully arranged with all the method of a card-index. He at once started in the dissecting-room some excellent demonstrations on the convolutions of the brain, an innovation, as some of those who had almost finished their anatomy thought, and they proudly, perhaps conceitedly, held aloof from them. But Roberts's example was quickly followed in other departments, and demonstrational instruction and revision classes (and what are popularly known as "grinds") soon became as common at University College as everywhere else.

Roberts was a first-rate teacher of anatomy, as he soon had the opportunity of showing, for the professor, George Viner Ellis, fell ill, and the task of giving the set anatomical lectures devolved on his junior for a considerable time. It was not long before he joined the hospital staff as assistant physician, and those who had attended his anatomical lectures and demonstrations, and afterwards followed him in the out-patient room and the wards, could not fail to observe that his clinical and systematic lectures were arranged upon the familiar pattern. With him everything naturally fell into the tabular form—history, etiology, pathology, diagnosis, and treatment; and, though the students sometimes made fun of it, they found it an invaluable help in arranging their own ideas, not only for permanent use, but for the more transient requirements of the examination-room. His lists of the causes of any particular physical sign or symptom were most carefully prepared, and looking back it is interesting to remember how often "bad teeth" took almost as prominent a place as "pyorrhœa" takes to-day.

In 1877 Roberts became F.R.C.P. Lond. and in the following year full physician to the hospital. In his visits in the wards it was Roberts's special delight to demonstrate to his class the methods of percussion and auscultation, and Sir William Jenner used to refer students to him to learn how to percuss a chest. No little amusement was often elicited in comparing his light, fully-trained touch with the heavy, almost rib-breaking efforts of the new clinical clerk. In his appreciation of slight variations in the percussion note and the quality of cardiac murmurs his accurate musical ear stood him in good stead. It is always well that in a medical school different methods of clinical teaching should be represented, and this was strikingly the case at University College Hospital when Roberts first took charge of wards, with Wilson Fox, Ringer, and Bastian as his senior colleagues. His clinics were always crowded, and in addition to his sound and clear teaching there was a natural *bonhomie* about him which captivated the students and was better than a dose of medicine for the patients, who looked forward to his visit like a tonic. In remembering Roberts as a teacher, not a few will call to mind his course of lectures as Professor of Materia Medica. The subject as then taught was at the best not an exhilarating one, but somehow Roberts succeeded in making it attractive to a large and attentive class, and there must be many who, carrying their memories back to the early eighties, will recall the carefully prepared definitions of the various groups of therapeutic agents, among which that mysterious group, the "alteratives," must have proved particularly difficult for the lecturer to put in its right place. It was almost a matter of course that Roberts should write a handbook of medicine; and a very successful venture it was. Its title was the "Theory and Practice of Medicine." It passed through many editions and grew into a huge volume. As we turn its pages we find again, as in his anatomical and clinical teaching, everything falling into its proper pigeon-hole with charming accuracy and precision.

Thinking of all these things, and of how good a physician he was, and how large his public—for it must be remembered that he was also physician to the Brompton Hospital—one wonders how it was that Roberts did not secure one of the first consulting practices in London. It is impossible to specify the exact combination of qualities that lead up to complete success. Not that Roberts failed in this respect. He was busy enough. But he often spoke of his practice with some disappointment, and said that he would have done much better if he had gone on the operatic stage, till sometimes the thought arose whether his great reputation as a singer might have interfered with his reputation as a physician. Be that as it may, he certainly had the musical gifts of his race developed to the highest degree and an incomparable tenor voice, and a manner and style that made the trivial words of a light song go to your very heart. It was a voice without an edge, and till he was quite an old man Roberts's songs were always looked forward to and encored at Brompton dinners, at the annual University College festivals, and in his own house in Harley-street, where the music room was a shrine, and where the generous repast was always followed by a musical treat of the highest order.

Dr. Sidney Martin writes:—

Frederick Roberts was appointed assistant physician to University College Hospital at a time near the end of William Jenner's great career as pioneer in medicine and clinical teacher in the medical school. He was a pupil of Jenner, and was, like all others who came under his influence, profoundly affected by his teaching and personality. Roberts soon obtained a definite position in the medical school as the result of his industry and clinical teaching. He was not an original worker or thinker; but his mind was very methodical and his definition clear, so that his clinical demonstrations were highly appreciated, more particularly by the junior students. There were, indeed, some who were inclined to belittle his method of teaching, which perhaps classified the symptoms of disease in too methodical a manner. But there is no question that his method was of great value to many who were beginning the study of medicine at the bedside. His systematic lectures were always clear expositions of the subject. For some years he lectured in the particularly dull subject of materia medica with success. His lectures in medicine did not, like those given by Russell Reynolds and Ringer, deal with pictures of disease, but consisted in a categorical statement of the symptoms of particular disease; a method useful, indeed, for examinations, but not sufficiently stimulating, perhaps, for the thinking student. During the whole of his career at the staff of the hospital Frederick Roberts maintained his energy in teaching; he was always ready to help the student, and thus became a most important member of the medical school. Numerous are the practitioners of medicine who are grateful to him for his clear exposition of the symptoms of disease.

Roberts's active career in the medical school was at a period before the development of bacteriology, so that he was not in touch with the recent developments of medicine. If anything he belonged to the school of Walsh, which spent itself in the minute examination of the physical signs of

disease. This is a useful aspect of clinical medicine, but its too exclusive study is apt to obscure a wide view of the study of disease. As a colleague Roberts was delightful and loyal to his colleagues, to the school, and upright in all his dealing. There was no better friend to have, and his beautiful singing will remain in the hearts of his friends for all time.

Dr. Walter Carr writes:—

Among the many distinguished members of the medical staff of University College Hospital during the last quarter of the nineteenth century Dr. F. T. Roberts was in several respects an out-standing figure. His imposing personal appearance, his unfailing *bonhomie*, the special characteristics of his teaching, his many acts of personal kindness, his magnificent and well-trained voice, all combined to make him exceptionally popular with successive generations of students. Who can forget the way in which he would stride into his ward and, standing by the bedside of a patient, commence a clinical lecture on the causes of some particular symptom—"Firstly, nothing at all; secondly, bad teeth; thirdly .....," and so on, until every likely or unlikely cause had been discussed. Classification was of the essence of his teaching alike in the wards, in his systematic lectures on therapeutics, and in his well-known text-book on Medicine. Possibly the method was carried too far, as it tended to attach equal importance to frequent and to rare causes of disease, to common and to exceptional symptoms, to all-important and to comparatively valueless drugs; nevertheless, it served to make us thorough in the investigation of cases and to diminish the risk of our overlooking or forgetting less important causes or symptoms. Incidentally it was most valuable for the immediate purpose of helping us to pass examinations.

In some respects Roberts was in advance of his time. He impressed upon us the importance of the teeth at a period when they were only too frequently entirely disregarded and when pyorrhœa was as little thought of as were adenoids. He often foretold that a day would come when diseases of the pancreas would figure far more prominently in medicine than was then the case. Perhaps he was at his best when passing comparatively quickly from bed to bed he would make a few pertinent remarks on the salient features of each case. From his special experience at the Brompton Hospital, aided doubtless by his fine ear for sound, he was naturally particularly interested in lung diseases, and his pupils are never likely to forget the importance he very rightly attached to pleural adhesions and, above all, to "mixed morbid conditions in the chest." Only a few years ago the writer of these notes published a clinical lecture on this subject in one of the medical journals, in which he referred to his indebtedness to his old teacher. A few days later he received a characteristically kindly letter of thanks from Roberts, in which he said how often others had appropriated his teaching without any acknowledgment whatever.

The amount of work which Roberts got through, apparently without undue strain or effort, must have been enormous. In addition to a large private practice, he was regular in his attendance and teaching at two important hospitals; he was constantly bringing out a new edition of his popular book on medicine, not to mention a good deal of other literary work; he was a very active Fellow of the Medical Society of London, finally becoming President; and he seemed positively to revel in examinerships, of which he held a remarkable number. Nevertheless, he found time also for an unusual amount of social life, and no account of him would be complete without a reference to his quite exceptionally fine tenor voice, which fully maintained the traditional reputation of his native country—Wales—as a home of song.

Roberts retired from the active staff of University College Hospital in 1905, and his closing years were a period of enforced quietude and retirement, pathetic by contrast with the strenuous activities which have been set out above. He was a great figure in medical education during the last quarter of the nineteenth century.

HENRY BETHAM ROBINSON, M.D., M.S. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO ST. THOMAS'S HOSPITAL; SURGEON TO KING GEORGE HOSPITAL; MAJOR, R.A.M.C. (T.).

WE recorded last week the death on July 31st, in his 58th year, of Mr. H. B. Robinson, senior surgeon to St. Thomas's Hospital, and lecturer on surgery in the Medical School.

Henry Betham Robinson was born in August, 1860, received his school education at Dulwich College, and entered the medical school of St. Thomas's Hospital, London, where he won many distinctions, amongst them the scholarship and gold medal in medicine at the London M.B. examination (1885) and the gold medal for the B.S. In 1887 he became a Fellow of the Royal College of Surgeons of England, and was appointed Hunterian Professor in 1893, giving a course of lectures on Cystic Diseases of the Breast. In the same year he was elected on the surgical staff of his hospital, ascending the scale until at the time of his death he was senior surgeon on the acting staff, as well as consulting surgeon to two children's hospitals in the East End. His services as a teacher were largely in demand. He was the last surgeon on the staff to give lectures on anatomy at his medical school, and until his death he held the lectureship on surgery, the entire systematic course falling on him during the winter months owing to the absence of a colleague. For many years he was examiner in surgery at the Universities of London and Manchester. As surgeon at St. Thomas's Hospital he held a Territorial commission, and in August, 1914, he was called up and attached as *à la suite* officer to the Second London General Hospital. Soon after he accepted a similar appointment at the newly opened King George Hospital, and in 1915, when the military side of St. Thomas's became No. 5 London General Hospital, he took charge of beds there as well. Thus for three years he worked incessantly at three military hospitals as well as his civil ones, and only during the last few months was he relieved of beds at the first named. These exhausting years, in which his energies never seemed to flag, contributed doubtless to his early breakdown.

As a surgeon Mr. Robinson was notable for the thoroughness of his methods, combined with a quickness which was never practised at the expense of the patient. He was an excellent diagnostician, particularly in abdominal affections. For some years he was in charge of the throat department at St. Thomas's Hospital, after he had left it retaining both his skill and interest in that line of work. As a teacher he was an unfailing attraction to the students. He had a good delivery, formed clear opinions, and enunciated them in well-chosen but simple language. A factor in his success was the evident enjoyment that teaching gave him, and he still retained his ward-classes after ill-health had obliged him to give up operating. Mr. Robinson also wrote with a clear and trenchant style, but apart from an article in Quain's Dictionary and reports of cases in weekly and monthly journals his busy life gave him little time for literary work, and it is feared that his researches on the diseases of the mammary gland may remain unrecorded.

Of the personal characters which made Mr. Robinson such a popular figure at his school an intimate friend writes:—

"Even a stranger might have realised the mingled affection and respect with which Robinson was regarded by all at St. Thomas's if he happened to be a guest in the operating theatre and saw the surgeon, the dressers, and the nurses all bubbling together over some little touch of humour on the part of their chief which he unaffectedly enjoyed at least as much as the rest. This element of simplicity in his character made it possible for him to enter naturally into the social life of the school. His participation in the staff race was a feature at the annual sports. In his student days he had been a regular playing member of what might be called the 'ever-victorious' Rugby football team of the 'eighties,' and this was one of his most cherished recollections."

Mr. W. H. Battle sends us a further appreciation:—

"Mr. H. B. Robinson was a man whose earnestness of endurance was crowned by thoroughness of performance. There were few days on which he spent less than five hours at the operation table, and those associated with him appreciated more and more his accuracy of diagnosis and judgment, as well as his skilful operative work. There can be little doubt in the minds of those who know the immense amount of work which he did during the last three-and-a-half years of his life, that he sacrificed himself on the altar of duty quite as much as the man who goes abroad and dies there from one of the risks incidental to warfare in the field. Those of us who are left have to mourn the loss of a good colleague and faithful friend. His quiet unassuming life was an example to the profession; he let his efficient performance of duty and practical knowledge speak for him. Shortly before his illness necessitated absolute retirement he had the satisfaction of admitting his only son to the Cheselden Lodge of Freemasons, of which he himself was Master at his death."

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the recent Final Examination, held from July 9th to 22nd, the following candidates were approved in the subjects indicated, but are not eligible for diplomas:—

Medicine.—W. M. Anthony, St. Thomas's; B. A. Astley-Weston, Bristol; P. Banbury, St. Thomas's; L. H. Bartram and F. T. Burkitt, Cambridge and St. Bart.'s; D. Campbell, M.D. New York, New York; Elizabeth Casson, Bristol; N. Cheua, Middlesex; C. B. Clarke, Cambridge and Univ. Coll.; W. Davies, London; Mary Day, St. Mary's; G. B. Dowling, Guy's; C. C. R. Downing, Cambridge and Univ. Coll.; H. Franklyn, Cambridge and St. Bart.'s; L. E. Frazer, Cambridge and St. Thomas's; W. A. Freedman, M.B., B.S. Durh., Durham; C. F. Good, London; Dorothy Winifred Gowers, Royal Free; W. R. G. Harris, London; F. Y. Hasaballa, Charing Cross; A. T. Hawley, Cambridge and St. Thomas's; E. T. Holden, Birmingham; A. W. Holgate, Univ. Coll.; A. St. G. J. M. Huggett and G. R. Hull, St. Thomas's; E. H. Johnson, Manchester; R. D. Jones, St. Bart.'s; F. W. Kemp, Charing Cross; H. W. Kerfoot, M.D., C.M. McGill, McGill; P. C. Livingston, Cambridge and London; T. D. Llewelyn, Cardiff and St. Thomas's; W. K. McKay, Guy's; T. C. McKenzie, Birmingham; C. F. McLean, Cambridge and St. Thomas's; C. D. Maitland, St. Thomas's; G. Millar, St. Bart.'s; F. Morcos, St. Mary's; W. A. W. Parkes, Birmingham; E. A. Pearson, London; H. J. A. Pollard, Cambridge and St. Bart.'s; H. L. Pridham, St. Bart.'s; F. A. Prosser, Liverpool; F. W. Reitz, Guy's; E. D. T. Roberts, St. Thomas's; L. I. Roberts, Univ. Coll.; R. H. O. B. Robinson, Cambridge and St. Thomas's; R. J. Saunders, London; Hilda Norah Shufflebotham, M.B., Ch.B., B.Sc. Birm., Birmingham; C. G. D. Siggs, Guy's; J. Spira, Brussels and St. Thomas's; F. H. Stuttaford and A. C. Teuten, St. Mary's; J. E. de V. van der Merwe, Guy's; W. E. M. Wardill, M.B., B.S. Durh., Durham; F. F. Wheeler, St. Mary's; E. C. Whitehall-Cooke, St. Thomas's; J. M. Winnett, London; and G. Winter, Birmingham.

Surgery.—J. C. Andrews, Cambridge and London; J. B. Barnett, Birmingham; H. F. G. Berncastle, Guy's; W. L. Berry, St. Bart.'s; J. M. Brydson, Durham and London; H. C. H. Bull, St. George's; W. M. Casper, Cambridge and St. Bart.'s; R. A. Cooke, Liverpool; C. F. Eminson, Charing Cross; G. A. Fisher, Cambridge and St. Bart.'s; G. A. Goolden, Cambridge and St. Thomas's; P. E. Gorst, Liverpool; F. Gray, B.A. Cantab., Cambridge and St. Bart.'s; E. G. T. Holden, Birmingham; C. M. Jones, Cambridge and Liverpool; E. G. Joseph, Edinburgh; V. J. F. Lack, London; P. Lloyd-Williams, St. Thomas's; G. L. Lyon-Smith, Cambridge and St. Bart.'s; H. C. McAlister, M.B. Tor., Toronto; E. K. Macdonald, St. Thomas's; R. S. Ralph, Guy's; A. H. J. Smart, Cambridge and St. Thomas's; E. E. R. Spurway, M.B., Ch.B. Birm., Birmingham; A. E. Ward, St. Thomas's; W. E. M. Wardill, M.B., B.S. Durh., Durham; and R. Wolff, B.Sc. Cape Univ., L.D.S. Eng., Middlesex.

Midwifery.—I. M. Abd-El-Said, Univ. Coll. Hosp.; N. S. Alder, St. Thomas's; J. H. Allan, Liverpool; G. W. Almeyda, London; Marjorie Back, Royal Free; H. Barbash, Cambridge and St Bart.'s; G. A. E. Barnes and B. F. Behman, Univ. Coll.; F. J. Bennett, Cambridge and Manchester; M. Z. Bochenek, London; G. A. A. Bradnack, Guy's; P. J. Briggs, Cambridge and Guy's; Ella Marianne Britten, St. George's; Anna Bridget Broman, Royal Free; H. Brookman, Middlesex; O. H. Brown, Charing Cross; J. M. Brydson, Durham and London; D. Campbell, M.D. New York, New York; Elizabeth Casson, Bristol; Marjorie Carnsew Chappel, Royal Free; H. B. Cole, Cambridge and St. Bart.'s; P. C. Collyns, St. Bart.'s; R. A. Cooke, Liverpool; J. C. Davies, St. Bart.'s; Mary Day, St. Mary's; J. P. de Silva, London; J. C. Dixey, Oxford and St. Bart.'s; G. B. Dowling, Guy's; R. H. Emmett, Cambridge and St. George's; R. S. Foss, St. Thomas's; E. J. Gaffney, L.D.S. Eng., Guy's; J. F. Gaha, Dublin; W. Göthe, Middlesex; C. Grantham-Hill, Cambridge and London; F. Gray, Cambridge and St. Bart.'s; C. H. Gunasekara, Cambridge and Middlesex; B. C. Hardiman, M.D., C.M. Queen's Univ., Queen's Univ., Ont.; Joan Margaret Redford Harris, Royal Free; O. S. Hillman, Middlesex; H. C. Hopkinson, Cambridge and Manchester; C. McC. Jones, Cambridge and Liverpool; E. G. Joseph, Edinburgh; H. Kamal, King's College; H. D. Kelf, St. Bart.'s; M. A. Keshvalu, Hyderabad and Univ. Coll.; R. B. P. Lansdown, Cambridge and Guy's; F. W. Lemarchand, St. Bart.'s; G. L. Levin, Univ. Coll.; L. Lyne, Guy's; Elizabeth Esther McCulloch, Liverpool; E. D. Macmillan, St. Bart.'s; Malati Madgavkar, Birmingham; A. A. E. S. Mansour, Charing Cross; T. Mensa-Annan, Cambridge and King's College; A. Mishriky, St. Mary's; G. T. Mody, M.B., B.S. Bombay, Bombay and Bristol; Eva Morton, Royal Free; C. F. Newman, Birmingham; V. A. Newton, Birmingham; W. H. Palmer, Cambridge and St. Thomas's; C. A. Paulusz, L.M.S. Ceylon, Ceylon and Guy's; G. A. Pennant, Cardiff and Bristol; F. L. Pickett, Manchester; F. A. Prosser, Liverpool; Enid Margaret Mary Quaife, Royal Free and St. Mary's; W. Reikan, Manchester; B. R. Reynolds, Cardiff and Bristol; Hilda Winifred Richards, St. George's; W. A. Richards, Cardiff and Charing Cross; J. C. R. Richardson and H. S. Robinson, London; J. C. Russell, Cambridge and London; Hilda Nora Shufflebotham, M.B., ChB., B.Sc. Birm., Birmingham; L. A. Simaika, St. Bart.'s; J. V. A. Simpson, Middlesex; Mary Sylvia Stocks, Royal Free and St. Mary's; C. E. Taylor, Cambridge and Univ. Coll.; A. L. Telling, Leeds; D. V. Townshend, Birmingham; R. W. Warrick and E. R. Webb, Guy's; G. A. O. White, Middlesex; R. L. Williams, Cambridge and St. Bart.'s; Ethel Dorothy Willis, Manchester; M. Wong, Cambridge and St. Thomas's; S. C. Woodhouse, London; C. Young, Middlesex; and F. Young, Guy's.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—During next week clinics will be held each week-day at 2 P.M., Wednesday, Friday, and Saturday also at 10 A.M.

WOMEN STUDENTS AT UNIVERSITY COLLEGE HOSPITAL.—The General Committee of University College Hospital has decided to admit women students to the hospital and medical school from Oct. 1st next. The Faculty of Sciences at University College has been open to women since 1877, and the Faculty of Medical Sciences since October, 1917. Women will thus now be able to take their whole medical course at University College and University College Hospital, and to avail themselves of the arrangements made with the National Hospital for the Paralysed, Queen-square, the Hospital for Sick Children, Great Ormond-street, and the Central London Ophthalmic Hospital, Judd-street, for students of University College Hospital to carry out a portion of their clinical studies at these special hospitals.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—This association held its annual meeting at its offices, 34, Copthall-avenue, E.C. 2, on June 27th. As the President, Surgeon-General G. J. H. Evatt, C.B., was detained on military duties the chair was taken by Dr. A. A. Napper. The annual report showed considerable activity and an addition of 31 new members. The rules were revised and a discussion on the Poor-law and its future followed. The honorary secretary, Dr. A. Withers Green (City of London) read a short paper on the Future of the Poor Law. The subject was taken up by Lieut.-Col. C. Thackray Parsons, R.A.M.C., of Fulham Military Hospital, at some length, as well as by Dr. E. Claude Taylor, of the Hampstead General Hospital. Considering war conditions the meeting was well attended and the interest sustained. A full report will be found in the coming number (August 10th) of the *Medical Officer*, published at 36, Whitefriars-street, E.C., which is sent free to each member of the association whenever it contains an inset from the Poor-law Medical Officers' Association. Council meetings are held quarterly at the above offices. The annual subscription is 5*s*. It would be well if the Poor-law medical officers of each county or district were to meet together to discuss their interests, especially in view of probable coming changes, and send their conclusions to the honorary secretary.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on July 24th, with Sir Francis H. Champneys in the chair. Certain midwives were struck off the roll, the following charges amongst others having been brought forward:—

A midwife being in attendance at a confinement she neglected to disinfect her hands and forearms on each occasion before touching the generative organs of the patient, as required by Rule E. 4; she neglected to wash the patient's external parts with soap and water and then to swab them with an efficient antiseptic solution (1) before making the first internal examination; (2) after the termination of labour; (3) during the lying-in period, as required by Rule E. 8. A child suffering from inflammation of, and discharge from, the eyes the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5). A midwife neglecting to take and record the pulse and temperature of the patient at each visit, as required by Rule E. 14; neglecting to enter her records of pulse and temperature in a notebook or on a chart carefully preserved, as required by Rule E. 14. Not being scrupulously clean in every way, as required by Rule E. 2, and not keeping her register of cases as required by Rule E. 24. Having been in contact with a person suffering from puerperal fever the midwife neglected to notify the local supervising authority thereof, as required by Rule E.22 (1) (e); that in the years 1917 and 1918, with intent to avoid inspection by the local supervising authority, she falsely represented to the Inspector of Midwives of the London County Council that she was not practising or intending to practise as a midwife, but only as a maternity nurse under medical practitioners. Medical aid having been sought for a patient the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (a); she did not on each occasion when attending the patient wear a clean dress of washable material, as required by Rule E.2. A child suffering from serious skin eruptions marked by the formation of watery blisters, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5); discontinuing her attendance at a time when the conditions of both mother and child were abnormal, in disregard of Rule E. 12, and entering in her chart lists of temperature and pulse purporting to record the daily temperature and pulse of the patient, well knowing that such entries were false.

At a meeting held on July 25th a letter was considered from the medical officer of health for the county of Durham asking:—

(*a*) Whether any objection can be raised to a registered medical practitioner employing a certified midwife to attend his midwifery cases, the midwife being paid a fixed salary for her attendance, including the collecting of fees due to her employer and paying them over to him. (*b*) Whether in such a case the midwife is bound to continue her attendance on the patient for ten days after the confinement or can she hand over the conduct of the case during the lying-in period to her employer. (*c*) What action should be taken by a county council desirous of appointing a subsidised midwife in a district not adequately provided with trained midwives where the local medical practitioners object to her appointment unless they receive a guarantee for the payment by the county council of their fees when called in on the advice of the midwife, whether the patient can afford to pay the fee or not.

The Board decided that the reply be:—

(*a*) That there is no objection to such an arrangement. (*b*) That under the circumstances specified the midwife is bound to attend for the period of ten days after the labour. (*c*) That as the County Council subsidises the midwife it ought to hold itself responsible for the payment of the doctor when required.

It was unanimously resolved that in the opinion of the Board it is desirable to pass the following resolutions, to come into effect if and when Clause 10 of the Midwives Bill, 1918, becomes law:—

(*a*) That having regard to the equivalent value of the standards of training and examination required by the Central Midwives Board for Scotland and by this Board it be an instruction to the secretary to admit to the Roll of Midwives, subject to compliance with the terms and conditions of Section 10 of the Midwives Act, 1918, any woman holding the certificate of the Central Midwives Board for Scotland in virtue of having passed the examination of that body, and to report his action to the Board. (*b*) That in the case of a woman applying to be certified under Section 10 of the Midwives Act, 1918, by reason of any qualification other than that of holding the certificate of the Central Midwives Board for Scotland in virtue of having passed the examination of that body, the secretary do report thereon for such action to be taken as the Board may deem expedient.

BRITISH SCIENTIFIC PRODUCTS EXHIBITION.—Under the auspices of the British Science Guild an exhibition of four weeks' duration will be held at King's College, London, during August and September, with the object of emphasising the need for scientific research and for the application of its results to the arts and industries. The exhibits will include chemical, electrical, surgical, bacteriological, and pathological appliances, optical apparatus, and various processes in food production and conservation, with the intent to show that by the combination of science and industry this country "has done nearly as much in the four years of war as the Germans did in the preceding 40"—this being the claims of the organisers.

NOTES ON CURRENT TOPICS.

Medical Treatment of School Children.

THE Lords amendments to the Education Bill have been agreed to by the House of Commons. A new clause setting out the provisions as to medical treatment of school children has been thus assented to in the following terms:—

"A local education authority shall not in exercise of the powers conferred upon them by paragraph (*b*) of Subsection (1) of Section 13 of the Education (Administrative Provisions) Act, 1907, or by this Act, establish a general domiciliary service of treatment by medical practitioners for children or young persons and in making arrangements for the treatment of children and young persons a local education authority shall consider how far they can avail themselves of the services of private medical practitioners."

EDITORIAL NOTICE.

In consequence of the pressure on our space and the shortage of paper, the Editor may be compelled to abbreviate communications, as an alternative to their rejection, when time does not allow them to be reconsidered by their authors.

Communications, Letters, &c., to the Editor have been received from—

A.—Association of Certifying Factory Surgeons, Manchester, Hon. Sec. of; Association of Public Vaccinators of England and Wales, Lond.; Col. J. G. Adami, A.D.M.S.

B.—Capt. W. Brown, R.A.M.C.; Mrs. Cloudesley Brereton, Lond.; Dr. P. Bousfield, Lond.; Board of Agriculture and Fisheries, Lond.; Dr. M. K. Barradah, Cairo.

C.—Capt. C. M. Craig, R.A.M.C.; Lieut. T. E. Coulson, R.A.M.C.; Colonial Office, Lond., Private Sec. of; Mr. A. C. Chapman, Lond.; Dr. W. Carr, Lond.; Dr. E. L. Collis, Lond.; Dr. W. L. Cowardin, Oban; Capt. D. W. Carmalt-Jones, R.A.M.C.(T.)

V.—Vitamogen, Ltd., Lond.; Mr. S. K. Vaidya, Lond.

Offices: 423, STRAND, LONDON, W.C. 2.

Appointments.

BOURNE, A. W., M.B., has been appointed Temporary Obstetrician and Gynæcologist at the Municipal Hospital of the Willesden Urban District Council.

HUNTER, ALLISON MARY, Temporary Resident Assistant Physician at Ruchill Hospital, Glasgow.

Vacancies.

For further information refer to the advertisement columns.

Birmingham University.—Sen. Demonstrator of Anatomy. £250.
Blackburn County Borough.—Two Asst. M.O.H. £500.
Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200.
Bramcote Sanatorium, Nuneaton.—Res. M.O. £300.
Brighton County Borough Asylum, Haywards Heath.—L.T. Asst. Res. M.O. £7 7*s.* per week.
Brighton, Royal Sussex County Hospital.—Jun. H.S. £80.
Bristol Royal Infirmary.—H.P. and H.S. £120.
Cheltenham Eye, Ear, and Throat Free Hospital.—Asst. S. £400.
East Ham Education Committee.—Temp. Asst. School M.O. £350.
Glasgow, Govan District Asylum, Cardonald.—Sen. Asst. M.O. Also Locum.
Great Northern Central Hospital.—Casualty Officer. £200.
Manchester, Ancoats Hospital.—Sen. H.S. £250.
Manchester County Asylum, Prestwich.—L.T. £7 7*s.* per week.
Manchester Royal Eye Hospital.—Sen. H.S. £120.
Middlesex Education Committee.—Asst. School M.O. £400.
Middlesex Hospital, W.—Obstet. and Gynæco. H.S.
Newcastle-upon-Tyne Education Committee.—Asst. School M.O. £350.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Anæsthetists.
Norwich, Norfolk and Norwich Hospital.—H.S. £400.
Nottingham General Hospital.—Two Female H.S. £250.
Nottingham, Ransom Sanatorium, Mansfield.—Res. M.O. £250.
Notts Education Committee.—Asst. Sch. M.O. £400.
Rainhill, nr. Liverpool, County Asylum.—Temp. Asst. M.O. 7 gs. wk.
Rochdale Infirmary and Dispensary.—Jun. H.S. £150.
Sheffield Royal Infirmary.—Res. S.O. £200. Also H.S. £150.
Stoke-on-Trent County Borough.—Asst. Tuberc. O. £360.
Sunderland, Durham County and Sunderland Eye Infirmary.—Locum.
Walsall General Hospital.—Female H.S. and Anæs. £175.
West London Hospital, Hammersmith-road, W.—H.P. £4 4*s.* per week.
Whitehaven and West Cumberland Infirmary.—Res. H.S. £150 to £180.

Births, Marriages, and Deaths.

BIRTHS.

ALDRIDGE.—On July 31st, at Magdalene House, Glastonbury, Somerset, the wife of F. J. Aldridge, B.A., B.M., B.Ch. Oxon., of a son.

BENSON.—On August 2nd, at "Elmhurst," Devonshire-road, Sherwood, Nottingham, the wife of Lieutenant-Colonel W. A. Benson, D.S.O., T.D., R.A.M.C., of a son.

BUSHE.—On July 31st, at St. Hilary-terrace, Stoke, Devonport, the wife of Fleet Surgeon C. K. Bushe, R.N., M.D., of a son.

CHOPPING.—On August 4th, at Devonshire-gardens, Glasgow, the wife of Colonel Arthur Chopping, C.M.G., R.A.M.C., of a daughter.

HERDMAN-NEWTON.—On July 28th, at Tremorvah Lodge, Truro, the wife of Surgeon R. H. Herdman-Newton, R.N., of a son.

HILTON JONES.—On July 24th, at "Penygarth," Harlech, North Wales, the wife of Major R. O. Hilton Jones, M.C., R.A.M.C., of a son.

TATE.—On July 29th, the wife of Captain D. Laurence Tate, R.A.M.C., of a daughter.

MARRIAGES.

AITKEN—CHAPMAN.—On July 31st, at Commonhead House, Airdrie, Robert Aitken, M.B., Ch.B., Surgeon, Royal Navy, to Marion Adam, third daughter of Mr. and Mrs. William W. Chapman, Commonhead House, Airdrie.

DENNING—EMDIN.—On July 23rd, at St. Paul's Cathedral Church, Valletta, Malta, Surgeon Frederick Arthur Vere Denning, Royal Navy, to Daisy, only daughter of Engineer Captain A. R. Emdin, C.M.G., R.N.

FINDLAY—FORGAN.—On July 31st, at the British Consulate, Mukden, and at Wylie Memorial Church, Liaoyang, the Rev. James W. Findlay, M.A., to Margaret Rose Forgan, M.A., M.B., Ch.B.

DEATHS.

HOSKIN.—On August 5th, Theophilus Hoskin, M.R.C.S. Eng., L.R.C.P. Lond., aged 62.

ROBINSON.—On July 31st, Henry Betham Robinson, M.D., M.S., F.R.C.S., Major, R.A.M.C.(T.), Surgeon to St. Thomas's Hospital, of 1, Upper Wimpole-street, W., aged 57 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE Great Northern Central Hospital has received from the trustees of the will of Lieutenant Alexander Wernher the sum of £500 from the amount bequeathed by him for division amongst charities.

THE Combined Universities Conservative and Unionist Association has adopted Mr. Herbert G. Williams, M.Sc., as their candidate for the Parliamentary Division, which comprises the Universities of Durham, Manchester, Liverpool, Leeds, Sheffield, Birmingham, and Bristol.

Notes, Short Comments, and Answers to Correspondents.

THE SIGNIFICANCE TO MEDICINE OF THE CREATION OF A HEBREW UNIVERSITY AT JERUSALEM.

THE recent laying of the foundation stone of a Hebrew University at Jerusalem reveals the true spirit of the Jewish people. From the earliest times it has been considered by Jews to be a sin to live in a town in which there was no school, and now the provision, amidst the clash of arms, of means for higher education in the "place in the sun," which the British Government has promised to restore to them, expresses in the most emphatic manner the high value that the Jews continue to attach to intellectual and moral development.

Since antiquity the healing art has specially appealed to the Jew. In Talmudic times, although there was no indigenous school of Jewish medicine, enthusiasm for medical lore was great, partly because such knowledge was daily required for the elucidation of ritual observance. The administration of the dietary laws, for instance, demanded a thorough knowledge of morbid anatomy and pathology to be able to recognise post mortem whether an animal that was killed for food had previously suffered from disease likely to shorten its life, and thus render it *t'repha* or unfit for human consumption. The ancient Jewish Court of Justice often employed the services of a medical assessor in matters of medico-legal importance. Although much of the medical knowledge of the Talmudic period was imbibed by the Jews from their Roman and Greek contemporaries, yet there can be no doubt that they contributed a great deal to all the branches of medical science, for their opinions were often opposed to those of the Greek and Roman physicians.

In early post-Talmudic times—i.e., about the fifth or sixth centuries—laws were promulgated forbidding Jews to practise medicine, but in the seventh century the Arabian medical schools contained many Jewish students and teachers. In Egypt and Northern Africa most of the Court physicians between the sixth and the fourteenth centuries were Jews.

In modern and recent times the number of Jews who have distinguished themselves in medicine (either as practitioners or as investigators) and cognate sciences all over the world is out of all proportion to their population. The recital of such names as Henle, Remak, Cohnheim, Cohnstein, Zunz, Hermann, Hirsch, Romberg, Weigert, Weichselbaum, Ehrlich, Frankel, Neisser, Wassermann, Senator, Israel, and Baginski is sufficient confirmation of the statement that German medicine is to a large extent Jewish medicine. In the United States the names of Flexner, Jacques Loeb, Rosenau, and Solis-Cohen stand out pre-eminently; Italy with such men as Lombroso and Otolonghi; and even Russian medicine has had famous Hebrew names, although until the Revolution Jews were practically debarred from entering the universities.

With such a supply of talent amongst Jews it should not be difficult to fill the staff of a Hebrew University. Whether the creation of a special Jewish faculty will react beneficially upon medical science is difficult to foretell. An eminent Hebrew nationalist writer, when speaking of "the perennial spring of living creative power" among Jews, deplores the scattering of the Jewish genius among the cultures of other nations, instead of converging to a focus in a national culture of their own. The creation of a specifically Jewish place of higher study will afford the necessary facilities to those who possess the brains but lack the "golden key" or some other requirement for admission into a university. The intensive cultivation produced by concentration of effort under specifically Jewish surroundings will help some of that dormant Jewish talent to germinate which now dies for lack of stimulus. For this reason the medical faculty all over the world will welcome the establishment of a Hebrew University.

VITAMINES AND COOKING.

To the Editor of THE LANCET.

SIR,—I have charge of two grandchildren, aged 6 and 3, who enjoy excellent health on a diet of porridge, bread-and-butter and jam, vegetables, eggs, boiled milk, and a little meat, and occasional quantities of raw fruit. Except for the butter and fruit this is all cooked food. I know also some working-class families who live in good health on bread, margarine, potatoes, jam, tea, trifling quantities of milk, and meat once a week. Here again nearly all the food is cooked. These children ought not to be in such good health if it be true that vitamines, on the one hand, are necessary in small quantities for good health, and on the other that they are destroyed at a temperature of 100° C.—that is to say, by cooking. It is important that, if cooking destroys vitamines, the public should be told the evidence on which the statement is based. There is much evidence to the contrary, as in the case of the good health of the Scotch and Irish poor of past times, who lived on little else than cooked oatmeal and potatoes. The evidence of the prevention of beri-beri by a change from a diet of polished to unpolished rice is even more damaging to the view that vitamines are destroyed by cooking, for in both cases the rice is cooked.—I am, Sir, yours faithfully,

WALTER KIDD, M.D., F.R.S.E.

Alum Bay, Isle of Wight, August 3rd, 1918.

*** This important question was discussed in our columns several years ago (*vide* annotation, THE LANCET, March 21st, 1914, p. 841), and correspondence which followed upon it (March 28th (p. 931) and April 4th (p. 1002), 1914). It then seemed clear that some vitamines at all events were not destroyed at 100° C. Further studies since made suggest that though the heat employed in cooking impairs the efficiency of certain accessory food substances, it does not destroy them altogether. This is, as our correspondent points out, obviously the case with rice, since only cooked rice is consumed.—ED. L.

OCCUPATIONS FOR WOMEN.

UNDER the title of "Women's Work in War Time," Messrs. T. Werner Laurie, London, have issued (at the price of 1s.) a new edition of a useful little book compiled by Mrs. H. M. Usborne giving a brief sketch of occupations open to women in all spheres of life, including details of the training necessary for obtaining the appointments, its cost, and the emoluments which may be expected. The second part of the book contains short articles by various writers on such topics as "War Work and Future Prospects," women in the Civil Service and in agriculture, the care of school children, welfare work, and Red Cross work in the war.

PARASITIC MANGE.

A LEAFLET has been issued by the Joint Committee of the Board of Agriculture and Ministry of Food, calling attention to the prevalence of parasitic mange at the present time and the importance of the notification of the disease to the police by owners of animals. By an amendment introduced this year to the Order of 1911 an animal affected with mange may still be worked subject to certain conditions, but failure to notify involves a penalty of £20. Rules as to the prevention and cure of mange in horses are contained in Leaflet No. 8 issued free of charge by the Joint Committee, 6A, Dean's Yard, London, S.W.1. There is no doubt that parasitic mange has spread lately owing to the wide movement of horses, to indifferent care on the part of carters and horsemen, and to unhealthy nutrition in the horses themselves resulting from poor feeding. The revival of the rag and bone industry and the demand for small ponies may have been contributing factors. Since acariasis is communicable from animals to man precautions are necessary, especially to prevent men of the Army Veterinary Corps contracting scabies from the horse.

A "DROP-FOOT" SUPPORT.

Mr. C. H. Hough, medical officer in command of the Ethel Hedley Auxiliary Orthopædic Hospital, Calgarth Park, Windermere, calls our attention to an ingenious apparatus for supporting a "drop-foot," which is comfortable to wear and neat in appearance. The appliance consists of an anklet, made of leather or other material, which supports a spring attached to a metal loop which buckles round the instep. The spring which holds the instep band can be easily adjusted to any required position. The inventor is Mr. J. M. Sladen, Cleeve Howe, Windermere.

NECESSITOUS LADIES' HOLIDAY FUND.

THE war has reduced the incomes of many governesses, nurses, actresses, and other members of the poorer professional classes, which this Fund normally benefits. The Fund itself has suffered financially. A letter signed by the treasurer, Miss Constance Beerbohm, appeals for support in order to make a holiday possible for ladies unable to earn in the summer months. For those to whom a holiday is out of the question relief is supplied in the form of food, medicine, and clothing. The address of the treasurer is 48, Upper Berkeley-street, London, W. 1.

AN OVERWORKED MEDICAL MAN.

AN inquest was recently held at Camborne, Cornwall, relative to the death of a child who died before medical attendance could be procured. The medical witness stated that he was working from 12 to 16 hours daily; recently about one-third of the population of Camborne had been ill, and he was then sometimes employed for nearly the 24 hours. He added that it seemed absurd that Camborne, the largest town in Cornwall with a population of about 16,000, should have only two medical practitioners. The coroner suggested that the urban council should apply to the Army authorities for the release of an Army surgeon, and the jury endorsed the proposition.

The Lumleian Lectures
ON
CŒLIAC DISEASE.

BY G. F. STILL, M.A., M.D. CANTAB., F.R.C.P. LOND.,
PROFESSOR OF DISEASES OF CHILDREN, KING'S COLLEGE, LONDON; PHYSICIAN FOR DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE II.*

MR. PRESIDENT AND FELLOWS,—In my first lecture I described the clinical features of the condition to which the term "cœliac disease" has been applied, and as a working hypothesis I assumed that the syndrome of symptoms to which Gee gave the name is actually a specific entity. I propose now to consider its pathology, and at the outset I must crave indulgence for the speculative character of much that I have to say.

MORBID ANATOMY.

As evidence of specificity one naturally turns to morbid anatomy and to bacteriology, and, failing these, one seeks a specific cause in disturbance of function in some particular organ or organs. How far is it possible to demonstrate by such inquiry that in so-called "cœliac disease" we are dealing with a morbid entity due always and only to one specific cause?

I must first consider its morbid anatomy, and, unfortunately, the available records and observations are meagre in the extreme.

Dr. Gee himself, in his original paper on the subject, says: "Naked-eye examination of dead bodies throws no light upon the nature of cœliac affection. Nothing unnatural can be seen in the stomach, intestine, or other digestive organs. Whether atrophy of the glandular crypts of the intestines be ever or always present I cannot tell."

Dr. R. A. Gibbons, also, writing a year later (1889) than Dr. Gee, says: "Examination of the bowel after death has led to the discovery of nothing."

The only detailed record of a post-mortem examination which I have been able to find is that published by Drs. Poynton, Armstrong, and Nabarro (1913) in the Proceedings of the Royal Society of Medicine.

It refers to a boy who had had a prolonged attack of diarrhœa lasting eight months in the second year of his life, and again at five years began to suffer with diarrhœa which recurred at intervals until his death at the age of 9 years. The stools were at times of the pale, creamy, offensive character which suggests cœliac disease, the abdomen was much distended, and the boy much wasted. His weight at 8½ years was 27 lb. No record was kept of his height, but he was, as I remember—for he was under my care repeatedly at a convalescent home—much below the normal height for his age. Eventually an attack of vomiting, with severe abdominal pain, for which no cause could be found at autopsy, ended in collapse and death.

The noticeable features at post-mortem were thickening of the walls of the whole intestine both large and small, the mucosa of which shared in the thickening and showed also patches of acute congestion; the solitary follicles were prominent in the large intestine, Peyer's patches in the small were not enlarged, the stomach wall and mucosa showed similar thickening and congestion.

The liver was large, pale, and soft, and showed marked fatty change. There was no obvious naked-eye alteration in the pancreas; there was no tuberculosis anywhere.

Microscopic examination showed much small round-cell infiltration of the mucosa and submucosa, but more in the stomach and small intestine than in the large bowel. In places there were small blood extravasations in the mucosa. The liver showed fatty degeneration. The pancreas showed "marked increase in the interlobular fibrous tissue, particularly that surrounding the ducts," indicating, it was thought, some interlobular pancreatitis.

In connexion with this case I will mention one which showed post-mortem appearances so closely similar that they point almost certainly to the same condition.

Clinically the diagnosis had been in question on account of the unusually rapid course and also the comparatively late age at which the symptoms began. A boy aged 7 years was under my care 19 weeks with looseness of the bowels, amounting at times to actual diarrhœa. He had been sent into hospital as a case of tubercular peritonitis on account of wasting and enlargement of the abdomen, but one early began to doubt this diagnosis, for the stools at times were suggestive of cœliac disease, and, moreover, there was, with œdema and purpura, frequently recurring tetany.

Examination of the stools showed no dysentery bacillus, but a large predominance of a bacillus which could not be exactly identified but resembled in many respects the *Bacillus lactis aerogenes*. On the ground that the case was probably one of cœliac disease the boy, after several weeks of unsuccessful treatment, was put upon a fat-free diet and at once improved greatly, as cœliac cases usually do upon such feeding, but a few weeks later had a relapse of looseness with much distension of the bowel, and died of exhaustion.

At post-mortem there was about half a pint of serum in the abdomen and the bowels presented a remarkable appearance; they were of a dark slaty colour externally, and looked, and were, thickened throughout; the stomach did not show this appearance. On opening the bowel the mucosa was seen to have a swollen and congested appearance throughout, but there was no ulceration.

The liver weighed 19 oz. in spite of being considerably congested; the normal average weight at this age is 23·6 oz., so that the findings in this case confirmed the results of clinical examination by percussion, to which I drew attention in my previous lecture. The pancreas weighed 1 oz. and showed nothing abnormal to the naked eye. There was no tubercle anywhere.

Microscopic examination of the duodenum, ileum, and colon showed much small round-cell infiltration of the mucosa and submucosa, and this was most marked in the duodenum. The liver showed engorgement with blood, but otherwise nothing abnormal. The pancreas showed some excess of fibrous tissue, especially around the ducts, the appearance being suggestive of some pancreatitis.

There was thus, except in the absence in this case of fatty change in the liver, a close agreement in the post-mortem findings in these two cases. Unfortunately scrapings were not taken from the mucosa of the bowel, so that its bacteriology remains doubtful.

It is clear that in these two cases there was an inflammation involving the whole intestinal tract, an inflammation obvious to the naked eye as well as to microscopic examination; moreover, the marked thickening of the wall of the bowel was something quite unusual.

I have examined large numbers of children who have died of diarrhœa, in some cases of many weeks' or months' duration, and in many of very acute intensity, but these ordinary cases of gastro-enteritis or ileocolitis show no such thickening of the bowel; often, indeed, the wall looks rather thinner than normal, as if it were wasted.

I lay stress on this point because it suggests that the inflammatory change was, at any rate, not merely a terminal occurrence; it had probably existed a considerable time, possibly months. On the other hand, it would not be safe to conclude that this was necessarily a primary manifestation, or, indeed, even an essential part of the disease; it is, at least, conceivable that the whole inflammatory process might be secondary to some functional failure of digestive secretions, with resulting abnormal decomposition of food residue favouring the growth of harmful bacteria, and so producing an inflammation entirely secondary in character in the wall of the intestine.

In this connexion I would recall the clinical observation which I mentioned in my previous lecture, that the character of the stools tends to change as the disease progresses.

The pale, porridge-like, rancid stools which are a feature of the earlier stage are often replaced after several months by darker brownish stools with much mucus, perhaps even a little blood, and with an odour offensive enough, but no longer typically rancid. In other words, the stools, which at first were compatible with a fault of digestion alone, at a later stage show clear evidence of inflammatory change in the bowel.

The same difficulty arises in regard to the changes found in the pancreas—Are they primary or secondary?

It is tempting to think of them as primary, as then it would be easy to explain the early occurrence of the pale fatty stools; but again the possibility, if not the probability, must be admitted that the increase of fibrous tissue, the pancreatitis if it be so, may be merely secondary.

BACTERIOLOGY.

If the morbid anatomy, so far as it has been observed, affords no reliable clue to the specific cause of this affection, it gives at least ground for conjecture that some specific bacterial agent may explain the appearances described in the bowel, and though, as I have suggested, these may be secondary rather than primary, the finding of an organism constantly, even where these secondary changes had already occurred, would be presumptive evidence that the organism found was the primary cause of the disease; at any rate, it would give good ground for seeking further evidence of its specificity.

The earliest observations of which I am aware are those by Herter (1908). He studied the fæces of these cases, which he called "intestinal infantilism," and considered that the most noticeable feature was the predominance of Gram-positive organisms. Two, in particular, he considered to be sufficiently constant and predominant to justify the suggestion that they may be causal—namely, a bacillus which he called *Bacillus infantilis* and the *Bacillus bifidus*. Both, however, are by his own admission found in the stools of healthy nurslings, and some observers have found the *B. bifidus* to be common in the normal stool at this age, and have found both of them also in ordinary cases of infantile diarrhœa.

It is therefore clear that neither of these is specific in the sense that its presence is evidence of the disease, nor even in the sense that if it becomes pathogenic at all it will produce this particular symptom-complex. Indeed, the only evidence of pathogenicity mentioned by Dr. Herter in the case of *B. infantilis* is the experiment on a dog which was fed on milk first sterilised and then inoculated with *B. infantilis*. The animal developed a persistent diarrhœa, which ceased only with the discontinuation of the *B. infantilis* milk. A second trial gave a similar result. Injected into guinea pigs, neither *B. bifidus* nor *B. infantilis* showed any pathogenicity.

In addition to these organisms various cocci were found in the stools, but no causal influence is claimed for them.

As confirming the pathogenic rôle of the *B. infantilis* and the *B. bifidus*, Dr. Herter points out that these organisms become less and less noticeable in the stools as the child improves, when such organisms as *B. coli* and *B. lactis aerogenes*, Gram-negative forms, take their place.

*Lecture I. was published in THE LANCET of August 10th, 1918, p. 163.

With these observations are to be contrasted those recorded by Drs. Poynton, Armstrong, and Nabarro in the paper already mentioned.

In their fatal case the stools were examined during life. It is to be noted that the boy was 8½ years old and had been suffering from this affection at least 3½ years when the stools were first examined bacteriologically; they showed predominance of Gram-negative bacilli, some Gram-positive diphtheroid bacilli, and Gram-positive micrococci. Plate cultures showed only Gram-negative bacilli in abundance, and subcultures gave most of the reactions typical of the *B. coli* group. At the autopsy scrapings of the mucosa from the large intestine were used to make cultures on neutral-red agar plates. Coliform and streptococcal colonies were found, but the organism to which special attention was directed proved to be a dysentery bacillus of the Flexner type modified, a Gram-negative bacillus agglutinating with a *B. dysenteriæ Y* agglutinating serum up to 1 in 2000.

In another of their cases bacteriological examination of the stool showed no dysentery bacilli; there were many Gram-negative bacilli and a few Gram-positive streptococci; in this case no opportunity occurred for taking scrapings from the intestinal mucosa.

Bacteriological investigations, for which I am indebted chiefly to Dr. D. N. Nabarro and to Dr. W. d'Este Emery, were made in 11 of my cases.

In three of these the stools only were examined and the dysentery bacillus was isolated from one, a girl aged 2 years, in whom the disease had lasted five months.

In six an agglutination test, as well as a bacteriological examination of the stools, was done, and in four of these the agglutination test gave a positive result with one or more strains of dysentery bacillus (in three almost equally strongly with the Flexner, Shiga, and Y strains); in one of these four a dysentery bacillus of the Flexner type was found in the stools; in two of the six cases where the double investigation was made both agglutination and fæcal examinations were negative as regards the dysentery bacillus. In two cases the agglutination test only was used; one was strongly positive for the Flexner and Y strains of dysentery bacilli and only less strong for the Shiga, the other was negative for all these. These results are shown in the accompanying table:—

Dysentery Bacillus in Cœliac Disease.

Case.	Agglutination test.			Fæces.
	Flexner.	Shiga.	Y	
1	Strong.	Strong.	Strong.	Negative.
2	"	"	"	"
3	Negative.	Negative.	Negative.	—
4	"	"	"	Negative.
5	Strong.	Partial.	Strong.	—
6	—	—	—	Positive.
7	—	—	—	Negative.
8	Partial.	—	Strong.	Positive.
9	—	—	Partial.	Negative.
10	—	—	—	"
11	Negative.	Negative.	Negative.	"

It will be seen, therefore, that out of the 11 cases no less than 6 gave evidence of infection with a dysentery bacillus.

In the two cases in which the stools only were examined and no dysentery organism was isolated the findings were:

In the one, a boy aged 2 years, in whom the disease had been present three months, a predominance of Gram-positive organisms, especially *B. bifidus*, together with streptococci, *B. coli*, and pneumo-bacilli.

In the other, a girl who died at the age of 4 years, after suffering with this disease for nearly three years, the stool a few weeks before death showed Gram-negative organisms predominant, mostly *B. coli*, no dysentery bacillus nor other non-lactose fermenters, a few streptococci, *B. bifidus* in small numbers, whereas about six weeks earlier the Gram-positive organisms, chiefly bacilli, had predominated, and the *B. aerogenes capsulatus* had been present in large numbers; on that occasion, as later, the dysentery bacillus was not found.

The bacteriological findings, it must be admitted, are far from conclusive of any specific infective cause. The most suggestive part is the finding in some cases of a dysentery bacillus, and perhaps the more significance is to be attached to this inasmuch as the serum of some cases was found to agglutinate this bacillus.

The apportionment of pathogenic influence must always be difficult in the face of such a plethora of bacteria as is shown by investigations of the intestinal flora in any particular case or group of cases, but the observations are probably still less conclusive when they are limited to examination of the fæces. More reliable conclusions can be drawn from investigation of the mucosa itself or of scrapings taken from it. An example of this is the discrepancy mentioned in the case quoted above where examination of the stools during life showed no dysentery bacillus, whereas this was isolated in cultures from scrapings of the mucosa taken after death. Herter also found that the *B. bifidus* was much more numerous in the mucus immediately in contact with the mucosa than it was in the fæces. While, therefore, negative results in the bacteriology of the fæces have a certain value they must be received with caution, especially where, as in several of my own cases, only one or two examinations were made. For this reason the agglutination test may be regarded as more reliable.

I think, however, that one must be careful not to attach too much importance even to the agglutination test until much more numerous observations are available, and in particular until similar observations have been made upon cases in the early stages of the disease.

All the cases in which I have mentioned the finding of the dysentery bacillus in the stools, or a positive result for the dysentery organism with the agglutination test, have been cases of at least several months' duration, the earliest fully three months, and some as long as three years.

Before we can regard the dysentery organisms or any other as the specific cause of this affection it is necessary to exclude the possibility that their presence may be a mere epi-phenomenon.

Agglutination, no doubt, goes some way towards this; it proves that the presence of the particular organism concerned is exerting some pathogenic influence on its host, but this does not prove that it is the primary pathogenic influence. The growth and the predominance of this or that organism depends largely upon the soil, and probably there is no part of the body where the soil varies so much as in the intestine, but its variations in health are, so to speak, within fixed limits and dependent partly upon the character of the ingesta and partly upon digestive processes.

It is known that with temporary disturbances of digestion there are alterations, if not in kind, certainly in the relative proportions of the intestinal bacteria, and it is therefore conceivable that with profound and prolonged disturbance of digestive processes the soil may be so altered that an organism like the dysentery bacillus, which is now known to be much more widely disseminated than was thought a few years ago, might find a particularly favourable nidus and add its pathogenic effects to those of the primary digestive trouble.

I suggest this only as a possibility. There is clearly a strong probability that in some of the cases of cœliac disease, if not in all, there is a primary infective catarrh of the bowel, and that this is due, in some at least, to the dysentery bacillus.

FAILURE OF FAT ASSIMILATION.

I turn now to another question which calls for consideration in seeking for the primary and essential cause of this disease. Is it possible that the *fons et origo* is some profound digestive disturbance and not infective at all? As I. pointed out in describing the clinical symptoms, one of the most characteristic phenomena of cœliac disease is the pale stool, with appearance and smell suggestive of excess of fat.

As a homely method of demonstrating this, I have observed the sooty, spluttering flame when a match dipped in these fæces is set alight. Microscopically, also, it is evident in some of the stools by the large excess of fatty acid crystals, and sometimes by the obvious excess of fat globules, but the only certain gauge is quantitative chemical analysis.

According to Dr. Cammidge,[9] the normal range of variation on an ordinary mixed diet is 10–25 per cent. of fat in the stool, whereas in cœliac disease Herter found in one case (a boy, aged 8 years, in whom the disease had lasted five years) the total fat in the fæces amounted to 25–47·2 per cent. In one of Dr. Cheadle's cases the fat in the stools varied from 19·8 to 49·65 per cent., and in another was 33 per cent.

Dr. Cammidge has estimated the fat in three of my cases.

1. A girl, aged 5¾ years; duration of disease, 3¾ years; percentage of fat, 26·9.
2. Boy, aged 18 months; duration of disease, five months; percentage of fat 73·1.
3. Girl, aged 3 years; duration of disease, 12 months; percentage of fat, 42·5.

I have no figures from my own cases to show what proportion the fat passed in the fæces bears to the fat taken in the food—a very important practical point. Herter, however, investigating one of his cases, found that there was a loss of 20–25 per cent., and on one occasion even as much as 40 per cent. of the ingested fat. The normal loss in health varies from 2 to 8 per cent.; the average is 5 per cent.

Failure to absorb the fat of the food may be due to various causes, but traced to their sources these fall into two categories: (1) lack of preparation of the fat for absorption through deficiency of the fat-splitting function of the bile or of the pancreatic secretion; (2) failure of the intestinal surface to absorb, in spite of the fat being sufficiently prepared by the fat-splitting processes and saponification.

Question of Hepatic Insufficiency.

The pale colour of the stools led Dr. Cheadle to suppose that the deficiency was mainly one of bile.

Speaking (1903) of the stools in these cases, which he grouped under the heading acholia, he said: "They are obviously as destitute of bile as those of complete obstructive jaundice." More in accordance with recent observations is Dr. Gee's statement: "The paleness is commonly supposed to signify lack of bile, but the colour of fæces is a very rough measure of the quantity of bile poured into the duodenum, nay, more, stools are not always so wanting in bile as they seem to be, in particular opaque white food such as milk curd," (he might have added, "milk fat") "undigested, will hide the colour of much bile."

Certainly of any organic change in the liver there is no hint in this disorder.

Even in the most severe cases and in the most extreme stage there is no tendency to jaundice, nor has any change been observed post-mortem, except that in one of the cases quoted above the liver was fatty, but such a change is found, presumably as a terminal occurrence, in various conditions where it is certainly no essential part of the disease, for instance, with abdominal tuberculosis.

Analysis of the fæces, however, in two out of three of my own cases showed some deficiency of bile.

Indeed, in the one mentioned above, containing 73·1 per cent. of fat, there was only a trace of stercobilin and no biliverdin. In the other, containing 26·9 per cent. of fat, Dr. Cammidge notes "the reaction for stercobilin is not as well marked as in a normal stool." In both these cases it seems natural to suppose that deficiency of bile is responsible, in part at least, for the failure of fat absorption.

On the other hand, I must mention that in the third case, although there was 42·5 per cent. of fat in the stool, there was no apparent diminution of stercobilin (incidentally, it is noteworthy that the colour of the stool in this case was nearly as pale as porridge, showing that the colour alone is little gauge of the activity of the liver). The deficiency of stercobilin in these cases has been noted also by Dr. Hutchison,[10] but he points out that there is no other evidence of hepatic insufficiency, in particular the urea secretion attains its normal level.

In connexion with this question of hepatic insufficiency I would recall the observations mentioned in my previous lecture showing that the liver dullness in cœliac disease is usually smaller than normal. I know not whether there is any connexion between the smallness of size and the deficiency of secretion, but it is, at least, a curious coincidence.

On the whole, there seems to be evidence that one of the fat-splitting agents, the biliary secretion, is deficient, at least in some cases. I shall consider later how far this is responsible for the failure of fat absorption.

Question of Pancreatic Insufficiency.

The chief agent in the preparation of fat for digestion being the pancreas some fault in this gland or its function has naturally been suspected.

Dr. Gibbons (1889) suggested that cœliac disease might be due to some profound inhibition of the functions of the pancreas. The combination of symptoms also, chronic looseness of bowels with arrest of growth, recalls the cases which Dr. Byrom Bramwell[11] described as "pancreatic infantilism."

But is there any satisfactory evidence of pancreatic insufficiency in these cases of cœliac disease?

Approaching the question first from the clinical side I tried in three cases Sahli's test, administering iodoform in glutoid capsules to see if the capsule, insoluble by the gastric juice, had been dissolved by the pancreatic secretion, so that the drug could be detected in the urine within a few hours after administration. In one only of the three this reaction—i.e., the failure of the drug to appear in the urine—indicated deficiency of pancreatic secretion.

I also tried Loewi's test, dropping adrenalin solution into one eye and taking dilatation of the pupil on that side as an indication of pancreatic insufficiency. In four cases out of six there was no dilatation of the pupil, in two there was slight but quite definite dilatation, and one of these was the case in which Sahli's test was also positive, in the other the Sahli's test was not used.

The microscopic investigation for azotorrhœa, as it has been called—in other words, failure of digestion of muscle fibres, which has been regarded as evidence of imperfect pancreatic digestion—gave negative results in five cases examined.

In five cases the amylase content of the urine was investigated on the lines directed by Dr. Percy Stocks.[12]

In the absence of any sufficient data for children of this age the normality or abnormality of the results could only be judged by applying the same method to control cases of approximately the same age. This was done, and it was found that on the whole there was remarkably little variation amongst the controls, 10 units was the number found in three cases, 6·6 in one, and 20 units in two cases, whilst of cœliac cases one showed 13·3 units, another 10, another 20, and another 6·7, so that in none was there an increase of amylase such as is supposed to indicate affection of the pancreas.

Whether the amylase content of the urine is a reliable index of the sufficiency of the pancreas has yet to be proved. It is difficult to believe that the amount of amylase in the urine can be a safe indication of the efficiency of the pancreas unless the diet is taken into account, for Pavlov has shown how profoundly the ferments of the pancreatic juice can be influenced experimentally by diet.

To sum up the result of my clinical investigations of the pancreatic function in these few cases, there were indications in some that it was defective, but in the majority all the tests applied proved negative.

So far, therefore, as these tests have any weight, the balance of evidence is against any pancreatic insufficiency as a constant or essential factor in the disorder.

There is another clinical observation which may point in the same direction—namely, the failure, at any rate in my hands, of pancreatic extract in treatment, a point of contrast between these cases and the "pancreatic infantilism" in which Dr. Bramwell obtained such rapid and remarkable improvement with preparations of pancreas.

Laboratory investigation of the stools gives but little support to the idea of pancreatic insufficiency.

Indeed, in the three cases in which Dr. Cammidge examined the stools for me, the trypsin index in each was rather unusually high, suggesting that there was even abnormal activity in that gland. In two of these Dr. Cammidge thought that the excess of trypsin was so considerable as to point to some active inflammatory change in the pancreas, an interesting suggestion in view of the post-mortem finding in the cases I have quoted.

Further evidence of pancreatic activity is the character of the fat passed in the stools. Herter's observations showed that the greater parts of the fats lost are in the form of fatty acid, and that the sum of the fatty acids and the soaps make up, on the average, about three-quarters of the fat lost. These results, compared with the normal averages found by Dr. Cammidge (1 per cent. of neutral fat to 20 per cent. of fatty acids and soaps), show a proportion of neutral or unsplit fat which would not be inconsistent with some slight degree of pancreatic insufficiency.

Even this, however, is negatived by the finding in my three cases already mentioned, where the proportion of split fat in the stool was much higher, varying from 25·9 per cent. to 72·1 per cent., as against only 1 per cent. of neutral fat. The percentages will be best seen from the accompanying table, in which the normal is given for comparison:—

—	Total fat.	Neutral fat.	Fatty acids.	Soaps.
Case 1	26·9	1·0	14·6	11·3
Case 2	73·1	1·0	33·8	38·3
Case 3	42·5	1·0	30·1	11·4
Normal, on mixed diet (Cammidge)	21·0	1·0	9·0	11·0

It is evident from these figures that there is no failure in the splitting of fats, and if one assumes that the pancreatic secretion plays the chief part in fat-splitting the idea of any "profound inhibition of the function of the pancreas" is clearly untenable.

Failure of Fat-absorbing Power of Intestinal Mucosa.

It would seem, then, that, although in individual cases the biliary secretion may be found deficient, there is no interference with the fat-splitting process which prepares fat for absorption, and therefore we must conclude that the fault lies in failure of the absorptive function of the intestinal mucosa. Is this a functional failure or is it due to organic change in the intestinal mucosa?

If we could assume as the primary factor in cœliac disease a functional failure of the fat-absorbing power of the intestines, this would account for many of the features of the disease, for, as I have already pointed out, the excess of unabsorbed fat in the stools favours putrefactive changes which in themselves probably render the stool irritating to the bowel and so would account for the looseness of the bowels; moreover, with putrefactive changes there would be alteration in the character of the intestinal flora, and probably conditions favourable to the growth of pathogenic organisms, so that, as a secondary phenomenon, inflammatory lesions would occur.

But apart from the difficulty of proving that purely functional failure of intestinal absorption ever occurs, there is such definite clinical evidence in a certain proportion of cases of cœliac disease that some catarrhal or inflammatory condition is an early, if not the earliest, pathological change that is seems a more probable view that even in the cases which appear to begin quite insidiously there is some degree of catarrh, for these, like the others which start with definite diarrhœa, show before long more or less of the typical recurrent looseness of the bowels.

Gee evidently suspected that there was some organic change in the intestinal mucosa, for he hints, as I have mentioned, "atrophy of the glandular crypts in the intestine," but even in the fatal cases which I have described, in which the disease had lasted in the one five months and in the other at least four years, microscopical examination showed no such atrophy. On the other hand, definite acute inflammatory infiltration was found, but it is extremely doubtful whether the appearances were consistent with inflammation which had lasted years, as it must have done if it is to acconnt for the non-absorption of fat, which is one of the earliest symptoms of cœliac disease.

Moreover, it is difficult to reconcile the presence of an acute inflammation as an essential factor in the disease with the observations of Dr. Gee that the bowel showed nothing abnormal in his case. The clinical facts also are opposed to any acute inflammatory condition as an essential factor, for sometimes the onset is quite insidious and without diarrhœa; on the other hand, the symptoms in the later stages of the cases which do badly, the passing of much mucus and sometimes blood, point unmistakably to some acute irritation, probably inflammatory process, in the bowel.

The first step in the disease may well be a catarrhal condition of the mucosa in the small intestine, where in health the absorption of fat occurs chiefly or entirely.

I suppose it is conceivable that such a catarrh, due to bacterial irritation, might eventually, especially with the constant irritation due to putrefactive change in the unabsorbed fat, become more acute or be altered in character by the supervention or predominance of some particular organism—e.g., the dysentery bacillus.

But though it is agreed that catarrh of the small intestine may interfere with the absorption of fat, it is difficult to see why, if this explanation be the correct one, the failure of fat-absorption should be so much more pronounced a feature in cœliac disease than in other diarrhœal conditions where catarrh of the upper part of the whole of the bowel occurs—for instance, the common summer diarrhœa or other forms of gastro-enteritis.

WASSERMANN REACTION.

In the search for a specific cause of cœliac disease the possibility of congenital syphilis had hardly presented itself to my mind, so conspicuously absent had been all the usual symptoms of such infection.

In the light, however, of recent experience showing how slight or equivocal may be the clinical evidence where a Wassermann test is found to be positive—and one must add that in some such cases, but by no means in all, the diagnosis of syphilis is confirmed by the results of treatment—it seemed advisable to apply this test to cases of cœliac disease. This was done in six cases; in three out of the six the reaction was positive.

It would be out of place here to enter into any general consideration of the significance to be attached to a positive Wassermann reaction obtained where all other evidence of congenital syphilis is lacking, but at the risk of being held guilty of heresy I will venture to say that in my opinion a positive Wassermann reaction, extremely valuable as it is as confirmatory evidence, is not by itself proof of congenital syphilis.

These cases of cœliac disease in which the test was positive were none of them in any way suggestive of congenital syphilis so far as family history or the child's own past history was concerned, nor on examination was there any symptom of congenital syphilis, unless the cœliac disease itself was to be regarded as such. Treatment with mercury in one case, so far from doing any good, seemed rather to hinder improvement; at any rate, the child began to improve directly it was stopped; in another it seemed to have no effect at all.

There seemed, in fact, so little to warrant accepting the reaction as proof of congenital syphilis that we sought corroboration in testing the parents and other members of the family.

In one severe case of cœliac disease, a girl aged 3 years and 5 months, the Wassermann reaction was done twice and was on each occasion strongly positive; the mother and the father were both definitely negative.

Another case, a girl aged 5½ years with moderately severe cœliac disease and showing, as did the previous case, very marked arrest of growth, gave a definite positive Wassermann reaction; her mother gave a negative; the father was abroad and could not be tested.

The third case, a girl aged 5 years and 4 months, a milder case of cœliac disease but showing arrested growth, gave a positive reaction; the father was not available for testing, but the mother and also the sister, 15 months younger than the patient, were both entirely negative.

In none of these cases had the relatives who were tested had any treatment for syphilis so far as was known.

I leave those who consider a positive Wassermann reaction to be *per se* proof of congenital syphilis to explain such cases with what ingenuity they may.

These findings seem to me rather to emphasise the uncertainty of significance attaching to this reaction where there is no other reason to suspect syphilis, and to support the view that there are other conditions beside syphilis which may give a positive result with this test.

TOXIC ABSORPTION.

I shall turn now from the unanswered, and at present unanswerable, questions of pathogeny which I have raised to a consideration from the pathological standpoint of some of the clinical phenomena of cœliac disease. One of the noticeable symptoms, especially in severe cases, is dropsy occurring chiefly in the distal parts of the limbs and also the face, and sometimes associated with ascites.

This is common enough in any prolonged diarrhœa in infancy and, indeed, with any condition of extreme wasting. As it occurs most commonly in advanced stages of disease it is apt to be regarded as chiefly, if not altogether, an evidence of failing circulation, with, perhaps, some hydræmia as a contributory cause.

Without denying that these may play some part, as also may the diminished urinary secretion in diarrhœa with the resulting retention of chlorides, I would point out that there may be another factor, and that the œdema which occurs in cœliac disease may well be determined by it—namely, toxic absorption from the intestine.

Apart from the fact that no particular substance having this effect has been isolated from the intestine or its contents, it may be objected that in cœliac disease wasting and feebleness are usually pronounced, and that therefore there is no reason for seeking further for a cause; at any rate, such a view would require support from cases in which these recognised causes are absent.

There are at least two groups of cases which seem to me to corroborate this suggestion.

First, a very common one in which there is puffiness of the eyelids, especially of the lower eyelid, accompanying chronic constipation or chronic indigestion; this surely is œdema at its vanishing point, or rather its first appearing point. I have thought that among the children brought to one for minor ailments one could often pick out those with chronic intestinal disorder, especially affecting the lower bowel, by this puffiness of the lower eyelids.

The second group of cases, in which clinical association and sequence seem to point to a similar connexion, is a rare condition of general œdema with no albumin in the urine and no evidence of organic disease. Puzzling cases are these, and various are the explanations which have been offered. I am not referring to those in which such a condition follows scarlet fever and is associated with diminution in the secretion of urine without albuminuria, but to children in whom there has been no recent illness, and the general œdema apparently stands by itself, an unexplained phenomenon. In some of these the stools are found to be extremely fœtid and offensive although there is no diarrhœa, rather indeed the reverse; therewith the urine may or may not be diminished in quantity.

An instance of this was a boy, aged 11, who a week before coming under observation was noticed to be puffy in the face, and three days later his legs were swollen; the bowels were open three or four times a day, and the stools were extremely offensive. There was some fluid in the abdomen and general dropsy. The urine contained no albumin, it was high coloured, and rather scanty. The boy was kept under observation, and the outstanding feature, apart from the œdema, was the foul fœtor of the stools.

I can offer no proof that the œdema in such a case is due to toxic absorption from the bowel, but the association suggests it.

How far the œdema which accompanies such a condition as ileo-colitis and prolonged failure of digestion is due to such absorption and how far to the wasting and exhaustion is, I think, open to question, but there is much to suggest that in some of these also the œdema is determined largely by the unwholesome character of the stools. I have particularly noticed that in some wasted infants the appearance and disappearance of œdema corresponded closely with variations in the degree of unwholesomeness of the stools, and seemed to be much more influenced by this than by the number of the stools.

This observation certainly applies to cases of cœliac disease, in which, therefore, I would suggest that œdema is to be regarded as due, in part perhaps to feeble circulation and hydræmia, but in part at least to toxic absorption from the bowel.

Certainly the œdema is not necessarily terminal. I have known it to occur in several cases quite early in the disease, and in those that recovered as well as in those that died.

Another symptom which is worthy of consideration in this connexion is purpura.

This, like œdema, is common enough as a late symptom of many diseases which end with emaciation and exhaustion, but it is particularly noticeable that in cœliac disease purpura is sometimes a recurring symptom for years.

For instance, in a girl who died at the age of 9½ years after suffering with cœliac disease from the age of 20 months, bruise-like patches of purpura appeared on many occasions from the age of 2½ years up to the time of her death, although during the greater part of this time she was well enough to be up and about.

In another case, a boy, aged 7¼, in whom the disease had been present for five years, but who was still well enough to get up and walk about, patches of purpura occurred from time to time, and noticeably in relation to unhealthiness of the stool; when the stools improved and became more normal the purpura would cease to appear, then a particularly unhealthy stool, without diarrhœa, would be associated with a fresh patch or two of purpura.

I would lay some stress upon the fact that often, so far from there being any increase of frequency of stools, there has often been a noticeable decrease in their frequency, perhaps no stools at all for 24 hours, just before the purpura appears. The non-frequency of stools may be more than a coincidence; delay in the evacuations of the unhealthy fæces may be a determining cause of the absorption which results in purpura.

But, even if this view be correct, the particular substance which causes the purpura is still to seek.

Mere constipation, even when most chronic and severe, does not cause purpura, although there may be various symptoms suggestive of toxic absorption, headache, lassitude, sallow skin, and so forth; it is probable, therefore, that the cause is to be sought either in the products of particular bacteria or in the chemical products of intestinal putrefaction, and only when these hypothetical substances are present does absorption from the intestine produce purpura.

It has been suggested that indol may be the poison in question; and when indol is being formed in large quantities in the bowel this is indicated by a marked indican reaction in the urine. It has been specially noticed that in many cases of purpura a marked indicanuria is present; in one of my cases of cœliac disease I found a very definite indican reaction during the eruption of purpura, and this reaction became much less, in fact, almost entirely absent, when the purpura ceased to appear.

Apart from œdema and purpura, the occurrence of tetany in cœliac disease probably points to toxic absorption.

Here, at any rate, the question of cause is not complicated by any likelihood of production by feebleness or failing circulation; the tetany may, as in one of my cases of cœliac disease, recur for years, and that when the patient is well enough to be up and about.

It is true that tetany has been attributed to deficiency of calcium salts in the blood; and in cœliac disease there is an obvious reason for excessive loss of calcium. Quite apart from the question of tetany, this drainage of calcium was emphasised by Dr. Herter in connexion with the amount of split fat in the form of soap passed in the fæces. In one case he found that in ten days a boy aged 8 years lost 1·07 g. of calcium oxide in 198 g. of soap in the fæces, and such a loss, though it may sound very small compared with the intake of calcium in the food, is really large in relation to the very small proportion of the food-calcium which can be absorbed in health.

But does this satisfactorily explain the tetany?

I think not. If it were so, one would certainly expect that the occurrence of tetany should correspond more or less closely with the periods when the fatty character of the stools is most in evidence. I have no analytical evidence that the early pale, rancid, obviously fatty stools contain more fat than the later brown slimy or shreddy stools in which excess of fat, if present at all, is certainly not obvious; but if one may assume this, as I think one fairly may, then there is no such correspondence between the tetany and the fatty stools; indeed, the reverse is the case, for tetany is not an early symptom in cœliac disease, it occurs after the disease has been present for a long time and usually when the stools, though extremely offensive, have lost the characteristic fatty appearance of the early stage.

Absorption of some toxic material from the bowel seems much more in harmony with the clinical fact.

ARREST OF GROWTH.

From these questions of toxic absorption I pass to the consideration of one of the most striking phenomena of cœliac disease, the arrest of growth.

Why do these children fail to grow? It is easy to reply vaguely that the cause is the general failure of nutrition, but such an answer is inadequate. It is unfortunate that much that has been written on the problems of growth entirely ignores the fact that increase of weight and length do not necessarily go *pari passu*, and that experimental evidence as to the one is not necessarily applicable to the other. A physiological illustration of this must be recognised by any one who measures many children at the growing age; a rapid increase in height is not associated usually with increase in weight, often, indeed,

with a marked decrease, and the child may be visibly thinner; this is very noticeable in infants and gives rise to much needless anxiety, though I have not seen it mentioned in a single text-book that an infant in perfect health will often cease to gain or will actually lose weight when it is growing rapidly in length.

In disease, also, there is no necessary correlation between the growth in length and the state of general nutrition as shown by the weight. As I have mentioned already a marasmic infant may grow steadily in length, and a child may become tall whilst wasted with chronic tubercular disease.

It would seem, therefore, on grounds of analogy that there is no justification for assuming that the remarkable arrest of growth in length in cœliac disease is a necessary corollary of the arrest of growth in weight, and, while it seems only reasonable to assume that both may be related in some degree—though not necessarily in the same degree—to the general failure of nutrition, the failure of growth in length is so much more pronounced in cœliac disease than in most other conditions of disturbed nutrition that we may well seek for some special cause.

Amongst the various possibilities which present themselves there is one which, I think, ought to be considered—namely, that deficiency of fat absorption may be sufficient cause for arrest of growth.

This suggestion has the support of experimental evidence; young rats fed on a diet of lean horseflesh, so that there was hardly any fat given, became stunted in growth, even though apparently in good health; with a diet exclusively of oxflesh, which, though still affording them too little fat, contains more than does horseflesh, the rats throve better, but their growth was still retarded to some extent. (Watson and Hunter.[13])

If the failure of fat assimilation be the cause of the failure of growth this would bring cœliac disease into line with Byrom Bramwell's pancreatic infantilism, where arrest of growth was associated with the passage of fatty stools and where improvement of fat absorption by administration of pancreatic extract, with consequent disappearance of the fatty character of the stools, was followed by rapid growth.

It is not apparent, however, how deficiency of fat in the diet has any special influence in arresting growth.

If the absorption of calcium is dependent to any considerable extent upon the splitting of fat and combination with the fatty acids thus set free, and if deficient absorption of calcium inhibits growth then the order of events is easy to understand. As I have already pointed out, Herter has already shown that there is an appreciable loss of calcium with the soaped fat passed in the stools of cœliac disease. Clearly the same result would come also from any considerable failure of fat splitting or saponification.

I have mentioned a case in which remarkable bending of the bones began at the age of 8 years, after the cœliac disease had been present nearly five years, and the child had been kept for four years on a diet containing a minimum of fat; an occurrence strongly suggestive of calcium deficiency.

I have shown, also, that there is very striking delay of ossification of epiphyses, which may indicate a deficiency of calcium, but, granted this deficiency, is it adequate cause for the striking arrest of growth in cœliac disease? I have shown in my previous lecture that growth in height shows no necessary relation to the date of commencement, nor to the stage of advancement of ossification in epiphyses.

That relative deficiency of calcium and rapid growth are by no means inconsistent is shown by what happens in cretins when thyroid treatment is begun at the age when walking has recently been acquired, the child begins to grow rapidly and at the same time if the child is allowed to run about much, the previously straight legs become bowed and bandy, presumably from deferred calcification of the rapidly growing bone.

The disease which might have been expected to throw most light upon this point is rickets.

There is strong evidence that fat deficiency in the diet is a large factor, perhaps the determining factor, in the causation of rickets; moreover, there is clear evidence of deficient calcium deposit in the rachitic bone. Here, then, we seem at first sight to have the required link bringing the fat absorption into direct relation with formation of bone.

But if this view of the pathogeny of rickets is correct we are faced by another difficulty in regard to cœliac disease—it should be associated closely with rickets; whereas one of the very striking facts which I have already mentioned in connexion with its symptomatology is the entire absence of rickets in most cases. Conversely also, if the failure of fat absorption be the cause of the stunting in cœliac disease, arrest of growth might be expected far more commonly than it occurs in rickets.

The problem is evidently a complicated one, and it is not rendered less so by a comparison with such a condition as the congenital steatorrhœa described by Garrod and Hurley,[14] in which the passage of 80 per cent. of fat in the fæces, amounting to a loss of 25 per cent. of the fat intake, was associated neither with arrest of growth nor with rickets.

THE LATE JOHN ST. CLAIR BOYD, M.D. R.U.I.—Dr. John St. Clair Boyd, the well-known Belfast surgeon, who died suddenly of cardiac disease, was a graduate of Queen's College, Belfast. After further study at Edinburgh and Paris he became an assistant to Mr. Lawson Tait in Birmingham when that well-known surgeon was at the height of his career. Returning to Belfast, he was appointed surgeon to the Samaritan Hospital, but ill-health obliged him to retire about ten years ago. He was also consulting gynæcologist to the Ulster Hospital for Women. Dr. Boyd was a man of literary taste and well versed in the study of the Irish language. He married a daughter of the late Dr. Stevenson Macadam, lecturer on chemistry in the Edinburgh Extra-Mural School.

THE TREATMENT OF CASES OF SHELL SHOCK IN AN ADVANCED NEUROLOGICAL CENTRE.

BY WILLIAM BROWN, M.A., M.D. OXON., D.SC. LOND.,

READER IN PSYCHOLOGY IN THE UNIVERSITY OF LONDON, KING'S COLLEGE; O.C. CRAIGLOCKHART WAR HOSPITAL.

WHILE in charge of an advanced neurological centre in France during the period November, 1916—February, 1918, I have had to deal with between two and three thousand cases of psychoneurosis (neurasthenia, hysteria, and psychasthenia), and in the following paragraphs I will endeavour to give, in broad outline, a general view of the methods of treatment which have seemed to be most useful, and a statement of certain statistical results. The great majority of cases came under my care within 48 hours of their breakdown, and I was able to return 70 per cent. of them to the line after an average of a fortnight's rest and treatment in hospital; of course, certain individual cases needed a longer rest in hospital, up to two or three months. I feel sure that this success was due more often to *prevention* than to cure. By seeing so many of these light cases so early I was able to *prevent* the development of further hysterical or pithiatic symptoms which would otherwise have taken place.

Essential Factors in Causation and Treatment.

It is important that the patient should have the benefit of a thorough examination of his nervous system at the earliest possible moment after the shock of the shell explosion. The incipient functional symptoms from which he is suffering make him fear, vaguely or definitely, that he has sustained some organic injury of the nervous system. This fear encourages the further development of such symptoms. It and its effects can be brought to an end by the reassuring remarks of the neurologist, after he has completed his examination. But those remarks must be repeated and forced upon the patient's notice. Especially is it the note of certainty in the doctor's voice which carries conviction. By one means or another the patient must be completely convinced of the truth of the doctor's explanation of his symptoms, and of the promise that they will quickly disappear. This conviction must pass beyond the stage of mere intellectual awareness and acceptance, and acquire the dynamism of strong emotion. Enthusiastic expectation of a rapid recovery is another essential condition of success, just as it was an earlier apprehension which was responsible for the development of the symptoms.

This is more than mere suggestion and counter-suggestion. The mechanical processes of auto- and hetero-suggestion do certainly come into play in the *fixation* of the symptoms and in their later development and multiplication. But the *origin* of the symptoms (tremors, difficulties of speech and locomotion, profuse sweating, headaches, diminution or loss of various forms of sensation, &c.) is to be found in the intense emotion of fear caused by the shell explosion, of which they are the objective physical manifestations. In like manner, although counter-suggestion plays its part in the cure of these functional symptoms, the factors which are of very much greater efficacy and importance in bringing about a *permanent* cure are: (1) persuasion, whereby the patient is rationally convinced of the true nature of his symptoms; and (2) the sthenic emotions of confidence, conviction, and expectation, which have a unifying effect upon the mind, and counteract the disintegrating effect of mechanical suggestion.

It will thus be seen that I adhere to Déjerine's theory of the pathogeny of the psychoneuroses in preference to that of Babinski. As regards the "period of meditation" which often elapses between the occurence of the emotional shock and the onset of the earliest symptoms, I would also follow Déjerine in holding that it is a period of subconscious emotional development. Babinski and his followers believe that it is a period during which auto- and hetero-suggestion coöperate to bring about the ultimate outbreak of the symptoms. The original shock, no doubt, produces some weakening of mental synthesis, although outwardly the patient does not appear greatly disturbed. The appropriate

emotional reaction, with its innervations and external manifestations, develops gradually during the following few hours or days, as the patient's intellectual awareness of the accident arouses by association earlier emotional memories. The symptoms that eventually arise are such emotional manifestations in a state of relative dissociation and permanence. As Déjerine says:—

"Everything that an emotion may create in an accidental and transient way hysteria may accomplish in a lasting way."[1]

Case of Delayed Onset of Symptoms.

I have several examples of this delayed onset of symptoms in the case of hysterical mutism and hysterical hemiplegia which I hope to analyse and describe on another occasion. But I have obtained the following unbiased introspective description from one of my officer patients who suffered from hysterical spasmodic contractions of the abdominal and leg muscles and profuse sweating and tachycardia, which came on some days after the time when he was exposed to heavy shelling. His account is as follows:—

"My feelings during the shelling are hard to define, as I was too fully occupied to allow for much thought on the subject. Owing to the small area to which we were confined, there was no opportunity of being able to give vent to the pent-up feelings that were in me, and in consequence my nerves were strung up to such a pitch that I felt that something in me would snap. Every shell fired seemed to be nearer the mark than the last, and the ground all around was covered with shell holes. The general feeling was that 'the next one' would land right in the post. Part of the trench had already been blown in. The back blast from each explosion flattened us up against the wall of the trench.

The days following I was always thinking of this episode, and nights I could never sleep, but would just doze and then wake up with a start, with my heart palpitating furiously and with great difficulty in breathing. I would also find myself in a profuse cold sweat, especially of the scalp, forehead, and hands. Then my legs began to be affected and would shake as though I had the ague. This would come on in the day at times, but invariably happened at night when I was lying down. About 10 days later I was troubled with my stomach [he means abdomen]; at night something—I suppose my nerves—started pulling me up forward as I lay down and my body shook all over. This would happen every two or three minutes. This action affected my back, and I had a belt of pain around me. During this time I was always troubled with my heart, and I found it hard to lie down at all. The cold sweats also continued."

Emotional Origin of the Symptoms.

This description, written by an officer unversed in psychology and quite ignorant of the question at issue, is in favour of the emotional origin of the symptoms, although, of course, factors of suggestion are not entirely absent. The emotion of fear in this patient during civil life always produced cold sweats, palpitations, and tremors of the limbs—just as in the case of a patient subsequently suffering from functional paraplegia it used to "take him in the legs" and he would feel weak at the knees. The period of incubation in some cases seems to correspond to the time during which the patient is struggling, with a certain degree of success, to repress the painful emotional memories and to remain "captain of his soul." The final outbreak of the symptoms represents the partial failure of this effort of repression, or rather is a condition of the success of the *psychological* repression. The symptoms are "convertion" symptoms, in Freud's sense of the term—i.e., they represent painful emotion converted into physical innervations.

With a certain class of patients, a more detailed form of mental analysis is necessary. In these cases the nervous breakdown is partly due to earlier mental worry, and the "active service" element is simply the last straw. The patient's mind is a battlefield of conflicting emotional tendencies, many of which he himself fails to recognise. By long talks with him, following up thread after thread in the association of his ideas, one can recall repressed memories of earlier epochs in his life, showing him the true emotional significance of them and their connexion with his present disability. In this way the patient learns to understand himself, and therefore I would call the method "*autognosis*." Self-knowledge brings with it self-control in the psychic domain. An analysis of the patient's dreams is often of the greatest help in this method. Indeed, the dreams of some of these patients are so terrifying that they have to be dealt with, and the quickest way to exorcise them is to analyse them—i.e., to trace the different parts of the dream back to their source in the patient's earlier life (by the method of "free" association), and so to discover the underlying unconscious dream thoughts which have been enjoying a disguised or distorted fulfilment in the dream itself.

[1] Psychoneuroses and Psychotherapy, pp. 269, 270.

Treatment.

I now come to a therapeutic method which I have found to be especially valuable in dealing with *early* cases of shell shock exhibiting pronounced symptoms of functional nervous disorder, such as functional mutism, deafness, paralysis, tremulousness, &c., accompanied by more or less extensive amnesia. It is a form of hypnosis, but free from the defects attaching to the ordinary use of that method. To explain by an example:—

Here is a patient who was blown up and buried by a shell explosion two days ago and lost consciousness. On regaining consciousness some hours later he found that he was quite dumb, and also had lost all recollection of the shell explosion and of the events immediately following thereon. In other words, he is functionally mute and has retrograde amnesia. His memory for other recent experiences is also vague, but he is in full command of gesture-language and can write down on paper all that he wishes to say.

I interview him alone in my office and tell him in a tone of conviction that I shall restore his speech to him within a few minutes if he will do exactly what I say. I then tell him to lie down on a couch, close his eyes, and think of sleep. I urge him *to give himself up to sleep*, to let sleep come to him, as it assuredly will. I tell him that he is getting drowsy, his limbs are getting heavy with sleep, all his muscles are relaxed, he is breathing more and more slowly, more and more deeply. Above all, that his eyelids are getting heavy, as heavy as lead, that he feels disinclined to open them, that he cannot open them however hard he tries. At this stage, which generally supervenes within two or three minutes, he really cannot open his eyes. This is a stage of very light hypnosis quite sufficient for my purpose.

I now tell him that the moment I put my hand upon his forehead he will seem to be back again in the trenches, in the firing line, in the fighting, as the case may be, and will live again through the experiences that he had when the shock occurred. This I say in a tone of absolute conviction, as if there is not the slightest shadow of possibility of my words not coming true. I then place my hand on his forehead. He immediately begins to twist and turn on the couch and shouts out in a terror-stricken voice. He talks as he talked at the time when the shock occurred to him. He really does live again through the experiences of that awful time. Sometimes he speaks as if in dialogue, punctuated with intervals of silence corresponding to the remarks of his interlocutor, like a person speaking at the telephone. At other times he indulges in imprecations and soliloquy. In some cases he is able to reply to my questions and give an account of his experiences. In others he cannot do so, but continues to writhe and talk as if he were still in the throes of the actual experience. *In every case he speaks and acts as if he were again under the influence of the terrifying emotion.* It is as if this emotion had been originally repressed, and the power of speech with it, and is now being worked off and worked out.

Abreaction.

This process of "working off" repressed emotion is what Freud calls "abreaction." In my view it is the essential therapeutic process in dealing with the majority of war psychoneuroses. The original shock caused a *dissociation* of consciousness—i.e., an apparent suppression of a certain series of memories, and of a certain motor function (speech). Now, without accepting Freud's sexual theory of the origin of the psychoneuroses, for which I have never been able to find any convincing evidence (i.e., as a universal pathogenic factor), I *do* accept his theory of the cause of mental dissociation—viz., that it is the result of mental conflict and involves repression of emotional states. The repression of any emotion at its inception involves the danger of dissociation, the ideas accompanying the emotion being then more ready to split off from the rest of the mind and pursue a subconscious life of their own.

In most cases of nervous shock caused by shell explosion a state of intense fear is aroused in the patient's mind, which, from its very magnitude, produces loss of self-control and apparent loss of consciousness. There is no real loss of consciousness, but the attempted repression and control of the fearful emotion at its inception brings about a splitting of the mind, which appears later as an amnesia of greater or less extent, often involving other losses of function also, such as dumbness, deafness, tremulousness, or paralysis. The fact that under light hypnosis, and with the appropriate suggestions, these memories return, together with the lost voice, hearing, &c., is evidence that they were not abolished at the time, but were simply split off from the main personality. It is also evidence that the shock worked mentally rather than by its accompanying *physical* concussion (which is often absent).

In my method, then, the patient goes through his original terrifying experiences again, his memories recurring with hallucinatory vividness. It is this which brings about the return of his powers of speech, and not direct suggestion, as in the ordinary method of hypnosis.

My second modification of the ordinary method is in my manner of awakening the patient. Remembering that his disability is due to a form of dissociation and that in some cases hypnotism accentuates this dissociation, I always suggest at the end of the hypnotic sleep that he will

remember clearly all that has happened to him in this sleep. More than this, I wake him very gradually, talking to him all the time and getting him to answer, passing backwards and forwards from the events of his sleep to the events in the ward, the personalities of the sister, orderly, doctor, and patients—i.e., all the time re-associating or re-synthetising the train of his memories and interests.

By the process of *abreaction* I remove the underlying *cause* of the patient's original dissociation, and in attacking this cause I cannot be accused of merely treating symptoms.

I agree entirely with Pierre Janet that only hysterical patients can be hypnotised—in fact that, as Charcot said many years ago, "hypnosis is an artificial hysteria." It follows from this that as the patient improves under treatment he should become less and less hypnotisable. This is the case with my form of the method. Hypnotism has been brought into disrepute by those seekers after the marvellous who have intentionally split up the personality of their subjects more and more in order to get ever more wonderful and abnormal manifestations from them.

Using this modified form of the hypnotic method, one can abolish that tendency towards "*equivalents*" which Janet mentions as one of the three stigmata of hysteria (the other two being *suggestivity* and *distractivity*). By this is meant the tendency which the patient shows to suffer from another functional symptom as soon as his original symptom is removed by suggestion under hypnosis. For example, a mute may develop headaches or gastric symptoms as soon as he has been made to speak by suggestion under hypnosis. By using "abreaction" this tendency is completely eliminated. The use of suggestion *without* hypnosis quite fails to remove this tendency to develop equivalent symptoms. The equivalent symptoms are often so vague that they are not noticed at the time, although they are none the less disabling.

Results of Treatment.

The hypnotic method is needed only for the very small minority of cases that arrive at an advanced neurological centre—only for those showing so-called major hysterical symptoms. In two series of 1000 cases each I treated 173, or 17·3 per cent., in the first, and 132, or 13·2 per cent., in the second by means of hypnosis. In these two series there were altogether 121 cases of loss of speech, or hysterical mutism. I succeeded in curing *every single one of these cases*. Many of them were deaf as well as dumb. These were given a paper of instructions to read, in which they were told to lie down, close their eyes, and give themselves up to sleep. When such a patient showed by the calm look on his face that he had reached a quiet frame of mind, I would suddenly and unexpectedly bang two books together near him, and have the pleasure of seeing his eyes flicker, and then find that he could hear. I could then continue the treatment by word of mouth in the ordinary way. Curiously enough, these deaf-mutes were the easiest of all my cases to treat.

Of course, there are some patients who are ready to malinger with major hysterical symptoms. I caught out 28 such patients in my first series of 1000 cases, and induced them to confess. But this is, happily, a very small proportion—less than 3 per cent.

If, finally, the modified hypnotic method is limited in application, wherever possible, to *one* treatment only, all the drawbacks with which the ordinary hypnotic method is beset are evaded. I only applied the method to the more severe cases, those that had later to be evacuated to the base.

Nevertheless, in such apparently severe cases as those of functional paraplegia this method was not found to be necessary. Vigorous persuasiveness was sufficient to produce a cure. In some of the lighter cases of mutism also this was found sufficient.

Stammering is much more difficult to cure than mutism. The patient can more easily cling to the first symptom than to the second, and every hysteric clings to his symptoms. But in several cases I have produced a complete cure, and a decided improvement in others. In several cases where the patient had stammered in civil life I was able to trace the stammer back to a shock in early life, in the first few years of childhood, and under hypnosis I was able to call up the experiences with hallucinatory vividness before the patient's mind. The stammering was not completely cured thereby, because it had become the habit of a lifetime, but this recall of the shock was the first necessary step towards a cure.

Another Illustrative Case.

As a further illustration of my method I will describe the case of an officer, aged 25 years, whom I treated in France in December, 1916, and whom I happen to have again under my care at Craiglockhart in May, 1918.

He had been sent into my neurological wards on account of his complete inability to stand shell fire, having the irresistible impulse to rush to his dugout and crouch down there the moment shells began to fall in his neighbourhood. Earlier in the year (1916) he had been wounded during an advance and had been left out in No Man's Land under continuous shell fire for several hours. He gave a history of great timorousness and extreme weakness of memory during his youth. I learnt from him that he had been nearly drowned at the age of 3 years, according to what his mother had told him. He himself, of course, could remember nothing of the incident. I should also add that he exhibited many psychasthenic symptoms—e.g., he would begin to count the squares round the top of the stove in his ward, and find that he could not stop counting them. He would be impelled to count them hundreds of times.

I hypnotised this officer and then directed his attention back to the drowning incident at the age of 3 years. He at once began to live again through this incident, gasping with terror as he again, in memory, fell into the water. He described the whole event with such a wealth of detail that it was difficult not to believe that he had been taken straight back to this early period in his life and was living again through the terrifying experience. Later on, he re-experienced with hallucinatory vividness the incident of his baby brother's funeral, seeing again the coffin being lowered into the grave and feeling the desperation of grief *as a present emotion*. He was 18 years old when this funeral took place.

I concluded from these and other results of the hypnosis that the patient's memory was intact, but that certain factors were interfering with the power of recall—viz., the very strong emotional tone of many of these memories, combined with repression of them following upon mental conflict. The "abreaction" of these painful memories in the hypnotic state—i.e., the working off of their emotional accompaniments—should therefore prove beneficial to the patient's powers of memory and to his general mental condition. This was found to be the case, and the patient appeared quite a different, and certainly a much more normal, person after the treatment.

A minor point of interest arising out of this case is that the patient was readily hypnotised in spite of his psychasthenic symptoms. Some authorities have held that psychasthenics are not hypnotisable.

In May of this year I learn from this patient that his mother vouches for the accuracy of his revived memories of the drowning incident in every particular. He is again in hospital suffering from certain neurasthenic symptoms, but he has completely recovered from his previous hysteria. He has done a year's duty since he was with me in France.

Other Treatment.

General hygienic measures are, of course, necessary in the after-care of severe cases, and suffice for the entire treatment of the largely preponderating light cases. Regularity is insisted upon in all habits—alimentation, excretion, sleep, exercise. The patients are put on physical drill and sent for short route marches. Many do light duty in the wards or in the grounds of the hospital. But to the "gospel of work" is added the gospel of cheerfulness and hope.

For insomnia suggestion treatment at night is often very efficacious. The patient can often be soothed to sleep and incidentally taught how to employ auto-suggestion in this case.

Only very rarely have I found it needful to *isolate* patients. But this device succeeded in the case of three patients showing persistent tremors of the head, where every other method had failed.

Summary.

The essential therapeutic agent in the case of *hysteria* caused by shell shock is "abreaction," or the working off of the repressed emotion caused by the shock. Mental analysis is a means to this end, and light hypnosis, applied under proper safeguards, is the quickest and most effective method of effecting this analysis, where amnesia is present and the case is seen early.

For cases of *neurasthenia*, which are the more numerous and involve emotional preoccupation often dating back many years, mental analysis and re-education, without hypnosis in any form, are the needful agents, although the abreaction of the original emotional disturbance or disturbances is again essential.

In both classes of cases the arousing of *sthenic emotion* in the patient's mind is an important adjunct in the cure, both in the form of enthusiastic confidence in his doctor and expectation of a complete recovery, and also in the form of

vivid interest in some form of occupation in the stage of convalescence, during which the mind becomes more unified and consolidated.

I have hitherto not mentioned *rest*, which is, of course, also fundamental. But no complete rest is possible while the mind is obsessed with bottled-up emotion. This emotion must be completely worked off, and then true rest will come. The preoccupations of the neurasthenic also must first be dealt with if any form of rest cure is to produce good results.

After three and a half years of work with nerve patients in military hospitals in Egypt, England, and France, during which over 4000 cases have passed through my hands, I feel no hesitation in saying that mental analysis is the ideal method of treatment, provided that it is carried far enough to produce true abreaction of emotional states. As an aid, and as a sort of short cut, the special form of hypnosis which I have described is very useful in early cases showing major hysterical symptoms.

In conclusion, I should like to thank Lieutenant-Colonel C. S. Myers, F.R.S., R.A.M.C., for his unfailing encouragement and most helpful advice as consultant psychologist in his frequent visits to my wards in France.

May 29th, 1918.

ON THE DIFFERENTIAL DIAGNOSIS OF THE DYSENTERIES:

THE DIAGNOSTIC VALUE OF THE CELL-EXUDATE IN THE STOOLS OF ACUTE AMŒBIC AND BACILLARY DYSENTERY.

BY J. GRAHAM WILLMORE, M.R.C.S., L.R.C.P. LOND.,
CAPTAIN, R.A.M.C. (T.C.);
AND
CYRIL H. SHEARMAN,
CAPTAIN, R.A.M.C. (T.C.).

IN a paper on Dysentery published in 1913 by Savage and one of us,[1] it was pointed out that dysentery, from its first authentic record in the days of the Athenian pestilence during the Peloponnesian War up to the present time, has been *the* scourge of armies in the field, and that it has been responsible for more sickness, invaliding, and military waste than any other factor.

Scope of Investigation.

The greater part of the present paper was written by us in the spring and summer of 1916, and the results to be set forth in the bacillary section were based upon the microscopic and cultural examination of a series of 1165 cases (43 fatal) admitted to a general hospital in Egypt, from April 30th, 1915, to April 30th, 1916. As many stools as possible were plated out on a specially modified MacConkey's medium, and all the fatal cases were submitted to autopsy.

Unfortunately, our collaboration was interrupted by the recall of one of us (C. H. S.) to Government service in Australia, in the late summer of 1916, before we were able, owing to lack of amœbic material, to complete our paper together for publication.*

Since then a further very large series—though we have not the exact figures to hand—has come under our observation. This series included many cases of acute amœbic dysentery, and has been examined by one of us, who had had in addition the experience of 14 years' residence in Egypt and at El Tor upon which to draw. Any criticism, therefore, which may be directed against the amœbic part of this paper must be held to refer only to that one of us (J. G. W.).

Infantile diarrhœa, due, practically speaking, in Alexandria to the *B. dysenteriæ*, levies an appalling toll amongst Egyptian babies at the present day.

Amœbiasis, on the other hand, is a disease of protozoal origin, by reason of which it is much less infectious than bacillary disease, but immunity to it is less easily acquired and less complete.

It thus follows that the lower class Egyptian with his dirtier habits constantly exposes himself to both infections, but succumbs, as a rule, to the one only, unless his constitution has been previously strained by excessive hardship or disease. The better class Egyptian, on the other hand, thanks to his cleanlier habits, is usually exposed only to the bacillary infection, against which, owing to its far greater infectivity, precautionary measures are more difficult to apply.

The conclusion at which we arrived together—namely, that a diagnosis between the two great types of dysentery, amœbic and bacillary, can be made not only more rapidly but even with greater accuracy by simple direct microscopic examination of the stools than it can by cultural methods—has been strengthened by this further study and by a consideration of the results published by independent workers, particularly Bahr, Wenyon and O'Connor, Ledingham and Mackie, to mention only a few with whose work we are most familiar.

The results in particular of the investigations conducted by or under the ægis of the Medical Advisory Commission have established beyond all manner of doubt the contention which we, in 1915, were almost alone in upholding—namely, that bacillary dysentery has been, and is, the predominating and the more severe type of the disease in the whole of the Near Eastern area of operations.† To this conclusion we were led by investigations the object of which was to determine whether or not two diseases so distinct in their etiology and morbid anatomy would give rise in the dejecta to different types of cellular exudate, each peculiar to its own class—in other words, to determine whether a diagnosis could be made without identifying either the one or the other causal organism.

Importance of Early Diagnosis.

It is our purpose to show in this paper that—

1. Pure amœbic dysentery—i.e., uncomplicated by coexistent bacillary infection—gives rise to a characteristic exudate in the stools.
2. Bacillary dysentery, whether complicated by amœbic infection or not, also gives rise to a cellular exudate of specific character in the stools.
3. The finding of *Entamœba histolytica* in the midst of such a "bacillary" exudate indicates, not that the case is one of simple amœbic dysentery, but that a double infection is present, although all attempts to isolate dysentery bacilli may fail—as they do in many instances even when the case is one of "simple" bacillary dysentery.
4. In such cases of double infection, which are of more frequent occurrence than has been supposed, the diagnosis of the amœbic moiety can be made only by finding *E. histolytica*, for the reason that the exudate associated with the latter is comparatively so scanty and insignificant that it is masked by the overwhelming bacillary exudate. While the consequences of neglected amœbic infection may be disastrous, it is of still more immediate importance that bacillary dysentery should receive prompt recognition and appropriate serum treatment, for the following reasons:

(*a*) In fulminating cases, the time limit during which treatment is of any avail is much shorter in bacillary than it is in amœbic cases.

(*b*) In severe cases the patient rapidly becomes soaked with bacillary toxin, which results in severe degenerative changes occurring in myocardium, liver, and kidneys.

(*c*) The earlier a bacillary case is treated with *massive* doses of antiserum the more prompt and complete is recovery. While a delay of a day or two in instituting emetine treatment usually makes little difference to an amœbic case, a like delay in administering antitoxin to a bacillary patient may make all the difference between the abortion of the illness and months of invaliding and abdominal misery.

(*d*) Antidysentery serum is harmless to an amœbic patient; emetine, on the other hand, seems to us, as a result of our experience, to be a highly risky drug to administer to anyone whose myocardium is degenerated. As this does not occur in simple amœbic dysentery there is little risk in administering it in large doses to such cases, and even less to healthy carriers.‡

Pathology.

In order that the principle on which this cyto-diagnosis is based may be more fully understood it is necessary to give the briefest possible account of the pathology of the two diseases.

* From September, 1915, up to July, 1917, I (J. G. W.) was unable to obtain amœbic material in quantity sufficient for my purpose from European troops. All my cases of amœbic infection occurred in Egyptians of low class, among whom alone does the amœbic type of dysentery predominate. The explanation of this would appear to lie in their relative immunity to infection by the dysentery bacilli—a fact which is paralleled by their well-known immunity to organisms of the enterica group, which they have acquired through generations of existence in defiance of the most elementary rules of personal hygiene.

† We do not deny that there was a great deal of amœbic dysentery also in the summer of 1915, but not later.

‡ It must not be forgotten that *Entamœba coli* may coexist, as a harmless commensal, with *E. histolytica* or any of the dysentery bacilli.

By the term "dysentery" we understand a clinical condition the essential characteristic of which is the destruction of any part of the mucosa of the large intestine by one of the specific infections, amœbæ or dysentery bacilli; only those cases which showed evidence microscopically in the stools of such destruction in the form of mucosal sloughs and cellular exudate are included in the tables of our cases. Thus it is likely that many cases of early infection by dysentery bacilli which were recognised as such by the clinicians and treated immediately by them with massive doses of antiserum—with consequent abortion of the illness—figure in our returns simply as cases of enteritis. This was due to the fact that during the rush of the epidemic the pressure of work prevented the stools of all cases being examined until some days after the admission of the patient to hospital.

Pathology of Amœbic Dysentery.

Amœbic dysentery is due to infection by the *Entamœba histolytica*, and by it alone. No other amœba is capable of causing this disease, and it requires no help from secondarily infecting organisms of the bowel in the production of its lesions.

The life-history of this parasite is briefly as follows:—

The encysted form is swallowed with the food. Arrived in the small intestine, the digested juices there dissolve the capsule and set free the small daughter amœbæ, which make their way to the large intestine and thence down the lumina of the mucosal glands into the submucosa. There they grow into the adult or vegetative form, multiply by binary fission, and, in our opinion, give rise to a direct colliquative necrosis of the submucosa and muscularis mucosæ by means of a proteolytic ferment which they are able to secrete.

Direct communication with the lumen of the gut—i.e., ulceration—is only attained when either the solvent attacks the intercellular cement of the mucosa or the necrosis extends far enough to interfere with its blood-supply. According to which occurs first the mucosal cells are shed singly or *en bloc*, and an irregular ulcer with ragged, undermined edges is formed. The loss of substance is far greater in the submucosa than in the mucosa, as large vegetative amœbæ are found in the greatest numbers there; often sinuses lead from one ulcer to another under bridges of perfectly healthy mucosa.

As the amœbæ approach the surface of the mucous membrane again they divide more and more rapidly, and consequently become smaller and smaller until on the surface of the gut they assume the "*minuta*" form. Many of them now encyst, and they are passed out of the body in the stools as cysts or *E. minutæ*. It is worthy of note that the *E. minutæ* § produce no destruction of the tissues, and consequently no symptoms of dysentery; a fact which is distinctly in favour of the larger, or older, amœbæ producing a proteolytic ferment.

Adami was the first to point out that the reproductive and the higher functional activities of cells are mutually antagonistic; the more embryonic the cell the more readily does it multiply, and thus the more rapid is the growth of a neoplasm composed in greater part of cells of embryonic type. The smaller size of these amœbæ is due to their more rapid division, which has used up all their reserve of energy; consequently none is left for the development of that particular function which differentiates *E. histolytica* from all other amœbæ.

It has never been shown that the entamœbæ produce a diffusible toxin, or that they are capable of exerting any poisonous effect other than the proteolysis of cells in their immediate neighbourhood.

In consequence, the onset of the disease as a rule is insidious—it may be even unnoticed—and it is not until a comparatively large area of the gut is involved that the patient becomes at all acutely ill. It will thus be noted that the mucosal cells are in general healthy, apart from the areas of actual infection, while at autopsy the typical picture seen is one of areas of circumscribed necrosis, dotted like islands in the midst of healthy pink mucosa.

Now-a-days, when the emetine treatment is so universally adopted, cases where the bowel has undergone "gangrene en masse" are, fortunately, so rare as to warrant only passing notice. This condition is brought about by such an extensive amœbic invasion of the submucosa—and even the muscularis—with consequent thrombosis of blood-vessels, that the blood-supply of the bowel is cut off as effectually as by multiple thrombosis arising from any other cause.

The result is that the entire thickness of the bowel over a greater or lesser extent becomes gangrenous, and is passed as stringy black sloughs having a horribly fœtid odour. On very rare occasions it has even been impossible to remove the colon at autopsy, as all that remained to represent it was a slimy, stringy, black mass lying in a bath of corruption. Unless one had actually seen such a case it would be inconceivable that a man could survive long enough for his intestines and his peritoneum to attain such a state.

Sellards and Baetjer have shown that fatal cases of amœbic dysentery often terminate with a blood infection by members of the *Streptococcus fæcalis* group.

There is nothing astonishing in this if one considers how often the intestinal bacteria invade the body before death in different chronic and subacute diseases. The astonishing part is that it does not occur more frequently in amœbic dysentery—a disease in which there is such an extensive solution of continuity of the mucosal barrier. The point which we wish to emphasise is that in the vast majority of cases of non-fatal amœbic dysentery no such invasion of the blood stream can be demonstrated by hæmoculture.

This may be due to one or two causes acting together or separately.

In the first place, the liver may act as an efficient bacterial filter; in the second, the bowel itself is probably endowed, even when diseased, with a high immunity against just such organisms. Wright has shown that different parts of the body possess different degrees of resisting-power against pyococci. It seems reasonable to suppose that this local immunity acquired by countless minute inoculations with the bacteria-containing fluid in which the mucosa has been bathed since birth is sufficient to protect not only the body against invasion by these bacteria, but even the mucosa itself when the latter is partially destroyed by amœbæ.

In amœbic dysentery only when extensive areas are killed by interference with their blood supply does any secondary infection of the mucosa take place, just as a limb may become affected by wet gangrene after the blocking of its blood-supply. When, however, a pathogenic organism, such as a dysentery bacillus, which is a stranger to the mucosal barrier, and against which the mucosa is in consequence not immunised, arrives on the scene in sufficient numbers and virulence immediately its destructive properties come into play.

When sections are made through the edges of early amœbic ulcers, and more particularly when the unbroken amœbic nests in submucosa or liver are examined histologically, the salient point to strike the observer is the absence of the usual cellular infiltration characteristic of inflammatory reaction.

This is all the more striking when a comparison is made with the corresponding sections of early bacillary dysentery which is an inflammatory disease.

Again, the so-called amœbic liver "abscess," when sterile, is not an abscess at all. It is a primary colliquative necrosis of hepatic tissue, which is broken down and changed by a proteolytic enzyme from protein to albumoses and peptones; the patient's symptoms are due to the absorption of these poisons directly into the blood stream and can be reproduced experimentally by the intravenous injection of peptone.

To sum up: the pathology of histolytica amœbiasis is a primary degeneration due to the chemical digestion of the cells in the *immediate* neighbourhood only of the amœbic enzyme. It is not a primary inflammation with consequent degeneration; any inflammation which occurs is due to secondary microbic infection, is generally not severe, and takes place late in the disease.

The nature of the cellular exudate in the stools and in the uncontaminated liver "pus" is in entire accord with this basal fact of its pathology.

Pathology of Bacillary Dysentery.

Very different from the amœbic lesions are the changes which occur in bacillary dysentery. The infecting agents belong to a different kingdom.

The two diseases are so totally distinct that the only excuse for grouping them both under the heading of "Dysentery" is that of historical usage. In logic it were as reasonable to group cancer and tuberculosis of the intestine under the same heading because they may both give rise to what used to be called the "bloody flux."

Whatever may be the route of infection the essence of the pathology of bacillary dysentery is the intense diffuse catarrhal inflammation of the mucosa, which according to the severity of the attack may resolve or may go on to degenerative changes, such as coagulation-necrosis and sloughing. It is a primary inflammation of bacterial toxic origin, with all the cardinal signs of this condition—viz., "*rubor, tumor, calor, dolor et functio læsa.*"

The process is essentially one of diffuse destruction of the superficial layers of the mucosa, accompanied by œdema, large immigration of leucocytes, diapedesis of blood cells, and hæmorrhagic extravasation—such as is seen in all cases of acute bacterial inflammation of tissue. The immigration of polymorphs is an especially noteworthy feature. At autopsy the appearance of the intestine in any case of bacillary dysentery will vary with the intensity of the infection and the length of time the patient has survived it.

In the so-called fulminating ileo-colic dysentery, the entire surface of the lower part of the ileum and large intestine (*always excepting Peyer's patches and the appendix*) is seen to be the site of intense inflammatory change. No part escapes, as it does in amœbic dysentery; the bowel wall is œdematous, enormously thickened, deep plum-red in colour, and the mucosa may resemble the surface of a large granulating wound. A case of this intensity is more likely to be met with in patients who happen to be affected with renal disease of long standing, and death takes place from poisoning before the changes later to be described have had time to occur.

If the patient survives this stage, the superficial layers of the entire mucosa undergo coagulation-necrosis, become bile-stained, and are replaced by a green diphtheritic false membrane which may entirely hide the red granular layer underneath it. Here or there smaller or larger areas of this membrane may have sloughed, disclosing buds of granulation tissue of greater or lesser extent. Coincidently, small but numerous intramucosal hæmorrhagic extravasations take place.

If the patient again survives this stage small superficial ulcers, affecting particularly the summits of the valvulæ conniventes and mucosal folds, are formed. The minutely eroded, pinkish-grey "coraline" appearance of these ulcers, which run transversely across the bowel along the ridges of the mucosal folds of the colon, and are often present in large numbers, confers a very characteristic appearance. The sloughed mucosa is gradually replaced by well-formed and vascularised granulation tissue, and later by fibrous hyperplasia; if the patient recovers entirely the large intestine becomes shrunken into a thick-walled firm tube, with narrowing of its lumen and permanent damage to its functions.

Again, the ulcerative process may continue and spread, with the result that the gut wall may be honeycombed with myriads of small ulcers and so finally resemble a piece of red porous rubber.

§ They never contained red blood cells.

These ulcers, in spite of the fact that they may give rise to the so-called "worm-eaten condition," can easily be distinguished from the amœbic ulcers by the fact that they are more superficial, more regularly circular or oval, and have cleaner cut edges than the ragged undermined amœbic ulcers. Their depth will vary with the amount of fibrous change that has taken place in the bowel wall around them, which may be so great as to make them appear deeper than they really are. Whereas the thickened peritoneum may often constitute the base of a healed amœbic ulcer, it is extremely rare to find a bacillary ulcer penetrating deeper than the muscularis mucosæ. In all our experience we have yet to come across a case of perforation or peritonitis in pure bacillary dysentery.

Varying with the intensity of the infection, certain areas of the intestine are affected more than others.

Rogers states that the descending colon and rectum are more frequently involved than any other part. In our experience, on the other hand, the cæcum, first part of the ascending colon, and the flexures have been more profoundly affected than the other parts of the large gut.

When complete recovery has occurred after a less extensive infection than that first described the mucosa is often seen to be atrophied and stained a dirty slate-grey colour as a result of the diffuse intramucosal hæmorrhagic extravasation. In healed amœbic ulcers, on the other hand, this staining is seen only in and immediately around the cicatrices of the ulcers.

Concurrently with the local changes are those produced in heart, liver, kidneys, adrenals, and probably the nervous system, due to the absorption of the toxins formed in the gut by the dysentery bacilli.

In bacillary dysentery, as in diphtheria, the patient dies of intoxication. It may be definitely stated that as a general rule dysentery bacilli do not invade the blood stream, except during the stage of premonitory fever before diarrhœa begins. On one or two occasions certain observers have claimed to have isolated them by blood culture; but this invasion of the blood must be looked on as an accident in the course of the disease, and the occasions on which a general dysenteric bacillæmia takes place are so rare that the probability of its occurrence is negligible.

Just as the amœba is responsible for the ulcers of amœbic dysentery, so, in our opinion, is the dysentery bacillus alone accountable for the damage to gut and general system. We do not deny that secondary infection of the blood stream may and does take place occasionally in the course of both diseases, ‖ but we controvert the idea that any such infection is to be regarded as a regular concomitant.

It has been known for many years—in fact, since Todd first worked out the poison of Shiga's bacillus—that the "non-mannite-fermenting" type of dysentery bacillus produces a soluble toxin. Whether this toxin is really extracellular and diffusible from the first or whether it becomes so owing to a rapid breaking down of the bacillary bodies, and consequent liberation of endotoxin, is a matter of no moment. The fact remains that a filtrable toxin is easily demonstrated in cultures of this bacillus.

It has been the fashion to deny to the mannite-fermenting group of dysentery bacilli this attribute of being able to produce a diffusible toxin.

Everyone who has had experience of dysentery due to the mannite-fermenting type of bacilli must have been forced to the conclusion that a similar and equally virulent toxin was at work in these cases, as in those in which Shiga's bacillus was the morbific agent. The clinical symptoms are the same, and the degenerative changes in the organs seen at autopsy are indistinguishable from those seen in cases of death from Shiga's bacillus.

In May, 1913, one of us (J. G. W.), using a slight modification of the technique devised by the late Sidney Rowland to extract toxic nucleo-albumen from *B. pestis*, succeeded in obtaining from different mannite-fermenting strains of *B. dysenteriæ* a toxin which killed rabbits in doses of 0·01 g., in the same way as did the living bacilli. This toxin was afterwards used by one of us with very good results in the manufacture of antidysenteric serum from horses. This point is mentioned here to prove that whatever the type of infecting dysentery bacilli similar toxic changes occur in all.

Diagnosis Based on the Cytological Picture of the Stools.

It will thus be seen that it is easy to diagnose between the two great types of dysentery when they reach the post-mortem table, so definite and peculiar to each is its morbid anatomy. We were led, therefore, to hope that on *a priori* grounds the differences in the nature of the exudate and desquamated cells found in the stools of each variety would be sufficiently constant and characteristic to constitute a basis for differential diagnosis at once reliable and rapid.

Our investigations have led us to the conclusion that it is possible to arrive at such a diagnosis, based entirely on the cytological picture peculiar to each type of the disease.

The character of any given stool will depend upon the particular stage of the disease at which that stool has been evacuated. It will depend to a much less extent upon the nature of the food which the patient has taken, in that in the vast majority of cases both types of patients—amœbic and bacillary—will have been treated on similar dietetic lines; further, our examination is restricted to any sloughs, bloody mucus, &c., which may be mixed with the fæcal matter.

‖ Embolic suppurative nephritis (renal pyæmia) was a not uncommon termination of fatal cases of bacillary dysentery among pilgrims at El Tor. A form of *B. coli* was always isolated from the emboli—never a dysentery bacillus.

Cyto-diagnosis in Amœbic Dysentery.

If some of the bloody mucus from a case of "simple" amœbic dysentery be examined microscopically (under the $\frac{1}{6}$" and $\frac{1}{12}$" objectives) the first thing to strike the observer will be the scantiness of the cellular exudate, though red-blood corpuscles may be very abundant. This point has particularly impressed us when examining material taken from the surface of an ulcer at autopsy.

Another salient characteristic is the preponderance of mononuclear cells over polymorphonuclears, a feature which contrasts sharply with the picture seen in bacillary dysentery. (Compare Figs. 1 to 9 with 12 to 15.)

Next to the scantiness of the cellular exudate the most noteworthy element in the film is the picture presented by the actual cell components—most of them look half-digested, and have a "mouse-eaten" appearance (Figs. 10 and 11). The process evidently begins at the periphery, and the nucleus is the last to be involved. In many cases groups of nuclei appear to become agglutinated by means of their semi-digested surrounding cytoplasm.

The process is apparently a slow one, the cytoplasm being gradually digested and dissolved and the unchanged nucleus being left bare or clothed merely in a narrow strip of ragged cytoplasm. Fig. 5 shows this very clearly; the stool was obtained 24 hours before the death of the patient, an Egyptian, from acute amœbic dysentery. At autopsy the entire large intestine was found to be studded from end to end with amœbic ulcers of all shapes and sizes; non-agglutinating vibrios were obtained in culture, but no dysentery bacilli could be isolated. Of far greater value in demonstrating the absence of bacillary infection in this case was the healthy pink colour of the mucosa between the ulcerated areas. (The diagnosis was made at first from the nature of the cellular exudate alone, though amœbæ were found later.)

We have recently had occasion to examine one of the very advanced cases of gangrenous amœbic dysentery described earlier in this paper. (Figs. 7 and 11.)

Curiously enough, this patient (an Egyptian) also harboured non-agglutinating vibrios in his intestines, but at autopsy there was no evidence of cholera and no vibrios could be isolated from the small intestine. Here again it was possible to make an ante-mortem diagnosis of the condition of the large bowel by means of the stringy black sloughs, the appalling fœtor of the stool, and the fact that microscopically hardly any polymorphonuclear cells were seen—nothing but amorphous débris apparently more or less completely digested, and a few nuclei from which all the cytoplasm had been stripped. Many of the nuclei, even, were semi-digested and degenerated; but of all the structures involved they were evidently the most resistant to the degenerative force in action.

In our opinion, this type of degenerative change can be explained only on the supposition that in amœbic dysentery no toxin is at work in the organism at all comparable to that produced by the dysentery bacilli.

As will be shown later, the cells in a bacillary stool give evidence of being poisoned *en bloc* and undergo rapidly the changes characteristic of toxic necrosis and autolysis, the nucleus being among the first parts of the cell to be affected.

Further, the fatty changes to be described as occurring invariably in cells composing the bacillary exudate are never seen to anything like the same extent in amœbic stools, when examined fresh in Sudan III. solution; all that one sees are isolated "lumps" or dots of fat, suggesting that the cells had previously ingested some fatty material rather than that it was of intrinsic cytoplastic origin.

Consequently, all the evidence goes to prove, in our opinion, that every morbid change seen in amœbic dysentery can be explained on the hypothesis of proteolytic digestion of living tissue by the amœbæ.

To sum up the characteristics of a "simple" amœbic stool:—

1. Scantiness of cellular exudate, especially the polymorphonuclear element.
2. Preponderance of mononuclears over polymorphonuclears.
3. Evidence of proteolytic digestion of the cells, beginning at the periphery and affecting the nucleus last.
4. Absence of all phenomena characteristic of inflammatory reaction, toxic necrosis and consequent autolysis.

Cyto-diagnosis in Bacillary Dysentery.

A very different picture is seen on examining microscopically the blood-stained muco-pus from a case of bacillary dysentery, whether in the acute, subacute, or chronic stage.

Here the first feature to strike the observer is the abundance of cellular exudate, composed largely of polymorphonuclear leucocytes. Desquamated and degenerated mucosal cells are also common, but the polymorphonuclear neutrophiles predominate. Blood may or may not be present according to the stage of the disease, whereas it is hardly ever absent from the stools of amœbic dysentery.

The polymorphonuclear neutrophiles show the characteristic changes consequent on toxic necrosis more than any other leucocytes, the eosinophiles less and the lymphocytes least of all. The cell is evidently poisoned *en masse*, and whether the further changes about to be described are directly caused by the toxin or are merely autolytic phenomena resulting from the death of the cell is of no moment. The important point for our purpose is that the process is obviously different from that which takes place in the cells of an amœbic exudate.¶

¶ The nuclei seem to be specially sensitive to the action of this toxin, as the changes described, particularly fragmentation and agglutination of small chromatin masses round the nuclear membrane, and "ringing" of the nuclei, have not been observed by us in similarly prepared films of pus obtained from other sources—e.g., boils—or at least to nothing like the same degree.

A type of cell which is always present, often in large numbers, and which seems to be associated more frequently with bacillary (especially cases which are improving clinically) than with amœbic dysentery somewhat resembles a free resting amœba, and it is important not to mistake it for one. (Figs. 17 to 19.)

There is, in our opinion, little doubt that this mistake has been often made, and that as a result the numbers returned as amœbic dysentery in 1915 were unwarrantably high. Particularly do we consider these remarks applicable to cases of so-called "running amœbic dysentery," often accompanied by a rise of temperature, which responded beneficially to serum treatment. These cells may have also given rise to the diagnosis "post-amœbic colitis."

As these cells are larger than a polymorphonuclear leucocyte, and as the changes in them are much the same as those occurring in other leucocytes, it will be convenient to describe them as a type.
